During the summer it was found that quite a number of the wholesale provision dealers have shipments to make to four large summer hotels located at Swampscott, Mass., which is the next town beyond Lynn. As the daily shipments to these hotels amount to a full load all told, during the four summer months one truck is run to the hotels once per day, delivering to the ho-

specialty of furniture moving by motor truck in the vicinity of Boston. For these long hauls a flat rate is made which includes loading and unloading, but does not include special moving, such as pianos, etc., and packing. The rate is \$1 per mile. Among the firms doing this class of business are H. L. Kincade & Co., of Quincy, who have a 3 ton Frayer-Miller truck, which is used for delivery work in their regular furniture business, as well as for long distance hauls.

FURNITURE MOVING.

Warner & Co., whose main business is packing and shipping, and who formerly had their transportation done by others, have recently taken up the motor truck for their service. About the 1st of March they put a 11/2 ton truck into service, and they have recently added a 3 ton truck to their equipment. Perhaps a specific example of a job will show what the motor truck can accomplish in this line of business. It was desired to move the furniture and contents of a large housekeeping flat from Boston to Ipswich, a town 25 to 30 miles from Boston. It was, of course, necessary to pack much of the crockery, glassware, etc., very carefully. This was attended to by the packers employed by this firm at a flat rate per man per hour. The teams were on hand at about to be handled twice, thus increasing the risk of breakage.

This is by no means an extreme case, as this same firm has carried a load under similar circumstances to New Bedford, which is between 50 and 60 miles from Boston.

### OPERATING COST.

The average consumption of gasoline on the gasoline trucks is at the rate of I gallon per 4 to 6 miles. A gallon of lubricatnig oil lasts from 80 to 90 miles. Most of the concerns operating trucks are of the opinion that these items are so small as to hardly warrant the keeping of a very accurate account, and that the real item of expense is the cost of upkeep, including the cost of tires, broken springs and worn chains and sprockets. The drivers of these trucks are almost entirely recruited from the ranks of the old express wagon drivers, although in some cases specially trained chauffeurs are employed. With very few exceptions all the machines are fitted with either sliding or selective gears, giving three to four speeds ahead. The two speed and reverse planetary has certainly lost considerable ground for this kind of work. Not only that, but the drivers seem to fully appreciate the advantages of using the different speeds

and change them fully as frequently as is advisable.

Perhaps the growth of the business around Boston is largely due to the activity of the agents for one make of truck, who have seen the possibilities of the business and have had the courage of their convictions. This concern formerly was and still is in the manufacture of carriages and wagons, and its members enjoy a wide acquaintance among the express companies in the vicinity. They were able to see what

was wanted, and when the machine came along that they thought was right for their customers they did not hesitate to secure the agency for it and recommend it. Then, after having sold the truck they placed themselves in such a position as to keep their customers satisfied, doing repairs and furnishing replacements promptly, and making moderate charges. The result has been that this firm has almost a monopoly of this line of business in the vicinity of Boston.

# Self Regulating Dynamos for Auto Lighting and Ignition.

BY ALBERT L. CLOUGH.

Now that electric lights have come to be so largely used upon motor cars, there is a decided tendency toward the installation of small direct current dynamos for the purpose of continuously recharging the accumulators required to feed the lamps and sometimes frequently to operate the ignition system as well. A generator delivering a nearly constant voltage, independent of the very wide speed fluctuations of the gasoline motor which drives it, is necessarily required. The centrifugally actuated flyball governor, controlling a friction clutch pulley? has been largely used to maintain the generator speed constant, despite the fluctuations of speed of the car motor, and there has also been slightly used an automatic field rheostat, so arranged as to weaken the generator field current in proportion to the increase of speed and vice versa. In order to accomplish this a centrifugal governor is so arranged as to cut into or out of the field circuit a series of resistances when the speed rises or falls. When this arrangement is correctly proportioned the increase in voltage which would be occasioned by a certain increase of speed may be very nearly counterbalanced by the decrease in voltage occasioned by the weakening of the field, which is brought about by the resistance automatically added to the field circuit by the centrifugal governor's movement, due to the rise of speed, and the e. m. f. delivered is thus kept reasonably constant.

It is not unlikely, however, that automatic mechanical devices, such as these, which involve moving and wearing parts and a certain degree of complication, may ultimately be superseded by regulating tendencies inherent in the generators themselves, and due to special features of design.

Inherent regulation of a direct current generator may be favored to a considerable extent by a proper proportioning of copper and iron in armature and field, and by properly predetermining the degree of saturation of the iron, but in the production of a constant voltage, variable speed generator, advantage is sometimes taken of the phenomena of armature reaction. This is done in the case of one small shunt wound bipolar machine designed for vehicle lighting. The

in involved is crudely illustrated in ompanying diagram, Fig. 1.

#### AUXILIARY BRUSHES.

Two sets of brushes are used, of which a > 15 the main pair. These bear upon the commutator in the usual position for nearly sparkless operation, that is, at or near the neutral points. Brushes cd are an auxiliary pair which touch the commutator on a diameter nearly at right angles to the main brushes. They are, however, not exactly upon this diameter, but are displaced appreciably in the direction of rotation of the

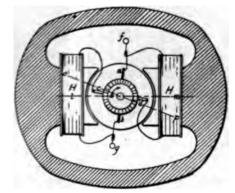

FIG. 1.—INHERENT DYNAMO REGULATION OF VARIED SPEED,

armature. The shunt field circuit is as follows: From one of the main brush leads, near f, it goes through one of the field spools H, and thence to auxiliary brush d, through the armature windings to the other auxiliary brush c, thence through the other field spool H, and finally connects to the other main brush lead near the service binding post g. The auxiliary brushes thus bridge between the two field spools. If c and d were set exactly upon a line at right angles to the line joining the neutral points, at or near which the usual brushes of a bipolar machine are set, there would be no effective voltage acting between them, for the voltage generated in the upper half of the armature would exactly counterbalance that generated in the lower half. If the auxiliary brushes are placed on one side of this perpendicular to the neutral axis, a voltage in a certain direction acts between them, the amount of which depends upon the angle of displacement, and if these brushes are set upon the opposite side of this line the voltage between them acts in the other direction.

The armature and field of this machine are so proportioned that there is a very strong armature reaction; that is, as the current builds up in the armature the magnetic field, which it produces as it circulates in the armature conductors, tends very strongly to shift the field due to the field magnets, with the result that the neutral axis tends to rotate in the direction of rotation of the armature.

#### PRINCIPLE OF REGULATION,

At very low speeds, when the tendency is for the armature current to be low, the auxiliary brushes have a lead in advance of the line perpendicular to the neutral axes *l m*, and a certain voltage acts between them. The connections of the auxiliary brushes to the field circuit are so poled as to cause this voltage to act in the same direction as the main field exciting voltage, and thus to assist in energizing the fields. The result is that when the armature is turning at very low speed the field excitation is very much greater than it would be if the auxiliary brushes were not used, and the voltage very much nearer the desired value.

As the armature speeds up there is a tendency for its current to increase, and increased armature reaction results. At a certain point of speed increase, the line 1 m has rotated until it passes through the brushes cd. Under these conditions no voltage is acting between c and d, and they have no effect upon the excitation, the generator operating on simple shunt excitation. As the speed is still further augmented, and the armature current tends to increase to a higher value, the neutral axis is still further rotated and line I m assumes a position such as o p. Now there is again an effective voltage between brushes c and d, but, as previously indicated, it is in the opposite direction from previously, and now tends to oppose the regular shunt excitation. Despite the high speed, the reduction in field strength is sufficient to hold down the working voltage to a very much lower value than it would have if the auxiliary excitation were not provided. The higher the speed the greater the shifting of line op in the direction of rotation, the greater the opposing voltage between c and d, and the greater the weakening of the effective field. By a proper setting of the lead of brushes c and d the regulating effect can be increased or decreased, and quite wide variations in speed can be very nearly overcome.

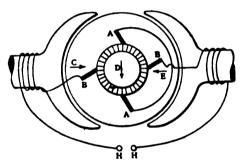

If the evil effects of sparking at the main brushes can be minimized, this arrangement should be of value, as it effects regulation without moving parts, and can always be depended upon so far as it goes.

ANOTHER METHOD OF REGULATION.

Another method of regulation, which has been evolved to secure a constant current through a constant resistance, at widely variable speeds, will here be described, in principle (Fig. 2). This also depends upon armature reaction. To secure the desired results an armature of large iron content and rather heavily wound is used, and the field magnets are of quite small iron section, but

heavily wound with series coils so that they are saturated readily. The pole pieces, on the contrary, are massive and embrace a large polar arc. The brushes A A, which are set as are the main brushes of an ordinary bipolar generator, are here the auxiliary brushes, and are connected together, thus short circuiting through them the armature winding. Brushes B B, which are set on a diameter nearly at right angles to brushes A A, become in this generator the service brushes, and furnish the working current to binding posts H H, through the series fields.

The condition of the magnetic circuit is somewhat more involved than in an ordinary generator. The field coils set up a flux in the ordinary direction from pole piece to pole piece in the direction denoted by the arrow C. This is cut by the armature conductors, which are short circuited by the brushes A A, and currents circulate in the two halves of the armature winding exactly as they do in the armature of an ordinary generator, and produce a cross magnetic flux corresponding to the cross magnetization due to ordinary armature reaction. As the volume of the short circuited current is large, and as the pole pieces are

INHERENT REGULATION FOR VARIABLE SPEED.

very susceptible to it, the cross magnetic flux in the direction of arrow D becomes a very important factor compared with what it is in a machine of usual construction.

The armature conductors in their rotation cut this cross flux D, and a current is induced in them, which is taken off by the working brushes BB to the fields and the external circuit. This current, flowing through the upper and lower halves of the winding, tends also to magnetize the armature core and the pole pieces, and the direction of this flux is along arrow E. That is, this field, which is produced by the armature reaction of the working current, directly opposes the field due to the field magnets. This brings about a very unstable condition of the effective field, which gives rise to the working current. Remembering that the field magnets are of very small cross section, and heavily wound, it is plain that they reach nearly their full saturation before the normal output is attained. The pole pieces and armature core being massive, these parts are at a low density, and an increase of current in the field coils has little influence upon them. Changes of current in the armature acts, however, very powerfully upon these parts at their relatively low degree of saturation

If the machine is working normally and is suddenly speeded up, the cross field due to the currents short circuited by brushes A A increases, and there is a tendency for the armature conductors cutting this field and furnishing current to the working circuit to increase. Upon such a slight increase occurring, its armature reaction along arrow E instantly increases, and the resulting flux tends to counteract and reduce the field magnet flux C, which latter, being diminished, causes a diminution in flux D, and a lessening of the current produced by it in the working circuit. The rise of current in the working circuit is thus limited to a very small value.

A diminution in speed produces actions opposite to those above described.

On account of the small mass of iron in the fields and the large number of field turns, the machine "builds up" to a working condition at quite low speeds.

By shunting a portion of the working current away from the field coils, regulation to varying current strengths can be attained.

# Methods of Providing Against Torque Reaction.

By F. E. WATTS.

In all shaft driven cars there is a tendency, when starting forward from rest, for the rear axle housing and propeller shaft to turn backward. When the hub brakes are applied while the car is moving their reaction tends to turn the axle casing forward. These "torque reactions," as they are commonly called, must be resisted by some member or members fastened to the axle in a sufficiently rigid manner to prevent it from turning out of its usual position more than a limited amount.

Three methods of taking this torque reaction are at present in vogue. Where only one universal joint is used the propeller shaft is commonly enclosed in a tube, and this tube takes the torque. The forward end of the tube is usually fitted with some kind of a universal joint arrangement which secures it to the frame. Thus the torque is transmitted from the rear axle directly to the frame. When the brakes are suddenly applied or the clutch is thrown in abruptly the torque reaction rises to its highest value. It is then imperative that the torsion member be very strong or have some provision for yielding slightly under an excessive stress. In the construction just described the tube must be made strong enough so that it is too rigid to yield any perceptible amount. The only way in which deflection can take place therefore is by compression of the springs in the case of brake application, and by the lifting of the car and passenger weight when the clutch is thrown in.

## SPRINGS AS TORQUE MEMBERS.

This method of taking torque reaction is quite generally used in the smaller cars, but when the motor is much over 30 horse power the stresses become so great that most designers prefer to adopt some other construction.

In quite a few of the smaller cars the torque tube ends just at the rear of the universal joint, and a ball or roller bearing is placed at this point. The torque reaction is then carried by the universal joint. While this construction would seem to be more faulty than the last, from a theoretical standpoint at least it appears to give good service in practice.

For the more powerful class of machines two universal joints are commonly used. The joints are ordinarily enclosed, but the connecting shaft is left bare. A separate torsion member is provided. This has quite commonly consisted of a tube with a ball joint at its forward end, the socket for this ball being secured to a cross member of the frame. The socket is commonly carried in a tubular case between helical springs, so that no matter in which direction the stress comes one of these springs deflects and prevents excessive stresses in the torsion member and transmission parts.

PRESSED STEEL TORSION MEMBERS.

The present tendency is to use torsion members of pressed steel rather than tubular ones. They are usually made of narrow channel section with lattice web, very deep at the rear end and tapering to the end which joins the frame. Sometimes the torsion member is made from two tubes with their rear ends attached to the top and bottom of the driving gear housing respectively, and their front ends joined so that they form a V. Either of these last two constructions gives a light and strong torsion member, but their front ends must be spring supported, as when a single tube is used.

The third method of taking torque reaction is the simplest, and may be the best for certain classes of cars. It consists in making the springs fast to the axle and also to the frame, and letting them take care of the torque reaction as well as the spring support. The propeller shaft is, of course, fitted with two universal joints. Where this is done there must be a very perceptible deflection of the springs when the brake or the clutch is suddenly applied, and this deflection must greatly reduce the maximum stresses in the transmission parts.

While this construction has been used by only a few makers in this country and abroad, they are representative concerns whose practice it is well to watch. It is being used with apparent success on some very powerful cars, and it would seem to permit of a lighter car for a given maximum stress in the transmitting parts than any other construction. It will be interesting to observe whether the circle of adherents of this construction increases.

We would be glad to have any of our readers give their experiences as to the relative amount of wear in the universal joints with different types of construction.

The seventh annual automobile show in Turin, Italy, is to be held April 3 to 24, 1910. The show will again be held in the Valentino Park, and will comprise a motoragricultural and an aerial section.

# Machining an Auto Engine Cylinder.

BY JAMES McIntosh.

The auto cylinder is subjected to more severe usage than any casting in any other line of work. In the first place, in the usual single acting engine one end is exposed to the heat of explosion while the other remains cool. The excess heat that must be carried off in order to make lubrication possible may be disposed of either by a water jacket or by air cooling ribs or projections. We will assume that we have an outline of the interior of the cylinder bore and the valve seats. These are the only surfaces that affect the proper working of the cylinder, and they should be perfect and maintained so under working conditions. However, the best that can be done is to make conditions as favorable as possible.

The bore and valve seats must be connected to each other in such a manner that the connecting passages do not affect the surfaces in question, and that the intervening metal does not distort the one or the other or both under working conditions. Among the questions that arise in this connection are the following: How can we keep the temperature the same at all points of the bore? Can any form of water jacket be devised that will evenly cool a single acting cylinder? At what point on the bore should the jacket terminate? Will the point where it does end tend to affect the bore? Can the thickness of metal be varied to properly conduct the excess heat generated? Any possible solution of these problems is only a makeshift at best.

VARIOUS METHODS. The machining of a cylinder is a difficult problem, even with the most careful design. Some claim that they grind the bore, and that that is the only way to get a true bore. Some claim that the casting should be annealed either before machining or after it has been roughed up, and previous to grinding, while others claim to get results by the aging process. There are also some who claim that the only way to finish the bore is by reaming. They claim that the fine particles of emery lodge in the grain of the metal and cause undue cutting of the piston. I doubt if the process can be condemned on that account, but where loose emery is used to lap the cylinder and piston rings to a fit, there is some chance for this trouble to occur. The writer knows of a test made with locomotive slide valves to compare the results of scraping with that of grinding the valve and cylinder faces. On one side of the locomotive the cylinder and valve were scraped in the usual manner by hand, while the surfaces on the other side were fitted by grinding the valve in place with fine emery between the faces. Every precaution was taken to make the experiment a success, as the grinding process was much quicker and cheaper than the old method of scraping. After the locomotive had been put on the road the steam chests were at intervals opened to note

the condition of the two faces. The final result was that a return was made to the old process of scraping, as the cylinder and valve on the side that was ground were decidedly rougher and scored, and it was reasoned that this was due to the particles of emery imbedded in the surfaces, while the valve on the other side had the usual surface obtained by the old process. The above method can only be compared with the lapping process, and it is not intended to show that where grinding is resorted to the results obtained must be bad, for if the surfaces on the locomotive cylinder and slide valve had been finished on a surface grinder the result obtained would have been dif-

#### TEMPERATURE AFFECTS CYLINDER.

Much study has been given to the subject of boring, with the object of improving the quality of the work and increasing the output. I am sure all will agree on the point that where speed is desired and the roughing cuts are forced to the limit, the heat generated by the cutters does disturb the bore somewhat, and if the bore is finished at one setting it will change when the cylinder cools off. That may mean that the cylinder will be more perfect under working conditions than one that has been ground after annealing, aging, etc., have been resorted to.

### ROUGH BORING.

The method in use to rough bore fast and save time with the first cut is to use a stiff bar (slightly smaller than the rough bore, to allow for irregularities and cuttings) into which are inserted a series of cutters I inch or more apart, the entire length of the bar. These cutters are arranged with suitable mechanism to set them out or draw them in. The method of using the bar or roughing tool is to draw in the tools, run the bar into the extreme or head end of the cylinder, then feed the tools out so as to cut grooves in the cylinder bore. If the tools are spaced I inch apart the amount of travel necessary to remove the stock would be just I inch. For instance, if the length of bore were 10 inches and the bar had ten tools I inch apart, the rouhing cut would be completed with I inch of travel, or ten times faster than if a bar with one set of tools traveling to inches were used. The number of cutters spaced around the circumference is, of course, optional. I prefer an even number of cutters, mainly for the reason that this permits of calipering the diameter, which cannot be done with odd numbers. Further, if the number of cutters is the same in all heads, any irregularity with the first rougher will be taken up in the second and third cuts, but if we should use for the first head four tools, the second six and the third eight, the chances are that the one will not mesh with the irregularities of the other, and they will tend to eliminate the defect of the former by absorption of the cut with a cutter having more points out of mesh with each cut, while all can be sized readily. To those who finish by reaming the advantages will be apparent; and to those who finish by grinding the result will be the same.

#### GRINDING VERSUS REAMING.

As to the advantages of grinding over reaming in finishing the bore of a cylinder, there are at least two that are important. First, the cylinder can be given a smoother surface by grinding than by reaming, and less time is required by the former process. The reamed cylinder would have to be "run in" either at the factory or by the owner of the auto. It is also safe to assume that if the original pistons and rings are used the necessary "wearing in" to the point where the engine runs at its best occasions considerable loss of power and expense in overcoming the extra friction. Second, all who have had to do with reamers know that it is next to impossible to keep them to size, especially if the output is great. With the grinding process that difficulty is not encountered, and cylinders can be bored to standard sizes, so there is no need for fitting pistons to cylinders. I have seen it claimed as an advantage of the reamed cylinder that the surface will retain oil better than that of a ground cylinder. That I do not doubt, but I contend that if the bore were finished to a glass hard and smooth finish it would not need as much oil, and would not cut so readily. If the surfaces are smooth grit cannot get a hold.

There is another point regarding the finishing of cylinder bores. If the thickness of metal is not regular the bore will not be regular when hot, whether the bore is finished by one method or the other, cold annealed, seasoned, or according to any other process. The conditions are especially bad in twin cylinders where one cylinder is finished while the other is yet in rough state. En bloc construction makes things still worse, and such cylinders where the exhaust pipes are a part of the cylinders cannot possibly keep straight under working conditions.

### BORING TWO CYCLE CYLINDERS.

The boring of two cycle cylinders is a particularly difficult problem. The ports are usually a source of trouble, and grinding has been suggested as the only way to finish such a cylinder, but anyone who has had the opportunity to make observations will be convinced that grinding does not give perfect results. Where the metal is uniform around the ports better results can be obtained by the reaming process, finishing while the heat of the roughing cuts still affects the bore. It would seem that a cylinder finished by grinding after it has cooled off will develop high spots under working conditions, while one that is reamed while hot will not. At least that has been my experience with two cycle motors, and the same thing will occur with the usual four cycle cylinder, to some extent.

# THE HORSELESS AGE

# Public Speedways Proposed in England.

Sanguine writers on automobile topics have repeatedly in the past suggested the idea of wide, straight, dustless roads built specially for automobiles, on which cars could be driven at any desired speed, but it remained for the British Minister of Finance, Lloyd George, to take the first step to put the idea into effect. He has introduced in the House of Commons a bill which provides essentially for the construction of special exclusive automobile roads or speedways throughout the country.

Perhaps in no country has there been so much friction between motorists and the general public over speeding, dust raising, etc., as in England, if the extensive operation of speed traps and bitter controversies in the press are reliable criteria. It seems that Mr. Lloyd George set himself the task of ending these differences. Realizing, no doubt, that a good deal of the public animosity toward motorists is based on jealousy, he set out by proposing an increased tax on automobiles and a tax on all fuel used in automobiles, except those engaged in public service. As might have been expected, this

bill aroused a storm of protest from motorists and the motor industry, notwithstanding the fact that it was provided that the proceeds of the new taxes should be used for road improvement purposes. This clause, it seems, did not appease the motorists in the least, as it was intended to, and the objections to it have become even more pronounced now that it is known in precisely what way the funds thus to be raised are to be applied.

The majority of automobile users will hardly care for these specially constructed speedways. Automobiles are coming to be used more and more as utility vehicles; that is, for making trips to particular points, instead of simply for enjoying the motion, the open air, etc., and to those who make use of their cars in their regular pursuit the speedways would seldom be available, as it is, of course, inconceivable that these special roads would be built on such an extensive scale as to parallel practically every public road.

It is, no doubt, true that a road built exclusively for self propelled, rubber tired traffic would be built quite differently from the modern macadam road, which latter system of road construction was developed to meet the requirements of horse drawn, steel tired traffic. Automobile roads would probably have less substantial foundations, but smoother, harder or continuous surfaces. As the automobile traffic on roads increases and horse traffic decreases proportionately, the regular roads will, no doubt be provided with surfaces that are better suited to automobile traffic. The enormous sums that would have to be spent for even special main roads for automobiles could much more profitably be invested in the improvement of existing roads, in dust treatment, elimination of hidden turns and grade crossings, grading or proper banking of dangerous curves, etc. We notice that an opposition movement to Mr. Lloyd George's proposal has already been launched in England, and consider it very doubtful whether his plan will meet with much support in Parliament.

# Is the Spare Tire Superfluous?

The necessity for constantly carrying, as a part of the emergency equipment of a car, one or more spare tire shoes is rather an objectionable one.

Not only does this extra equipment often interfere with getting into and out of the car, but casings are not infrequently stolen at times when the car is left unattended.

They also deteriorate to a certain extent in the long period during which they may be carried about, and, of course, add a perceptible weight.

The matter of carrying spare casings has recently been called to mind by the statement made by one of the most conservative American automobile manufacturers to the effect that it is no longer necessary to carry such extra shoes upon his cars.

Upon the cars of this particular make, which are noted for their light weight and effective springing, tires of very much larger section than generally supplied for the same supported weight are provided, and the casings are thus worked at much less than their rated safe carrying capacity. This amounts to the provision of a considerable factor of safety against blowouts.

A growing tendency to equip cars with tires of larger cross sections than those which barely suffice to meet the recommendations of the tire manufacturers has been noted in these columns, and it is an interesting fact that a large proportion of this season's purchasers of several well known makes of medium or low priced cars, embodying 3½ inch tires as regular equipment, have chosen to have their machines fitted with 4 inch tires at extra expense. Not a few such owners have operated their cars successfully during the earlier use of their tires without carrying spare shoes.

Whether tires of extra large section in proportion to their load are fitted, or whether a spare casing is carried, one, of course, pays for the security thus obtained; but it is a question whether a greater degree of security cannot be obtained for the money expended by the former than by the latter course, all things considered. An equipment of tires of extra liberal size is undoubtedly quite an effective form of insurance against delays due to tire troubles, other than punctures, while an equipment of tires rather stinted in size, even though spares are carried, still involves a decidedly greater risk of involuntary stops upon the road.

With the further improvement in tires which may be hoped for, resulting as it will in less frequent premature failures, and with the growth of the use of the blow-out patch as an emergency device, it may well be that the custom of carrying spare casings may safely be discarded, except where touring in remote districts is practiced, and in the case of cars of such weight that tires large

enough to furnish a liberal factor of safety are unobtainable.

## Noiseless Engine Auxiliaries.

In the attainment of noiselessness in the operation of modern cars no details are too small to be overlooked by the careful designer. After every precaution has been taken to remove all preventable sounds emanating from the motor itself, the auxiliaries become objects of attention in this regard.

Recently the circulating pump, when of the gear type, has been subject to improvement in this direction. It has been found that the spur gears used in these pumps lacked quietness, and in several of the most refined designs noiseless herringbone gears have been substituted therefor.

Radiator fans have been found in many instances to contribute substantially to the noise of the power plant, and very careful attention is now paid to the shape of the blades, the running balance thereof and the securing of a high degree of rigidity. Certain shapes of blades set up an altogether unnecessary volume of sound, and, if balance is not looked out for, a noisy vibration results at certain speeds. Rigidity is now secured by ribbing the blades and fastening their tips together by means of a guard ring, which also serves the purpose of making less disastrous an accidental contact with the moving fan.

While much of the noise arising from the auxiliaries has been obviated by the provision of fibre or other non-sonorous gears in their drives, there is sometimes a perceptible sound arising from the flexible coupling commonly used to drive the magneto from the auxiliary shaft, subjected as it is to rapidly recurring fluctuations of torque. Even this seemingly minute source of noise is considered and taken account of in the design of the flexible joints used.

It hardly seems possible, at first thought, that the slight noise arising from the speed-ometer flexible shaft and driving gears should be perceptible among the other sounds incident to the operation of a car, but so nearly silent have modern cars become that the speedometer sounds are often clearly and sometimes objectionably apparent. Among speedometer makers the reduction of these slight sounds has become a matter of substantial importance, and so fastidious have car users become that the quietest speedometer drive has become a distinct desideratum.

 indeed, has been the success atapproximating to noiselessness of operation that should the present type of poppet valve gear be displaced by some rotary type, the automobile might be expected to become an almost absolutely silent vehicle.

# Dealers' and Salesmen's Conventions.

The practice adopted by the larger and better established automobile manufacturers of calling together their salesmen, district managers, agents and repair men, at the home factory, to inspect and receive instructions concerning the new models, is quite common this season. That the custom is an excellent one can hardly be doubted.

The industry has always suffered more or less from a lack of intelligent co-ordination betwen the manufacturing and the selling departments. Agents have too often been less well versed in the details of the construction and characteristic points of the cars which they were handling than the good of the business demanded, and, at the same time, the factory men have not always been in close enough touch with the outside forces to obtain a just idea of the status of their product, from the dealers' standpoint, which reflects very closely the opinion of the general public.

A meeting of the manufacturing and selling forces of a company at the factory not only tends toward a healthy esprit de corps among all concerned but assists in consolidating the entire organization into a more effective instrument for building and vending automobiles acceptable to the public.

Held, as these meetings usually are, very soon after the model cars for the coming business season have been formally adopted, the conditions are very favorable. The visiting agents, dealers and repair shop men can see and note the performance of the new cars, the parts can be observed going through the factory in their various stages, and the engineering and production departments may be trusted to leave no point of the cars unmentioned which a salesman or repair man may profitably know. The selling force is able to report most fully, upon such an occasion, as to the tendencies observable in the buying public, and to call the attention of the factory to any shortcomings or to possible improvements which may be made.

The automobile industry being a comparatively new one its internal organization has not been so far perfected as that of older lines of business, but anything which tends toward a closer and more intelligent understanding and co-operation between the productive and the selling ends leads toward the ability to do business more effectively and economically and with less friction.

### Good Roads Activity.

The second annual good roads convention of the American Automobile Association will be held in Cleveland next week and about a month later the American Road Makers' Association will hold their annual meeting at Columbus, Ohio. There has recently been considerable activity in the organization of good roads interests, and during the coming winter large appropriations will very likely be made by many State legislatures. As roads have to be built with State and county funds, it appears that State organizations can do the most effective work in urging appropriations and arousing public interest in the subject, and it is therefore a matter for congratulation that State roads federations are now being organized. While the Cleveland convention will be held under the auspices of an automobile organization it will be attended by official delegates of many States, and even the National Government will be represented by Director Page, of the Bureau of Public Roads. Besides the motorists, that other great body of road users, the farmers, will also be represented by ex-Governor Bachelder, of New Hampshire, president of the National Grange. The motorists and the motor industry want improved roads badly, and we do not believe that a single voice would be raised among them against appropriations of almost any amount for road building so long as it was fairly certain that the moneys were actually being expended for the purpose in a businesslike way. The farmers also realize that they would be benefited by good roads, but many among them seem to doubt whether the benefits to be derived warrant the cost. If these doubts can be dispelled, and the whole farming community can be enlisted in the cause of good roads, then we believe the construction of roads will be limited no longer by limitations of funds available. but simply by the number of laborers and teams available at reasonable rates.

According to a recent decision of the Minister of Finance of Colombia, South America, bicycles and motor cars are dutable according to the second class of the tariff schedule, without the 70 per cent. tariff majoration.

# Electric Cradle Dynamometer-Method for Test of Gasoline Engines.

(Paper read by H. S. Baldwin before the Chicago Meeting of the Society of Automobile Engineers .- Condensed.)

When the early electric motors were being developed, about 1884-86, it is recorded that the cradle dynamometer was devised by Professor Brackett as a more accurate means for ascertaining the "stray power" factors than the Prony brake, and since this form of dynamometer consisted essentially of a cradle upon which was mounted the electric motor to be tested, there can be little doubt as to the approximate date of its origin.

It should be explained that the early Brackett dynamometer, while embodying the principle of the modern cradle type, differed in that the motor under test was supported bodily in a framework which was free to rock through an angle sufficient to permit measurement of pull at the end of an arm. A leather belt was employed to transmit power from the motor pulley to a line shaft. It will readily be seen that this method would be awkward and impracticable for the test of gasoline engines. The principle was correct, and the only change necessary was to consider the electric motor as a generator to be used for loading the engine, which is connected by means of a flexible coupling to the shaft rather than by a belt.

In designing electrical apparatus there are many comparatively small factors such as brush friction, bearing friction and windage, I2R and iron losses, each of which has to be carefully considered in order to obtain machines of high efficiency. All this called for greater refinement in making power measurements than had before obtained, and the cradle dynamometer was found to have the required nicety. Manufacturers have continued to use the cradle dynamometer, modified and improved, for so called "special tests" in studying the characteristics of new motors and generators.

It may be asked what are the peculiar advantages of this form of dynamometer.

First-All variable factors are entirely eliminated, and it is only necessary to read the pull of the brake arm and note the rotative speed.

Second-Load can be held steadily at any desired point within the limits of the dynamometer, for an indefinite time.

Third-This dynamometer is of the absorption type, but the load is dissipated in a suitable rheostat at any desired distance from the dynamometer, which itself only reaches moderate temperature.

Fourth-The cradle dynamometer can be used to measure transmission losses, friction of bearings or other mechanical parts, and the effect of various lubricants.

Fifth-As applied to the test of gasoline engines it may be used for starting the engine.

Some may consider that a well designed water brake has most of the advantages above set forth, but it is certain that the electrical construction presents the greatest possible simplicity. In this, as in all matters, it will undoubtedly be a case of "survival of the fittest."

Commander Krebs, of the Panhard, & Levassor Company, appears to have been one of the earliest users of the cradle dynamometer for testing gasoline automobile engines, and several members of this society have made use of it for a number of years with success.

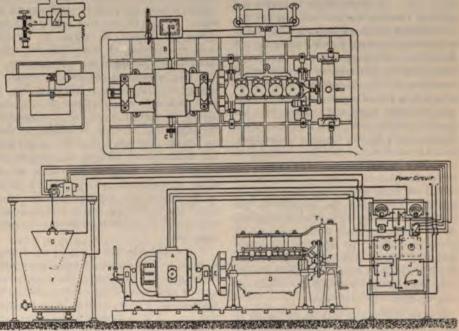

The following is a description of a cradle testing outfit laid out by the writer some three and a half years ago (Figs. 1, 2 and 3) for the test of a four cycle gasoline engine. Excellent records were obtained and a somewhat detailed description may be of interest.

So far as ultimate results are concerned, the generator forming the dynamometer may be suitable for any electric circuit. either alternating or direct. It happened that the line available was of direct current, and it was, therefore, only necessary to choose the type of generator, series, compound or shunt, and whether to use commutating poles or not. The series machine was eliminated owing to the low resistance of its field, requiring high exciting current and consequent loss in cutting down the potential of the line. Again, since it was decided to separately excite the field there was no particular advantage in the compound winding, and its more complicated construction led to the adoption of the shunt type. Here the field resistance is high with low current, or the reverse of conditions

found in the series generator. The onestion of use of the commutating pole generator was considered, but it was decided that it was not required, since the strength of field could be adjusted to the load and speed of engine so as to secure good commutation. There is no objection to commutating poles, except added first cost, and, while experience shows that they are not essential, they undoubtedly tend to better commutation under extreme variation of load. This statement is made as the service conditions of an engine dynamometer may be severe.

The generator chosen was of 20 horse power with six poles shunt wound, and its successful operation over a period of several years proved the correctness of its selection. No difficulty was found in varying load on engine between 5 and 35 b. h. p., and the latter load could be maintained for two hours or more at rated speed of about 1,000 r. p. m. without overheating the dynamometer. For a short period of time it was found that the load could be increased to 40 b. h. p.; also that satisfactory readings could be made at the other extreme of about 5 b. h. p. No attempt was made to reach higher or lower points than these, but if desirable this could undoubtedly be done. Obviously there is no limit to the size of generator, and it may be of small capacity for "stray power" readings of electric motors, or of sufficient capacity for the largest gasoline engines. Care must, therefore, be exercised in the choice of rating of the generator so that it will be suitable for the power range for any particular engine.

The next step was to machine the magnet frame on the outside and adapt the bearing heads to fit large annular ball bearings to carry the weight of the complete machine

ARRANGEMENT OF APPARATUS FOR ELECTRIC CRADLE DYNAMOMETER.

A, electric cradle dynamometer; B, lever arm; C, adjustable counterweight; D, gasoline engine; E, flexible coupling; F, water rheostat; G, movable electrode; H, motor to control movable electrode; I, double pole double throw switch; J, starting rheostat; K, overload circuit breaker; L, ammeter; M, voltmeter; N, double pole double throw switch for reversing H; O, dynamometer field switch; P, dynamometer field rheostat; Ω, platform scales; R, tachometer; S, radiator; T, thermometer pockets.

with minimum of friction. The frame with field coils in place was then given a rough balancing. A brake arm and stud for counterweight were bolted to the frame diametrically opposite, and suitable pedestals were mounted on a base casting so as to receive the ball bearings and support the generator. The counterweight was adjustable radially on the stud which was threaded.

Most cradle dynamometers that have been called to my attention have had brake arms fitted with weights. This method of measuring the pull has the disadvantage of requiring a number of movable parts or an accurately graduated brake arm. Experience not only in engine testing but in the test of electrical appartus has shown that best results are obtained by the use of accurate platform or spring scales, thus doing away with the graduation of the dynamometer beam. It is, of course, of great importance that the knife edge of the brake beam be an exact number of feet from the centre of the generator shaft, and notches can be cut in the arm at points to give, for example, a length of 2, 3 or 4 feet. Three feet was found to be a convenient length to allow space for the platform scales and passageway for tester. A stop was placed on the magnet frame of the generator to limit its tendency to rotate to a small angle only sufficient to operate scales. This stop is necessary also to prevent reversal of the dynamometer in case the engine should back fire. A bracket was provided on one of the pedestals for a tachometer of the liquid type, which gave good results. A belted mechanical tachometer can be used. but in either case it should be carefully calibrated from time to time to insure accuracy, for it must be understood that the only variable factors in the cradle dynamometer are speed and weight of pull of brake arm. Of course there is always the personal factor of the observer, but this can be corrected by the employment of a checker on work requiring extreme accuracy. If desired, a continuous record of speed and torque can be obtained by an instrument consisting of a clockwork mechanism actuating a long roll of paper graduated in minutes, on which speed and torque curves are traced in ink by pens. The pens are moved synchronously by two pressure gauges connected by small metal tubes filled with liquid. one to the tachometer on the dynamometer shaft, the other to a small cylinder at the end of the brake arm. When the dynamometer is in operation the pressure in the two columns causes the needles to trace the curves accurately, since liquid is practically non-compressible. In studying the operation of an engine with varying load conditions this method is of value, but for ordinary work at uniform load the simple direct readings are preferable.

It is sometimes said that the only error of the cradle dynamometer is the windage of the armature, but this is only I to 2 per cent. of the total output of the generator, and can be entirely eliminated by running the re at the desired speed by means of the gasoline engine and adjusting the counterweight so that the brake arm remains level and the scales read zero.

There are many forms of flexible coupling that may be used between the engine and dynamometer, but there must be real flexibility, otherwise the coupling will cause undue friction by lack of alignment and eventually break. The selection of a good coupling is therefore essential, as was found after breaking a number of strong universal joints and the like. The coupling indicated in the diagram (Fig. 1) was free from objection, and in all our tests has stood up well. It is the old interlaced leather belt type, with which undoubtedly all are familiar. It was found desirable to have the larger outer drum mounted on the generator shaft so as not to unduly load the crank shaft of the engine. By so doing the coupling can be made of comparatively large diameter, facilitating adjustment of leather strap. A locking ring should be provided to hold the belt from slipping out of place and the two drums carefully balanced.

A good way to mount the testing outfit is to use an iron plate divided into squares by T slots near the top surface. The plate should be machined at top, sides and ends, and may be embeded in concrete. It is de-

SIDE VIEW OF DYNAMOMETER.

sirable to mold a groove or channel in the cement around the plate to catch any oil or water. A base of this kind will greatly facilitate the testing of engines of various sizes, and permits of many different combinations and arrangements of apparatus.

A very convenient and effective form of support for the engine is shown in Fig. 1. Four pedestals are machined on top and bottom to correct height to accommodate the supporting arms of the engine so that the crank shaft shall correctly align with the dynamometer. These are clamped or bolted to the table and the engine set in place. It will readily be seen that this method permits of the greatest possible space under and around the engine, and is an improvement on the awkward structures sometimes used.

It is suggested that a test of the engine be made to include one of radiator as well. From personal experience this is of much interest and value. The radiator should be mounted in correct relation to the engine and fan. If it is desired to make the test more complete, both engine and generator can be covered by a bonnet and air supplied by a large blower in front of the radiator to simulate road conditions. By using this method the water can be kept at any desired temperature at inlet and discharge of radiator. In most cases it is preferable to pipe the engine to a water main or large tank. Care must be taken, however, not to have the water too cold, and to prevent this there should be thermometer pockets at the cylinder inlet and discharge.

There are several ways to dispose of the output of the dynamometer. Some makers recommend that it be used for charging storage batteries; it is usual, however, to consider this energy a loss and dissipate it in a cast iron or water rheostat.

Our experience is favorable to the so called "water barrel" with movable electrode, and this is the form shown in Fig. 1 at E. The receptacle for water is not really a barrel, but a cast iron tank with flaring sides so that ice will not crack it in winter. The electrode G is made from a plate of boiler iron, and is suspended by a wire cable. It is desirable to insulate the cable from the electrode as shown. The tank is supported on glass insulators, as the circuit is not grounded. A positive wire from the generator should be connected to the movable electrode, as electrolytic action will after a time cause destruction of the plate, which is more cheaply and easily replaced than the tank. A large cock is placed near the bottom to drain off the electrolyte when desired. Clear water is not a good conductor, and it is found necessary to add a certain amount of Glauber's salt or sodium sulphate (Na2 So4) in order to give the right current capacity. A convenient method is to make a saturated solution of this salt and water in a pail and add as required. This procedure prevents the use of an indefinite amount of salt, and will be found to save much time and annoyance. A rheostat, as shown in Fig. 1, which is about 3 foot square on top can absorb about 25 kilowatts. From time to time it is well to run off the solution and clean out the tank with clear water. A water pipe run to the barrel will save much trouble in filling and cleaning.

In the upper left hand corner of Fig. 1 is a small diagram. The double throw double pole switch N is the same as is seen on the switchboard, and is used for reversing the controller motor H, which raises and lowers the electrode G to regulate load. This is a refinement, and is not absolutely necessary, as G can be raised and lowered simply by the cord. It often happens, however, that the rheostat cannot be located near the test, and it then becomes necessary to find some other means for the purpose. An arrangement to this end has been devised consisting of a small motor, which operates a screw by means of a worm and gear having a ratio of reduction of about 1 to 100. There is a safety device so that when the switch is thrown to lift the electrode, for example, the circuit will be opened automatically before any damage is done. Excellent distant control of rheostat is thus obtained without danger of breaking parts or short circuiting the load line.

It must be understood that the apparatus shown on the switchboard is only for the convenience of the operator, to permit variation of load, to start the engine by using the generator as a motor, and for the protection of the dynamometer itself. In other words, after load is adjusted it is not necessary to have a technical attendant to observe the simple readings which show the brake horse power of the engine.

Having the pull of the 3 foot arm of the dynamometer and the revolutions per minute, the well known Prony brake formula can be applied.

B. H. P. = 
$$\frac{2 \pi L P N}{33000}$$

in which L=the length of brake arm in feet; P=the pull at end of arm in pounds, and N=speed of crank shaft in revolutions per minute. Assuming that the arm is to be 3 feet long the formula becomes

B. H. P. = 
$$\frac{2 \times \pi \times 3 \times P \times N}{33000}$$

and combining constants.

B. H. P. =  $0.00057 \times P \times N$ , which is a simple and sufficiently correct formula for ordinary purposes.

Voltages of 115 and 230 direct current have recently been adopted as standard for shop power circuits, and the switchboard equipment can be adapted to either.

In order to be able to start the gasoline engine by dynamometer, the starting box J (Fig. 1) and double pole double throw switch I are wired into the power circuit. If hand cranking is to be used both starting box and switch can be omitted, much simplifying the board. In either event there should be an adjustable overload circuit breaker K to prevent injury to the engine in case of short circuit on the load line.

Again, if some part of the engine "seized," preventing it from starting when using the dynamometer as a motor, the circuit breaker would operate and a burnout would be avoided.

The voltmeter M and the ammeter L are not essential, but are strongly recommended as indicative of conditions in power and load circuits.

The switch N has already been referred to in description of the method for controlling movable electrode. To vary load it is only necessary to momentarily throw reversing switch N up or down to raise or lower electrode G. If hand control of electrode is preferred, motor H and switch N can be eliminated. They will, however, be found of great convenience.

It will readily be seen that the switch O is in the power circuit of the dynamometer field and should be provided with fuses. The rheostats P, P afford regulation of field strength, and for fine gradation of load one should have about ten times the ohmic resistance of the other, with, perhaps, 25 points on each.

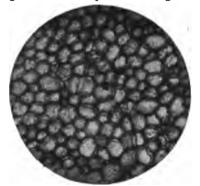

In preparing this description of apparatus for the test of gasoline engines it has been the aim of the writer to set forth somewhat in detail such arrangements as have been

found, by actual experience, to be useful in studying and improving engines, more particularly with relation to the automobile. Those members who already employ the cradle dynamometer method will undoubtedly be able to add much of value to what has been said, and it is hoped that there will be liberal discussion of the subject, which will bring out further points of interest and assistance to the membership in general.

# The Production and Properties of Cork.

The following matter is taken from an interesting pamphlet issued by the Armstrong Cork Company, of Pittsburg, which we received through the kindness of Wheeler & Schebler, who use this material for their carburetor floats. Owing to its rather extensive use for this purpose, and in friction clutches, we believe it to be of some general interest to the trade.

Most of the world's supply of "corkwood" is produced in the countries bordering the Mediterranean Sea. Portugal and Spain are the largest producers, although considerable quantities are grown in

CORK UNDER THE MICROSCOPE.

Algeria, southern France, Tunis, Italy, Sardinia and Sicily. The "corkwood" of commerce is produced from the bark of a species of oak which grows to a height of from 20 to 60 feet, and sometimes attains a diameter of 4 feet. Only the outer bark is used, it being removed very carefully so as not to kill the tree. The first bark is harvested when the tree is about twenty years old, and is of inferior quality and of little commercial value. Some ten years later the tree is stripped again. While the second stripping gives better bark than the first, it is not as good as that furnished by the later strippings, which occur at intervals of about nine years. The best bark is produced after the tree is about forty years old, and it usually continues productive until nearly a hundred years of age, though much older trees are not unknown.

Both the trunk and the larger branches are stripped. The bark ranges from half an inch to 2½ inches in thickness, and a tree may yield 45 to 500 pounds, depending upon its size and age.

As the bark is removed it is gathered in piles and left a few days to dry. Having been weighed, it is carried to the boiling stations, where it is stacked and left to

season for several weeks. The boiling process loosens the woody outer portion of the bark, so that it can be scraped off. It also removes the tannic acid, increases the volume and elasticity of the bark, makes it soft and pliable, and flattens it out for convenient packing.

After being roughly sorted as to quality and thickness, the bark is transported overland on burros, much of it going to Seville, which is the greatest centre of the industry. Here it is sorted into a dozen or more grades, according to quality and thickness. That destined for transportation is packed in bales, which have the grade stencilled on the side.

When these bales are received the corkwood is sorted into some twenty-five grades, which are finally divided into about 150 classes, according to quality and thickness. This sorting is the most particular process in the manufacture of articles from cork, since the success of many articles depends upon the uniformity of the material. After sorting the corkwood is placed in a warm vapor bath to soften it before cutting.

The cutting processes vary considerably with the shape of the article being produced, but they all depend upon the use of a thin knife, kept sharp as a razor, which revolves rapidly while being pressed against the cork. This gives a drawing cut, the microscopic teeth on the edge acting like a saw.

Under the microscope cork shows a most peculiar structure. It is seen to be composed of small sealed air cells, which lie together like roughly round pebbles in a pile. These give it its unusual toughness and resistance to wear; they make it nearly impervious to air, water, oil and similar substances, a non-conductor of heat and a non-absorbent of moisture.

It is used for a great variety of purposes, and the industry is of considerable size, as will be seen from the fact that the annual imports into the United States of crude and manufactured cork reach a value of almost \$5,000,000.

At Frankfort, Germany, about 80,000 square metres of road surface is being tarred this summer in order to combat the dust nuisance.

According to a German consular report there is not much of a market for motorcycles in Chili, as the roads leave much to be desired. The imports of motorcycles during the past year amounted in value to \$59,640, and were mostly of American and German origin. The use of automobiles is limited, owing to the bad roads, the difficulties of getting repairs made, and the unreliability of the drivers obtainable. Owing to the financial crisis the value of imports decreased from \$79,691 in 1907 to \$38,515 in 1908. The principal countries of origin are the United States, France. Germany and England.

# Five Glass Landau Auto Body Design.

By Joseph Ledwinka.

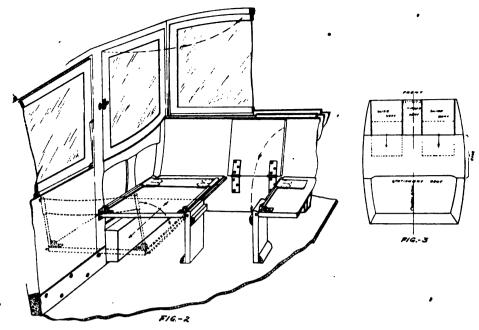

Fig. 1 represents a novel design for a body in which the position of the front seats is optional with the passenger. The outward appearance is similar to that of a standard carriage of stylish and conservative lines. The body is ample in size, and makes a very comfortable vehicle for taxi service.

The pressed steel frame is dropped between the wheels to bring the body lower and make access very easy. The wheels in this particular design are 36 inches, but these, as well as the frame, can be changed within considerable limits.

Both the size and the location of wheels in Fig. 1 are very pleasing to the eye, and in this respect the design appears to be well proportioned. The rear spring construction is much used in carriage building, and is a well tried, practical and flexible arrangement. The front springs are placed as usual in automobile construction.

The front side windows are hinged on specially constructed hinges, which permit the window to be opened inward, folded against the front window and slid down in a casing or pocket within about 12 to 14 inches from the floor. The front window slides down also, as usual in these windows. So do the door windows, leaving the body open all around the front seat. If the rear leather top is folded down the whole upper portion of the body is open, leaving only the front canopy on the four stationary posts.

Coming to the seats we find a very novel arrangement. The perspective view, Fig. 2, shows the arrangement. The front seat is divided into three parts, of which the centre part is about 12 inches wide, and is hinged with strap hinges to the back of the front seat. The two side seats are set into slides, permitting same to be slid

toward the middle of the doors. On the upper side of these sliding seats are hinged back rests, which can be turned up and form a comfortable back.

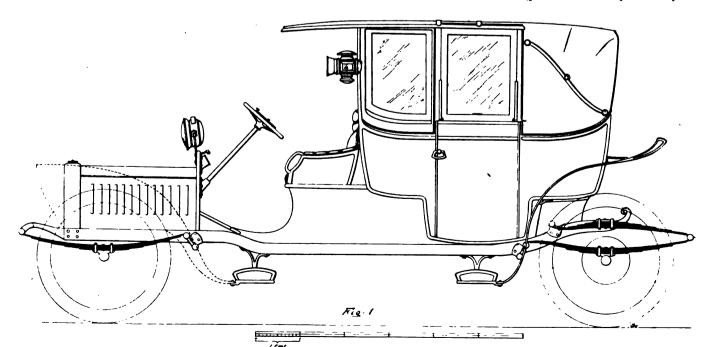

In sliding these seats toward the doors foot room is created in front of them, and the passenger can sit very comfortably, facing the direction of the car. The foot room extends underneath the window casing or pocket, giving ample room. Should the passengers desire to face each other the two slide seats may be pushed forward, the hinged back rest folded down, and the small centre seat folded down, which will give a solid seat all the way across. The middle or hinged seat is upholstered on both sides to match the surrounding upholstery. The two side seats are provided with two loose cushions.

This arrangement is inexpensive to build, and would be very much appreciated by the public.

Fig. 3 shows another view of the seat arrangement. The dotted lines show the position of the seats when facing in the direction of the car.

# New Cushion Tire to Be Manufactured in Columbus, Ohio.

The Cleveland Puncture Proof Tire Company, recently incorporated by Columbus, Ohio, men with a capital of \$20,000, has opened an office at 1355 North High street. The concern holds patents on a tire, the invention of an Akron rubber expert, which is claimed to be better than the ordinary pneumatic tire. At present they are manufactured at Akron, but it is expected to start a plant in Columbus. Robert S. Knepper is president of the concern. The tire is of solid rubber with an air hole of about an inch diameter in the centre, with a slit extending toward the rim, which it is claimed gives the necessary resiliency.

# NEW VEHICLES AND PARTS ➤ ➤

# Maxwell Four Cylinder, Thirty Horse Power 1910 Cars.

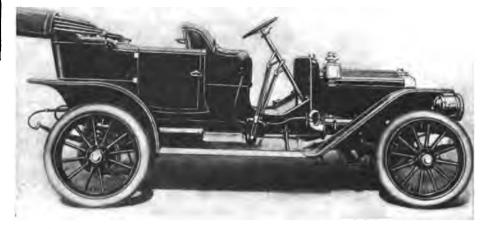

The new four cylinder, 30 horse power models of the Maxwell line for 1910 follow in most particulars the construction of the same cars a year ago, although a number of important modifications and refinements have been made in their design. The most obvious changes are a longer wheel base, larger wheels, roomier bodies and a marked improvement in riding qualities attained by the use of three-quarter elliptic springs. The frame is of pressed steel, hot riveted, and of channel section.

The power plant is of the four cylinder, vertical type, with cylinders cast separately, so that five large bearings can be used. Easy access to connecting rods, main bearings, etc., is insured by large hand holes, four on each side. The valve chambers and water jackets are integral with the cylinders. The water spaces are very large, and extend not only around the piston chamber but also around the valve chambers. The valves themselves are of generous size, located on opposite sides, and operated by cams and square push rods moving in bronze guides.

The crank case forms a unit with the transmission case, and is a special aluminum alloy castings, divided into four compartments which hold a quantity of oil for lubricating the main bearings and connecting rod bearings by splash. The crank shaft is drop forged of nickel steel, finished all over, and treated by a special toughening process. The main bearings are of specially compressed babbitt metal. Particular attention has been given to the connecting rods and their bearings. The rods were especially designed to allow adjustment at both ends, and have oil grooves to insure perfect lubrication.

No change has been made in the change gear, which, as in former cars, is of the progressive sliding gear type, with three forward speeds and reverse. A noteworthy feature of all Maxwell cars is the provision of an interlocking device, consisting of a notched quadrant, which makes it impossible for the operator to shift gears while the clutch is in engagement. The high speed drive is direct from the engine shaft, without intervening gears. The gears are made of chrome-nickel steel of ample proportions. The motor and change gear are supported on the frame at three points. This three point suspension has been a Maxwell feature since 1903. The advantage of the unit construction of power plant and transmission housing lies in the fact that the distortions to which the frame is unavoidably subjected leave the engine bearings and transmission bearings in perfect alignment.

The clutch is of the well known Max-

MAXWELL MODEL E, FOUR CYLINDER, THIRTY HORSE POWER TOURING CAR.

well multiple disc type, and the saw steel discs revolve in a compartment filled with oil. This arrangement reduces wear to an almost negligible quantity, it is claimed. The oil in the clutch compartment is said to also perform the peculiar function of facilitating the action of the clutch in engagement, and this is explained in the following manner: While the oil lubricates the clutch with the plates sliding loosely upon one another, the cohesive property of the thin film of oil that remains between the plates after the surplus has been squeezed out causes the clutch plates to be locked firmly and to rotate together without slipping when the clutch is engaged. Yet the clutch can be made to slip to any desired degree without heating, it is claimed.

The drive to the wheels is by propeller shaft, with two universal joints. The forward universal joint is packed in grease while the one at the rear end of the shafts is provided with a unique self oiling device which is claimed to obviate all wear. The engine is inclined so that a straight line may be drawn through the engine shaft and continued through the transmission and drive shafts through the differential. This straight line drive reduces wear in the universal joints to a minimum besides saving engine power.

Cooling is by the thermo-siphon system, of which the Maxwell was an early exponent. This method of engine cooling requires no pump. The cooling effect is proprotionate to the requirements of the engine. The action of the honeycomb radiator is assisted by a belt driven fan.

The carburetor is of Maxwell design, of the constant level, float feed type, and provided with means for automatic compensation.

The engine is lubricated by means of a pump designed by J. D. Maxwell. This pump forces the oil in exact quantities through a single sight feed into each cylinder. The lubricator is driven by a double set of gears and is positive in its action. Rather novel is the manner in which efficient lubrication of the pistons is insured. The cylinder bears at its base a grooved

ring, which is kept filled with oil at all times and into which the piston dips at the end of each downward stroke. The piston itself is provided with two grooves. The lower groove is filled with lubricant every time the piston dips into the oil ring on the downward stroke and carries oil in an even film all over the cylinder wall. The overflow from the oil rings goes into the crank case and there augments splash lubrication.

Ignition is by magneto with non-vibrating coil, a battery of dry cells being added to facilitate starting. The coil is carried in a steel cylinder under the floor board so that the dash is unencumbered with accessories, and shows only the two-way switch, a single sight feed and glass gauge indicating the level of the lubricant in the tank, which latter also is carried under the hood.

Gas control is double, by pedal and by lever located at the left immediately under the steering wheel. Spark control is by a similar lever under the wheel, located on the right side. The steering wheel is large, and the steering itself is accomplished by worm and sector.

The rear axle is of substantial construction, and equipped with four roller bearings, two on either side of the differential and two near the hubs. The drive pinion also is equipped with two improved roller bearings. Two sets of brakes of the external contracting and internal expanding type are mounted on the rear hubs.

The wheel base has been lengthed to 110 inches, which is still quite reasonable.

The wheels are of artillery pattern, of selected second growth hickory. Their diameter is 34 inches, and the rims are of the quick detachable pattern, with 4 inch tires in front and rear.

All Maxwell bodies are made of sheet steel with stamped moldings, a construction as light as wood and stronger than aluminum, not liable to breakage, since dents may be hammered out, while in the case of the broken wood body the substitution of an entire new panel becomes necessary. The 30 horse power Maxwell chassis is furnished with three styles of body, viz., the Model E, five passenger

and change them fully as frequently as is advisable.

Perhaps the growth of the business around Boston is largely due to the activity of the agents for one make of truck, who have seen the possibilities of the business and have had the courage of their convictions. This concern formerly was and still is in the manufacture of carriages and wagons, and its members enjoy a wide acquaintance among the express companies in the vicinity. They were able to see what

was wanted, and when the machine came along that they thought was right for their customers they did not hesitate to secure the agency for it and recommend it. Then, after having sold the truck they placed themselves in such a position as to keep their customers satisfied, doing repairs and furnishing replacements promptly, and making moderate charges. The result has been that this firm has almost a monopoly of this line of business in the vicinity of Boston.

# Self Regulating Dynamos for Auto Lighting and Ignition.

BY ALBERT L. CLOUGH.

Now that electric lights have come to be so largely used upon motor cars, there is a decided tendency toward the installation of small direct current dynamos for the purpose of continuously recharging the accumulators required to feed the lamps and sometimes frequently to operate the ignition system as well. A generator delivering a nearly constant voltage, independent of the very wide speed fluctuations of the gasoline motor which drives it, is necessarily required. The centrifugally actuated flyball governor, controlling a friction clutch pulley? has been largely used to maintain the generator speed constant, despite the fluctuations of speed of the car motor, and there has also been slightly used an automatic field rheostat, so arranged as to weaken the generator field current in proportion to the increase of speed and vice versa. In order to accomplish this a centrifugal governor is so arranged as to cut into or out of the field circuit a series of resistances when the speed rises or falls. When this arrangement is correctly proportioned the increase in voltage which would be occasioned by a certain increase of speed may be very nearly counterbalanced by the decrease in voltage occasioned by the weakening of the field, which is brought about by the resistance automatically added to the field circuit by the centrifugal governor's movement, due to the rise of speed, and the e. m. f. delivered is thus kept reasonably constant.

It is not unlikely, however, that automatic mechanical devices, such as these, which involve moving and wearing parts and a certain degree of complication, may ultimately be superseded by regulating tendencies inherent in the generators themselves, and due to special features of design.

Inherent regulation of a direct current generator may be favored to a considerable extent by a proper proportioning of copper and iron in armature and field, and by properly predetermining the degree of saturation of the iron, but in the production of a constant voltage, variable speed generator, advantage is sometimes taken of the phenomena of armature reaction. This is done in the case of one small shunt wound bipolar machine designed for vehicle lighting. The neiple involved is crudely illustrated in

e accompanying diagram, Fig. 1.

AUXILIARY BRUSHES.

Two sets of brushes are used, of which ab is the main pair. These bear upon the commutator in the usual position for nearly sparkless operation, that is, at or near the neutral points. Brushes cd are an auxiliary pair which touch the commutator on a diameter nearly at right angles to the main brushes. They are, however, not exactly upon this diameter, but are displaced appreciably in the direction of rotation of the

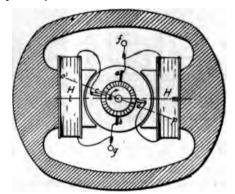

FIG. 1.—INHERENT DYNAMO REGULATION OF VARIED SPEED.

armature. The shunt field circuit is as follows: From one of the main brush leads, near f, it goes through one of the field spools H, and thence to auxiliary brush d, through the armature windings to the other auxiliary brush c, thence through the other field spool H, and finally connects to the other main brush lead near the service binding post g. The auxiliary brushes thus bridge between the two field spools. If c and d were set exactly upon a line at right angles to the line joining the neutral points, at or near which the usual brushes of a bipolar machine are set, there would be no effective voltage acting between them, for the voltage generated in the upper half of the armature would exactly counterbalance that generated in the lower half. If the auxiliary brushes are placed on one side of this perpendicular to the neutral axis, a voltage in a certain direction acts between them, the amount of which depends upon the angle of displacement, and if these brushes are set upon the opposite side of this line the voltage between them acts in the other direction.

The armature and field of this machine are so proportioned that there is a very strong armature reaction; that is, as the current builds up in the armature the magnetic field, which it produces as it circulates in the armature conductors, tends very strongly to shift the field due to the field magnets, with the result that the neutral axis tends to rotate in the direction of rotation of the armature.

PRINCIPLE OF REGULATION.

At very low speeds, when the tendency is for the armature current to be low, the auxiliary brushes have a lead in advance of the line perpendicular to the neutral axes lm, and a certain voltage acts between them. The connections of the auxiliary brushes to the field circuit are so poled as to cause this voltage to act in the same direction as the main field exciting voltage, and thus to assist in energizing the fields. The result is that when the armature is turning at very low speed the field excitation is very much greater than it would be if the auxiliary brushes were not used, and the voltage very much nearer the desired value.

As the armature speeds up there is a tendency for its current to increase, and increased armature reaction results. At a certain point of speed increase, the line 1 m has rotated until it passes through the brushes cd. Under these conditions no voltage is acting between c and d, and they have no effect upon the excitation, the generator operating on simple shunt excitation. As the speed is still further augmented, and the armature current tends to increase to a higher value, the neutral axis is still further rotated and line lm assumes a position such as op. Now there is again an effective voltage between brushes c and d, but, as previously indicated, it is in the opposite direction from previously, and now tends to oppose the regular shunt excitation. Despite the high speed, the reduction in field strength is sufficient to hold down the working voltage to a very much lower value than it would have if the auxiliary excitation were not provided. The higher the speed the greater the shifting of line op in the direction of rotation, the greater the opposing voltage between c and d, and the greater the weakening of the effective field. By a proper setting of the lead of brushes c and d the regulating effect can be increased or decreased, and quite wide variations in speed can be very nearly overcome.

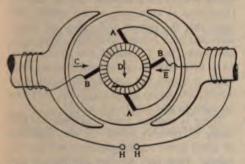

If the evil effects of sparking at the main brushes can be minimized, this arrangement should be of value, as it effects regulation without moving parts, and can always be depended upon so far as it goes.

ANOTHER METHOD OF REGULATION.

Another method of regulation, which has been evolved to secure a constant current through a constant resistance, at widely variable speeds, will here be described, in principle (Fig. 2). This also depends upon armature reaction. To secure the desired results an armature of large iron content and rather heavily wound is used, and the field magnets are of quite small iron section, but

heavily wound with series coils so that they are saturated readily. The pole pieces, on the contrary, are massive and embrace a large polar arc. The brushes AA, which are set as are the main brushes of an ordinary bipolar generator, are here the auxiliary brushes, and are connected together, thus short circuiting through them the armature winding. Brushes BB, which are set on a diameter nearly at right angles to brushes AA, become in this generator the service brushes, and furnish the working current to binding posts HH, through the series fields.

The condition of the magnetic circuit is somewhat more involved than in an ordinary generator. The field coils set up a flux in the ordinary direction from pole piece to pole piece in the direction denoted by the arrow C. This is cut by the armature conductors, which are short circuited by the brushes A A, and currents circulate in the two halves of the armature winding exactly as they do in the armature of an ordinary generator, and produce a cross magnetic flux corresponding to the cross magnetization due to ordinary armature reaction. As the volume of the short circuited current is large, and as the pole pieces are

INHERENT REGULATION FOR VARIABLE SPEED.

very susceptible to it, the cross magnetic flux in the direction of arrow D becomes a very important factor compared with what it is in a machine of usual construction.

The armature conductors in their rotation cut this cross flux D, and a current is induced in them, which is taken off by the working brushes BB to the fields and the external circuit. This current, flowing through the upper and lower halves of the winding, tends also to magnetize the armature core and the pole pieces, and the direction of this flux is along arrow E. That is, this field, which is produced by the armature reaction of the working current, directly opposes the field due to the field magnets. This brings about a very unstable condition of the effective field, which gives rise to the working current. Remembering that the field magnets are of very small cross section, and heavily wound, it is plain that they reach nearly their full saturation before the normal output is attained. The pole pieces and armature core being massive, these parts are at a low density, and an increase of current in the field coils has little influence upon them. Changes of current in the armature acts, however, very powerfully upon these parts at their relatively low degree of saturation.

If the machine is working normally and is suddenly speeded up, the cross field due to the currents short circuited by brushes A A increases, and there is a tendency for the armature conductors cutting this field and furnishing current to the working circuit to increase. Upon such a slight increase occurring, its armature reaction along arrow E instantly increases, and the resulting flux tends to counteract and reduce the field magnet flux C, which latter, being diminished, causes a diminution in flux D, and a lessening of the current produced by it in the working circuit. The rise of current in the working circuit is thus limited to a very small value,

A diminution in speed produces actions opposite to those above described,

On account of the small mass of iron in the fields and the large number of field turns, the machine "builds up" to a working condition at quite low speeds.

By shunting a portion of the working current away from the field coils, regulation to varying current strengths can be attained.

# Methods of Providing Against Torque Reaction.

BY F. E. WATTS.

In all shaft driven cars there is a tendency, when starting forward from rest, for the rear axle housing and propeller shaft to turn backward. When the hub brakes are applied while the car is moving their reaction tends to turn the axle casing forward. These "torque reactions," as they are commonly called, must be resisted by some member or members fastened to the axle in a sufficiently rigid manner to prevent it from turning out of its usual position more than a limited amount.

Three methods of taking this torque reaction are at present in vogue. Where only one universal joint is used the propeller shaft is commonly enclosed in a tube, and this tube takes the torque. The forward end of the tube is usually fitted with some kind of a universal joint arrangement which secures it to the frame. Thus the torque is transmitted from the rear axle directly to the frame. When the brakes are suddenly applied or the clutch is thrown in abruptly the torque reaction rises to its highest value. It is then imperative that the torsion member be very strong or have some provision for yielding slightly under an excessive stress. In the construction just described the tube must be made strong enough so that it is too rigid to yield any perceptible amount. The only way in which deflection can take place therefore is by compression of the springs in the case of brake application, and by the lifting of the car and passenger weight when the clutch is thrown in.

SPRINGS AS TORQUE MEMBERS.

This method of taking torque reaction is quite generally used in the smaller cars, but when the motor is much over 30 horse power the stresses become so great that most designers prefer to adopt some other construction. In quite a few of the smaller cars the torque tube ends just at the rear of the universal joint, and a ball or roller bearing is placed at this point. The torque reaction is then carried by the universal joint. While this construction would seem to be more faulty than the last, from a theoretical standpoint at least it appears to give good service in practice.

For the more powerful class of machines two universal joints are commonly used. The joints are ordinarily enclosed, but the connecting shaft is left bare. A separate torsion member is provided. This has quite commonly consisted of a tube with a ball joint at its forward end, the socket for this ball being secured to a cross member of the frame. The socket is commonly carried in a tubular case between helical springs, so that no matter in which direction the stress comes one of these springs deflects and prevents excessive stresses in the torsion member and transmission parts.

PRESSED STEEL TORSION MEMBERS.

The present tendency is to use torsion members of pressed steel rather than tubular ones. They are usually made of narrow channel section with lattice web, very deep at the rear end and tapering to the end which joins the frame. Sometimes the torsion member is made from two tubes with their rear ends attached to the top and bottom of the driving gear housing respectively, and their front ends joined so that they form a V. Either of these last two constructions gives a light and strong torsion member, but their front ends must be spring supported, as when a single tube is used.

The third method of taking torque reaction is the simplest, and may be the best for certain classes of cars. It consists in making the springs fast to the axle and also to the frame, and letting them take care of the torque reaction as well as the spring support. The propeller shaft is, of course, fitted with two universal joints. Where this is done there must be a very perceptible deflection of the springs when the brake or the clutch is suddenly applied, and this deflection must greatly reduce the maximum stresses in the transmission parts,

While this construction has been used by only a few makers in this country and abroad, they are representative concerns whose practice it is well to watch. It is being used with apparent success on some very powerful cars, and it would seem to permit of a lighter car for a given maximum stress in the transmitting parts than any other construction. It will be interesting to observe whether the circle of adherents of this construction increases.

We would be glad to have any of our readers give their experiences as to the relative amount of wear in the universal joints with different types of construction.

The seventh annual automobile show in Turin, Italy, is to be held April 3 to 24, 1910. The show will again be held in the Valentino Park, and will comprise a motoragricultural and an aerial section.

# Annual Depreciation of Cars.

Editor Horseless Age:

I was much interested in taking up The Horseless Age of September 1 to see that it contained an article by Mr. Clough on the "Economics of Motoring," a subject in which automobile owners are vitally interested. Occasionally some outdoor life magazine has published a carelessly thought out article on the cost of motoring, but to date I have seen little in our papers about the cost of motoring that was not misleading.

I always look forward to reading Mr. Clough's thoughtful articles, but this time I was somewhat disappointed, as he does not base his findings on real experiences (and he must have a great fund of that sort of information), but rather on the empirical assumption that the all important item of depreciation in using a car can be based on an accurately determined seasonal depreciation in the selling value of the car. That would today be a misleading assumption for us all—the manufacturer, the owner and the dealer-though there are, of course, some dealers who have agreed on a fixed exchange value which they will allow for cars of a certain vintage when exchanged for newer ones.

The manufacturer of cars would, I am sure, no longer agree with Mr. Clough that "the decrease in value of the car or depreciation \* \* \* is mainly a matter of elapsed time alone, but which is somewhat dependent upon the extent and manner of use of car," for the great stress laid in all automobile advertisements on wearing qualities shows what the public wants and what the manufacturer claims to give.

The automobile owner, now that the annual improvement in each succeeding model is slight, expects to use the same car for several seasons. He is in consequence less interested in the exchange value of his car with the dealer at the end of one season. but he does want to know how much he has reduced the total possible mileage of the car by the season's running. We used to look at the teeth of a horse to find out how many years of life were left; we look at the teeth in an automobile to see how many miles it will still run. The question of mileage life is the all important one to the owner, whether he runs an imported limousine, a taxicab or a motor truck.

Why doesn't the automobile community come out and face the question of costs squarely? In the end it would be beneficial to all concerned, as it would teach the value of lasting qualities, of good workmanship, of careful use, of economical buying of supplies. Any figures based on experience could only be approximate, but "bey would be helpful. What I am appeal-

ing for, from Mr. Clough's able pen, is an article showing what we common, everyday car owners can expect of a car when in ordinary use by the average user. It is the duty of a technical paper like yours to tell us that a touring car in an economy test can go 42 miles on a gallon of gasoline, but what is much more to the point in my case is that the sort of driving that I, and my chauffeur, and my friends who have similar cars, do, produces about 11 miles to a gallon. I know that it costs me three-quarters of a cent a mile for grease, oil, etc., and that my tires, though they vary greatly as individuals, average consistently above 4.300 miles, but I do not know what my machinery and running gear is costing me per mile, and yet that is the most important and largest item in the operating column. You see I know perfectly well what my fixed charges are, but I have not the necessary information on operating charges that would enable me to decide a simple question of everyday occurrence like the following: Which is the most economical way for me to get my mail twice a day from the post office 3 miles away: send my chauffeur in the imported touring 'car; go myself for it in my American \$4,000 runabout, or pay a youth \$30 a month to ride it up on a bicycle?

Now, Mr. Editor, please let us hear from the manufacturer and from the owner about the life of their cars, expressed not in terms of Glidden Tour trophies, and sealed bonnet contests, or chauffeurs' prizes for minimum first year repairs, but told in words of one syllable for the simple and trusting "average" driver.

A READER.

# Professional Chauffeurs' Badges. Editor Horseless Age:

As a regular reader may I ask you to favor me with the following information:

How many States furnish and compel the wearing of badges by professional chauffeurs, and which States are they? Do you personally think it a necessity?

ARTHUR CUNDY.

[Badges are at present being required to be worn by professional chauffeurs in twelve States, viz., California, Illinois, Michigan, Maryland, Massachusetts, Missouri, Minnesota, New York, Ohio, Pennsylvania, Utah and Vermont.

The requirement undoubtedly acts to protect the State and also licensed chauffeurs.

—Ep.1

## A Case of Missing.

Editor Horseless Age:

I have a car with a four cylinder engine, with make and break ignition and a double jet carburetor. The small jet is controlled by the throttle lever on the steering wheel. The nozzle has a fixed opening, and the mixture is varied by means of a revolving sleeve which uncovers a series of holes bored in the base. The large jet also has a fixed opening, and is similar to the small one, except that it has an auxiliary air valve.

Using the small jet the engine misses badly. I am even unable to adjust the carburetor so the engine will not miss with the car standing on the floor. It not only misses but with some throttle openings runs on three cylinders. I am unable to detect whether this is due to cutting out of any particular cylinders, because each cylinder runs beautifully alone. Any two will also run without skipping, but when the four are put in the engine misses again.

I have owned three cars of the same make as this, and practically the same engine, and all have run fine, so it cannot be the design of the engine or the carburetor. A peculiar thing is that the adjustment of the sleeve seems to make very little difference in the running of the engine, though the engine seems to run better with the leanest mixtures I can give it. Previous engines would vary greatly in speed, and even quit when this sleeve was moved even slightly.

On the road when the slightest grade is encountered, or when the engine is working while picking up on the high gear, all four cylinders explode all right; but when a slight down grade is encountered, say 1 or 2 per cent., the car seems to overrun the engine, and the latter generally runs on two cylinders. The timing of the ignition and the valves is perfect. The compression is good, and there are no leaks in the inlet pipes. The float mechanism seems to be O. K., because the car runs all right on the big jet.

Missing.

[You do not say whether the engine worked as described right from the time it was delivered by the factory or whether the faulty action developed later. If the motor originally ran well on the small nozzle it is, of course, a sign that some of the adjustments have been disturbed, or that there is an obstruction or a leak somewhere in the fuel system. If the motor always ran faultily it may be concluded that the nozzle is not of the proper size to give a correct mixture. The two nozzles with their surrounding spray chambers usually constitute separate carburetors. The small nozzle works (alone) only when the engine is throttled, in which case there is particular chance for the mixture to be disturbed by air leakage. We would advise you to look carefully for air leaks between the carburetor and the motor. Also whether it is not possible for the supplementary air valve to open and admit some air when the small nozzle is working. This might be rendered possible by a poorly fitting valve, for instance.

The small carburetor, of course, furnishes either too lean or too rich a mixture, and it would be well to find out first of all which of the two it is. You say that you get the best results when you adjust the carburetor for lean mixture, which would indicate that usually it is too rich. This conclusion is borne out by your further statement that the engine will work regularly when pulling fairly hard, but will miss when running without load, as in such

a case it would speed up and the richness of the mixture would tend to increase. If the mixture is actually too rich the exhaust should contain black smoke. A lean mixture is characterized by a tendency to tackfire in the carburetor.

If the mixture is found to be too rich this may be due to too high a level in the float chamber, owing to puncturing of the float or leakage of the float valve, too large a size of nozzle, or partial obstruction of the air mlet below the nozzle, tending to increase the suction on the nozzle.—Ep.]

# Starting Six Cylinder Motors.

Lditor Horseless Age:

Your discussion of the subject of starting six cylinder motors on compressed air has started me thinking, and I offer the following suggestions on the subject:

It would be possible to start on compressed air in the manner mentioned if the pressure of the compressed air were high enough to not only overcome the work necessary to compress the gas in the cylinders, but in addition to store enough energy in the flywheel to run the engine idle for a few revolutions, to allow the engine to get its regular working mixture in the cylinders after compressed air had been shut off

A better way would be to supply a mixture of gasoline vapor and air in compressed form to drive the motor. If the mixture were of correct proportions the explosions would take place as soon as the engine had made one revolution. The carburetor passage could then be opened, and the engine would run normally.

A gate valve might be used in the carburetor passage, thereby dispensing with the disadvantages of a check valve.

On account of the complication and space taken up by tank, pump, etc., I do not think it would be good practice for automobile work. It might, however, be used for large stationary or marine motors.

F. CHARAVAY.

The exhibition of speed indicators in Berne, which was organized at the instance of the Swiss Department of the Interior, with the object of securing a useful model for compulsory introduction on all automobiles driven in Switzerland, is being participated in by twenty-one manufacturers. The committee of experts appointed by the Government at its first meeting rejected thirteen models as unsuitable. The other eight were retained, and will be tested in practical use on automobiles. The trials will begin toward the end of this month.

An automobile line is soon to be established between Carlsbad and Monument, N. M. A road is now being built, and as soon as it is completed a number of 60 horse power cars will be placed in service. Several months ago a service was established between Carlsbad, Knowles, Seminole and Midland, N. M.

# Indianapolis to Produce 20,000 Cars Next Year.

It is reported that all Indianapolis manufacturers expect to increase their 1910 output over this year's production. A conservative estimate has it that 20,000 cars will be manufactured in that city next season, one company planning to build 6,000 cars, while another company will manufacture 5,000 cars.

Practically all of the manufacturers have decided to adopt one or two styles of chassis upon which a variety of bodies will be offered; those who have been making four cylinder cars to limit themselves to one four cylinder chassis, and those who have been making both four and six cylinder chassis, to make one chassis of each type. However, one company will make a four cylinder and two six cylinder chassis types.

The Indianapolis agencies state that the sales so far this year have exceeded those of all of last year. One company has sold 750 cars this season, while all of the others have disposed of their original 1909 allotments. Between January 1 and September 10 there were 4,887 automobiles and motorcycles registered with the Indiana Secretary of State.

# May Withdraw from Ohio A. A.

A movement is on foot among the members of the Columbus (Ohio) A. C. to withdraw from the Ohio Automobile Association and ally itself with the Automobile Club of America. The movement started with the refusal of the State organization to participate in the expenses caused by the litigation to have the municipal licensing of motor cars in Ohio declared unconstitutional. Since the decision reached after expensive litigation was beneficial to every autoist in the State, it was thought the State association should help to stand the expenses. A meeting will be called soon to take action on the matter.

## St. Louis Dealers Elect Officers.

The St. Louis Automobile Dealers' and Manufacturers' Association held its first meeting since its recent incorporation at the Glen Echo on August 31. The constitution and bylaws, drawn up by a committee, were adopted, and the following officers were elected: H. B. Kenning, president; Chas. E. Michel, vice president; Sam Breadon, treasurer, and Robert E. Lee, secretary. Mr. Kenning is president of the Dorris Motor Car Company; Mr. Michel is connected with the Union Electric Light and Power Company, and Mr. Breadon with the Western Automobile Company. Messrs. Breadon and Lee were re-elected, having held their respective positions since the association was founded. After the adjournment of the general meeting the board of directors held a special meeting to consider ways and means for securing fairer automobile regulations for St. Louis. Secretary Lee was

instructed to secure copies of the automobile ordinances in force in other large cities of the country, and it was decided to invite Mayor Kreismann to a meeting to be held in the near future, at which the question of regulations is to be discussed. The meeting was well attended.

#### The Lowell Stock Chassis Race.

The final event of the Mergimac Valley automobile carnival took place on Wednesday of last week, and consisted of a race for the heaviest class of stock cars over a distance of 318 miles over the Lowell circuit. The race was won by George Robertson, driving a Simplex car, in 5:52:01 2-5. Second place was secured by A. J. Poole, driving an Isotta-Fraschini, in 6:13:37 1-5, and third place by E. H. Parker, driving a Fiat, in 6:22:21 2-5. The course was guarded by soldiers, and no serious accidents occurred. This being the chief event of the week, and the weather being fine, an enormous crowd turned out to see the race.

## Indianapolis to Have a City Garage.

William A. Rhodes, chairman of the finance committee of the Indianapolis City Council, has recommended that the city establish a municipal garage for the cars that are used by the various city departments. At the present time the city has eleven automobiles in service, and is spending about \$5,000 a year for their maintenance. New cars are to be purchased soon for the use of the city dairy inspectors, and also for the city license inspector. Mr. Rhodes believes that if the city had its own garage, with its own mechanics, it would save money, and at the same time get more satisfactory service.

# Farmers' Insurance Companies to Enter Auto Field.

Farmers' mutual insurance companies of Indiana are taking up the question of insuring automobiles and gasoline engines, and some opposition is resulting among the stockholders of certain companies. One of the leading companies of the kind, the Farmers' Mutual Insurance Company of Montgomery and Fountain counties, has the question under discussion, and probably will decide to insure the automobiles of its members.

## French Exports.

The French exports of automobiles during the first six months of the current year aggregated in value 73,607,000 francs, an increase of 6,842,000 francs over the figure for the same period last year, but a decline of about 4,000,000 francs as compared with the same period in 1907. The imports of foreign automobiles into France again show a slight decline. The aggregate value for the six months was 3,752,000 francs, as compared with 3,774,000 and 4,530,000 francs during the corresponding periods of 1908 and 1907 respectively.

# Commercial Applications.

# Taxicabs in Baltimore. By L. M. WARFIELD.

Baltimore, with rough streets and plenty of hills, is one of the hardest cities of the country on taxicabs. That they have been made to pay, and that the company is encouraged by its success in educating residents to use the service is greatly to the credit of those who inaugurated the service in the city.

Perhaps the worst obstacle was the fact that Baltimore has never had a real cab service. Even the Pennsylvania Railroad, for some unexplained reason, neglected to install a service of horse cabs, and while there were a few vehicles owned by their drivers on call at the stations, the service was generally poor and not popular. The taxi service, however, is astonishingly cheap to those who paid horse rates, based for years on the old boundaries of the city, and therefore decidedly high.

The Taxicab Company of Baltimore, with one garage and a system of calls at the hotels, is operating twelve cars, which make an average mileage of 85 miles a car daily. Each car is on duty practically every hour of the twenty-four. Five more machines were due for delivery when the writer obtained this information, and if the business picks up, as it has recently, others will be added from time to time.

The present equipment includes five Fords, five Autocars, one Atlas and one Stevens-Duryea. The Fords will be replaced with Autocars very soon, as the order for these machines has been given, and they are expected shortly. The Autocars are equipped for four passengers, and are considerably larger and heavier than the others.

The company began rather quietly, and at first relied on calls to its garage, Eager street, between Charles and Cathedral, about as central a location as could be secured. As the service became known it was found profitable to put cabs on calls at different hotels, and now a cab is on call always at each of the larger hostelries of the city. At Union and Camden stations two cabs are kept on duty. A telephone call service to stands is being talked of. In addition, drivers on night duty are allowed to go searching, and this business is found very profitable, especially downtown late at night or in the early morning.

The cabs are equipped with the tires placed by the makers, and so far no agreement with tire manufacturers has been entered into. Very little trouble of this kind has been experienced while cars are on call. Extra wheels and other parts are not carried, as the service has consisted of short hauls, generally.

The rates are as follows:

Tariff No. II is also charged for outlying calls.

Each package, valise or trunk carried outside is taxed 20 cents. Coupon books at 10 per cent. discount are sold, giving \$10 worth of rides for \$9, etc. The only flat rate in force is from the Maryland Club, which is near the garage, to the Elkridge, and which is made for club members at a distance rate, or a trifle lower.

The meters are connected with the rear wheels, and but little trouble has been experienced. On a recent occasion some members of a delegation attending a convention attempted to play with the "in service" flag. They paid without protest, so the company rather enjoyed registering 30 cents every time one of the riders raised the signal.

The company maintains its own shop, making its minor repairs. Having no agreement as to tires, this part of the business is large. There is an agreement with makers of the cars to keep them running. Parts seem to be generally reliable, and no especial portion of any one machine has proven unduly troublesome. The mileage of the cabs, about 85, is considered remarkable in such a poorly paved city as Baltimore.

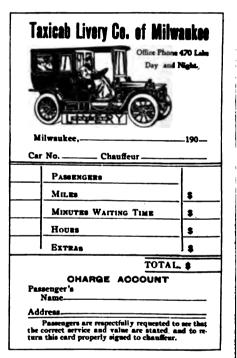

Drivers are paid 20 per cent. of collections, given their oil, and buy their gasoline at 13 cents a gallon.

The cabs are generally satisfactory, in so far as construction is concerned. It might be advisable, in some makes, to put in less costly finishing. For instance, one of the cabs came down with unusually handsome broadcloth upholstering. There were card cases, flower vases and other things. When business became brisk and this car was sent on midnight calls it soon needed refurnishing.

The service here might be improved, or rather will be improved, with heavier cabs. A telephone service to hotel and other stands, under the direct control of the company, is advisable. More advertising, too, is to be recommended. The newspaper campaign so far has been simply a statement of rates, and the riding public can be much better advised as to the inexpensiveness of the little cars. Night cab rates in Baltimore have always been excessive, and information, widely distributed, would offset the impression that the night taxi rates are higher than in the day.

# The Taxicab in Milwaukee, Wis. By W. L.

Milwaukee has never been very strong on horse drawn cabs, and has been rather slow in adopting the more modern method of transportation, the taxicab. Although there are a goodly number of private pleasure cars in use here, and quite a number of commercial cars, the renting car and taxicab have not met with much success. No private individuals operate cars with taximeters attached in the city, and there is only one company doing a taxicab business. This latter, the Taxicab Livery Company of Milwaukee, was incorporated on June 1 of the present year. The officers of the company are Dr. M. L. Henderson, president; M. Christianson, vice president, and Dr. D. I. Rowe, secretary and treasurer. The office and garage of the company is at 414 Grand avenue, in the centre of the retail portion of the city. At the present time they are operating only five cars, viz., two Maxwell, one Kisselkar, one Ford and one Rambler. The cars are equipped with various makes of tires. Franco-American taximeters are used, and

ACTUAL SIZE 31/2×51/2 HIGH.

are attached to the front wheels. No special equipment is carried for quick tire repairs, and the firm has no maintenance contracts with either tire manufacturers or car builders.

The company at present maintain one stand, on Second and Grand avenues. It is the intention, however, to place more cars in commission, and the company are negotiating with some of the leading hotels with respect to stands at their doors. The rates for one or two passengers are 50 cents for the first mile or part thereof, 10 cents for each quarter mile thereafter, and 10 cents for each six minutes waiting time. For three or four passengers the rates are 60 cents for the first mile or part thereof, 10 cents for each fifth mile thereafter, and 10 cents for each six minutes waiting. By the hour the rates are \$4 for the first hour and \$3 for each hour thereafter; \$15 for five hours and \$25 for ten hours. No extra charge is made for baggage carried inside the cab, but a charge of 20 cents is made for each piece carried on the outside.

Almost every possible method of compensating drivers is on trial. One is on straight salary, another on salary and commission and the rest are on a straight 25 per cent. commission basis. The company supplies all oils and does all repairs. The average daily mileage of each car is approximately 50. A card showing the amount collected or to be charged on each trip is made out by the chauffeur and turned in with his cash when he goes off duty. The city levies a special tax of \$5 for each car in operation, either in a taxicab or a renting service; otherwise there are no special charges for hacking.

## Taxicabs in Omaha, Neb.

While Omaha is rapidly developing into a high class metropolitan city, she has not quite reached the taxicab stage. At present there are but two taxicabs in the city. A. A. Ahlman, the owner, says, however, that so far they are not even self sustainmg. But he adds that this is due to the fact that there are not enough of them in the city to meet the demand for their services. Taxicabs, especially in these newer cities of the West, are called almost exclusively for quick transportation from one point to another to avoid the delays experienced by taking either the train or trolley cars. To make the taxicab service remunerative and popular there must be an up to date taxicab garage or stand with a sufficient numher of machines to make it possible to promptly respond to every call sent in.

While Mr. Ahlman, Chas. Thorpe, W. D. Townsend and one or two other local capstalists are organizing a company for the operation of a full line of taxicabs this winter, no immediate steps will be taken, for the simple reason that they cannot get the cabs. The big metropolitan operating companies have absolutely swallowed up the output of all the domestic as well as foreign factories.

William Drummond, one of Omaha's leading automobile dealers, says that while he has been contemplating to enter the taxicab business, he has about abandoned the idea on the ground that it is likely to prove an unprofitable investment on a small scale.

# Motor Car Post Office.

A perambulating post office having quarters on a 5 ton electric truck has been making satisfactory experimental trips in Los Angeles with a crew of four mail clerks, who, despite the handicaps imposed upon them by the lack of facilities, have been able to sort, stamp and tie out 20,000 letters daily in the time the mail usually spent on the way from the mail boxes to the post office and its sub-stations. The. trips are being continued under the direction of Superintendent of Mails H. A. Shelton, and may lead to the permanent

installation of a sub-post office on wheels in the business district.

But few changes were necessary in the truck to change it into a post office. A bench extending the full length of the truck was placed along one side, with a mail rack backing against the driver's seat and pouch holders in front of the rack. Four clerks found room on the truck. Mail was collected along a specified route from boxes, carriers, and from the chutes of office buildings. Instead of going to the main post office, the letters were at once stamped by one of the clerks, while the others sorted the letters according to destination. tied them in bundles, and placed them in pouches ready for delivery. At the end of the trip the made up mail was delivered either to the sub-station nearest to the depots or taken directly to the trains.

The average of the mail handled in the itinerant office varies between 17,000 and 20,000 pieces daily, but this average can be much increased by installing the proper facilities. Electric lights have been placed on the truck for night work, and an electric stamping machine is to be put in and connected with the batteries, performing the task of stamping the letters in one-third of the time required by hand work. By a few changes in the body of the truck the space available for the clerks could be increased, and their working speed acceler-

## Stop Taxicab Service.

The Western Motor Car Company, of Los Angeles, has gone out of the taxicab business because the service did not pay in Los Angeles. The twenty cars operated by the company for a year have been sold to the Taxicab Company of California for use in San Francisco, and it is hardly likely that another firm will venture into the Los Angeles taxicab field for the present.

Los Angeles refused to patronize the taxicabs. When the cars first appeared on the street a year ago the prevailing rate of Eastern cities, 60 cents a mile with a charge both ways, was demanded, but the patronage was so slight that the owners were forced to reduce the rate to 40 cents per mile and charge only for the distance actually traveled by the possenger, without adding the return mileage. Even with this reduction the fares were scarce, and the service was conducted at a loss.

A number of reasons are given for the lack of taxicab users in Los Angeles. The ideal weather prevailing all the year around is one of them; the large number of touring cars and runabouts, in proportion to the population, is another reason. The excellent street car system and the absence of the hurry spirit prevalent in the business centres of the East account for another portion of the taxicab loss.

## Rural Motor Mail Collection.

W. A. Johnson, a rural mail carrier in Ottawa, Kan., some time ago disposed of his three horses and wagon, and bought

a Brush runabout for covering his routes. The cost of the car was only slightly more than that of his horse and vehicle equipment. Mr. Johnson covers a route 25 miles in length, leading through the hilly district west of Ottawa. He has eighty-four mail boxes to cover every day, and with the runabout he finds that he can make his rounds in three hours, while with horses it was a big day's work.

# Collect Peddlers' License by Motor.

The supervisors of Los Angeles County have ordered the purchase of an automobile costing \$3,000 to assist the tax collector in collecting the license fee of peddlers on the county roads. Acording to the tax collector, his deputies now reach but a small portion of the peddlers, and the loss of revenue, he stated, would pay for the motor car in three months. The tax collector's automobile will make the seventh motor car owned by the county.

## Commercial Notes.

Ronk & Searles, plumbers, at Delavan, Wis., have purchased a Randolph delivery truck for their business. Mr. Ronk drove the truck from Chicago to Delavan.

The Palace Livery and Boarding Stable, Peoria, Ill., have decided to enter the taxicab field, and have placed an order for cabs with the Sultan Motor Company, of New York.

Elmer E. Day, of Port Angeles, Wash., has recently purchased a five passenger touring car, which he intends to use in connection with his livery and stage line to Lake Crescent.

The McAllister - Newgood Company, Minneapolis, Minn., have placed in service the first taxicab in the city, a Ford. They will shortly have eight or ten cabs in service from a stand at the new Radisson Hotel.

An automobile freight service has been inaugurated between Lagona and Santa Ana, Cal. A 35 horse power car is used, which covers the distance of 20 miles in less than two hours. This machine will supplement the passenger service of two machines, which have been in operation for some time.

George W. Lindermuth, of Dayton, Ohio, has put in service a twenty passenger motor sightseeing car between Dayton and Belmont. Mr. Lindermuth will shortly receive a second similar car, and will operate the two on a regular schedule, charging the same fare as is charged on the inter-urban electric line.

A 1910 model Peerless touring car has been received by the city of Milwaukee through the agency of August Jonas Automobile Company for the use of the common council committees and the board of public works jointly. The city clerk is empowered to issue certificates for the use of the machine. Frank Toenhardt, for two years chief elevator operator in the city hall, has been named official driver of the car.

## A Renard Train Service in France.

BY FRANK C. PERKINS.

The accompanying illustrations show the Renard train of passenger and freight cars hauled by motor tractor, running between Boulogne, Wimereau, Ambleteuse and Andresselle, France. The motor tractor is equipped with a 75 horse power four cylinder engine, which supplies power to the cars by means of a shaft which extends through the whole train, each carriage or omnibus being practically independently driven, although from a common source of supply. The cars have three pairs of wheels, the end wheels being used for steering and the centre pair of wheels as drivers, the power being taken by means of a gear box from the shaft which runs through the train and provided with universal

In order that this "multiple-unit system" may be made practical it was necessary to provide means to keep a definite portion of the load upon the driving wheel, and a special system of spring compensation was therefore adopted as one of the most important features of the Renard road transportation system: The compensated suspension provided enables any one of the six wheels to surmount an obstacle without imposing more strains upon the spring immediately above it than is indirectly applied to either of the other two springs on the same side of the frame.

The Renard road train has recently come into extensive use in Holland at Utrecht as well as at The Hague; also in Austria-Hungary at Budapest. A number of these automobile trains have also been placed in service in Servia, Germany, Persia, Spain, Portugal, Turkey, Roumania and Bulgaria.

It is stated that these Renard trains are to be used on the Indian frontier for commissariat and transport purposes as well as in Burmah and Ceylon to act as

feeders in the rice, timber and tea districts and in times of famine.

As compared with rail vehicles, the Renard train possesses many advantages, including low first cost for establishing the service, as well as flexibility and safety on hilly roads. It is maintained that there is no skidding and almost no side slip, with no undue wear and tear of roads. There is no fixed limit to the weight or length of the train, with absolute single handed control from the locomotive, greatly reducing the cost of operation. There is said to be no difficulty in backing out of awkward positions, and it is said that the train is able to travel over roads that are unsuitable for exceptionally heavy traffic, such as traction engines, on account of weakness of bridges or inadequacy of the road foundations. There is a great advantage in the lightness possessed by this train, and the steering arrangement, comprising a series of tillers connecting the front of each car with the back of the preceding one, is such as to cause every vehicle to follow accurately in the track of the locomotive, and giving the impression that the train is being run on rails.

# Carbonic Acid Gas Tire Inflaters.

Another tire inflation apparatus working with carbonic acid gas has been brought out in Switzerland, and is marketed under the trade name "Sodax." It consists of a brass tank about 7 inches in diameter by 14 inches high, in which is contained a wire basket that can be moved up and down from the outside. This basket is filled with ordinary soda (hydrogen sodium bicarbonate). About half a quart of water, slightly acidulated with a small bottleful of sulphuric acid, is poured into the tank and stands about 134 inches high in it. When the inflater is to be used it is first connected by a tube with the tire valve, and the wire basket is then lowered into the liquid. Gas generation begins at once, and when the pressure gauge shows the desired pressure of inflation the tube is disconnected. The gas produced, which is evidently carbonic acid gas, is said to be neutral, heavier and denser than air, and to have a preservative effect on the inner tubes. It has been shown, however, that the walls of the inner tubes allow carbonic acid gas to penetrate through them faster than air.

Vanderbilt Cup Race Set for

October 30.
The Motor Cups Holding Company held a meeting at the office of Wm. K. Vanderbilt, Jr., in New York, on Monday of this week, and unanimously decided to hold the Vanderbilt Cup Race again this year, setting the date for October 30. It will be held over a shorter circuit than last year, less than 15 miles in length, partly over the Long Island Motor Parkway, and partly over State roads, but the grand stand, and the start and finish will probably be at the same point as last year. Practically all the details of the race were settled at the meeting. Since the formation of the Motor Cups Holding Company, several weeks ago, the manufacturers who patronize races have been sounded as to their willingness to enter the event, and the result was so encouraging that it was decided to go ahead with the preliminaries. The details will probably be announced during the latter part of this week.

# New Garage for Manchester, N. H.

The Cooke, Fitz & Dillingham Company (Inc.), composed of Messrs. F. V. Cooke, E. C. Fitz and N. S. Dillingham, of Manchester, N. H., agents for Cadillac cars, will take possession of their new fireproof garage about November 1. This garage is located on Lowell street very near Elm street, the principal business thoroughfare of the city, and will be 150x45 feet in size, two stories high in the rear, and one story and basement in front. Brick walls, steel beams and cement floors will be used. and a strip of land 30 feet in width on one side of the building will be utilized for a rear approach, an outside washstand and a gasoline supply for cars which are not driven into the building. This garage will do a regular and transient business, and will be equipped in the most approved style. Messrs, C. C. and J. C. Hayes are putting up the building to lease to the Cooke Com-

A large salesroom is maintained by this concern at 1222-1224 Elm street, and also another fireproof garage at 16 and 18 Myrtle street, which is reserved particularly for the accommodation of their Cadillac customers.

Arthur Patterson has been appointed receiver for the Ovington Motor Company. importers of motorcycles, 2234 Broadway, New York, and has been authorized to continue business twenty days. The assets consist of motorcycles and supplies, \$1,000. and accounts, \$2,500.

FRENCH AUTO TRAIN AT AMBLETEUSE LA CHAPELLE SAINT PIERRE.

# Speedway Law Introduced in British Parliament.

A rather important bill was introduced in the British House of Commons by Secretary of the Treasury Lloyd George about a fortnight ago. It provides for the creation of a new body, to be known as the Road Board, which is to have powers to improve existing roads with respect to their fitness for motor traffic, and to construct new roads for motor traffic exclusively. This new bill is apparently part of the Lloyd George program, which includes the taxation of gasoline used in automobiles and the compensation of motorists for this tax by the diversion of the revenue derived from it for road improvement purposes.

The bill provides that all projects for the construction of special roads must be approved by the Treasury Department. The Road Board may consist of any number of members the Treasury may deem suitable, but only one, either the president or vice president, is to be a salaried member. The powers of the Road Board include the construction and maintenance of new roads, and the making of advances or grants to highway authorities for the construction of new roads or the improvement of existing roads, for facilitating motor traffic. The powers of the board will be similar to those of the County Councils, except that it cannot impose any taxes. The board may regulate the traffic on the roads it constructs. It has the power to admit other than motor traffic to these roads, and to exact tolls from such other traffic. The board also has power to acquire land on both sides of any proposed new highway to a distance of 220 yards from the middle of the proposed highway. so that it may profit by the appreciation of values in the vicinity of these highways. The Road Board may also sell, lease and manage the lands acquired in accordance with this act, subject to the approval of the Treasury Department. The expenses of the board, in so far as sanctioned by the Treasury, are to be defrayed out of the Road Improvement Grant, and all sums received by the Road Board are to be turned over to the Road Improvement Grant. The Road Board is to make an annual report to the Treasury. The regular automobile law is to apply to the special roads constructed by the Road Board, the same as it does to public roads, with the exception of that section which limits the permissible speed.

# Did Not Want His Car's Speed to Be Ascertained.

A rather peculiar incident arose during the trial of a speed case in England recently. Defendant was accused of driving at a rate of speed exceeding 33 miles per hour, while he himself claimed that his speed had not been more than 10 to 12 miles per hour, and submitted expert testimony to the effect that the car was not capable of doing better than 25 miles per hour. The jury was undecided, but gave the defendant the choice of two alternatives: They would either dismiss the case on payment of costs or the defendant could turn over his car to an impartial expert to determine what its speed limitations were. Defendant preferred to pay the costs.

# Cab Chauffeurs to Prison for Robbing Woman Fare,

Two New York cab chauffeurs, William B. Curzon and William H. Young, were sentenced on Tuesday to serve not less than two and a half years and not more than five years in the Sing Sing Prison. They were arrested over a month ago charged with having attacked and robbed a woman whom they picked up in their automobile as a fare. They took \$25 from her.

## Legal Notes.

About 500 driver's registration badges have been received by the Indianapolis city controller, and have been issued to the first 500 persons applying for registration. About 1,000 have applied for registration to date, but owing to a delay in getting the badges the ordinance requiring registration is not being enforced at the present time

At the coming session of the Indiana Legislature a bill will be introduced making it the duty of county commissioners to post guide and danger signs on all public highways. There is much agitation among automobile interests for such a law, as the Indiana highways have no signs at the present time. Efforts will be made to assess a penalty if county commissioners fail to comply with the law.

# Petition to Have National Park Roads Opened to Autos.

A petition has been sent to the Secretary of the Interior at Washington, D. C., by the California Promotion Committee, requesting that certain roads in the Yosemite National Park be opened for the limited use of automobiles, so as to enable many people who would otherwise not be able to visit the park to view its scenic wonders. The committee had the petition prepared last May, and it has since been signed by many commercial organizations and others, having been circulated all over the State.

# Firestone Tire Company to Build New Plant.

At the recent regular annual meeting of the Firestone Tire and Rubber Company, Akron, Ohio, the following officers were elected: H. S. Firestone, president and general manager; Will Christie, vice president; S. G. Carkhuff, secretary, and L. E. Sisler, treasurer. The annual report is said to 13d of mode 30 sales up as easily us mous cent. over the previous fiscal year. The company have purchased a 15 acre tract of land near their present plant, on which they will erect a large new tire factory.

# Meteor Motor Car Company's Factory Burned Out.

The Meteor Motor Car Company, Bettendorf, Ia., had a disastrous fire on September 9, which completely destroyed the entire factory, with the exception of the office building. We are informed that all drawings, patterns, jigs, special tools, etc., in fact all necessary material for starting work on 1910 models, were saved, and the company will do everything in their power to get work started again. How long it will be before they will be in actual operation again it is impossible to say at this time.

# Smiths Resign from Olds Motor Works.

Frederick L. Smith and Angus Smith, vice president and general manager and secretary and treasurer, respectively, of the Olds Motor Works, Lansing, Mich., have resigned from the company, and Bentley J. Mead, general sales manager of the General Motors Company, has been appointed secretary and general manager of the firm. The Olds Motor Works was one of the two firms which originally composed the General Motors Company. The Smiths have been connected with the Olds Motor Works since its establishment in Detroit about a decade ago. Ralph R. Owen, factory manager of the Olds Works, has also resigned, and it is reported that the Smiths and Owen will organize a new company for the manufacture of automobiles in Detroit.

# Supplementary Spiral Spring Patents.

In our issue of August 25 appeared an item regarding an injunction suit brought by the Supplementary Spiral Spring Company, of St. Louis, against M. H. Cormack & Co. and M. H. Cormack, of New York, in which there are said to be several errors in the statements made to us by Cormack & Co.

The St. Louis Supplementary Spiral Spring Company patents Nos. 807,612 and 901,578, respectively, are actually issued, and relate strictly to supplementary spiral springs; while the patents of J. Hector Graham, which were quoted by Cormack, are said to relate, one to a car truck and the other to a snow plow.

Patent No. 807,612 was granted to the Supplementary Spiral Spring Company on December 19, 1905, and they claim that the interference which Graham filed against it is based on an application for a patent bearing a very close resemblance to their patent No. 807,612 as to the drawings and language.

M. H. Cormack & Co. have sold out to J. H. Graham, of Boston, to avoid liability.

Non-Slipping Metal Tired Truck

Wheels.

wheels of motor trucks non-slipping has

been discovered in France, and is described

in the bulletin of the technical committee

of the Automobile Club of France. In the

case of a large truck fitted with steel tires

8 inches wide considerable trouble was ex-

perienced in getting sufficient traction in

snow and on greasy pavements on grades.

The wheels were shod with semi-hard steel

plates, about three-quarters inch thick, with

oblique transverse edges, and a distance of

about three-quarters inch between adjacent

plates. These plates were riveted in place.

In order to prevent slipping aluminum rods

were pressed into the spaces between the

plates, so as to project very slightly above

the steel plates. In service the steel plates

slightly spread and hold the aluminum rods

very firmly. In service the projecting por-

tions are headed over, and though they pro-

jected only about one-sixteenth of an inch

it was found that the truck then had per-

fect traction, even on snow and ice. It was

experimented with for about three months.

In another case the same treatment was an-

plied to the driving wheels of a six wheeled

truck. It will be understood that the condi-

tions of traction of such a truck are particu-

A new method of rendering metal tired

# OUR FOREIGN EXCHANGES ➤

# Austrian Commercial Vehicle Contest.

The Austrian Automobile Club will conduct an international contest for commercial motor vehicles October 3 to 17. The contest will comprise a test of reliability and a determination of the fuel consumption per ton kilometre of useful load. The contest is open to all classes of utility vehicles driven by explosion motor, including doctors' vehicles, taxicabs, light and heavy trucks and road trains.

The rules, which have just been made public, require that the bodies of the vehicles must be suitable for the purpose for which the vehicles are to be used under ordinary conditions. In the case of vehicles for the transportation of passengers the seats must have a minimum width of 18 inches. In the case of omnibuses if two classes are provided for the respective spaces must be separated by a partition. The windows in the front wall must be closed during the runs. In case any panes in these windows should break during the test they must must be replaced by boards or heavy cardboard.

Every vehicle must be provided with a fuel tank of sufficient capacity to complete the daily stage without replenishment of the fuel supply. The competing vehicles will be divided into three groups, and will be tested on three closed routes of a total length of approximately 750, 1,000 and 1,625 miles, respectively. The circuits will be so laid out that the vehicles of all classes will stop over night at the same points. The division into groups and classes is as follows:

### GROUP I.

(125 to 145 m, p. h. per day.)
1. Doctors' cars and motor taxicabs.

### GROUP II.

(75 to 94 m. p. h. per day.)

- Closed omnibuses with seats for eight to fourteen passengers.
- Closed omnibuses with seats for more than fourteen passengers.
- 4. Delivery wagons for 1,100-2,200 pounds useful load.
- 5. Trucks for 3,300-4,400 pounds useful load.

# GROUP III.

(50-62 m. p. h. daily.)

- 6. Trucks for 5,500-7,700 pounds useful load.
  7. Trucks for more than 8,800 pounds useful load.
- 8. Motor road trains with one or more trailers.

All vehicles must be submitted to the committee in running order on October 1. The vehicles will be loaded exclusively with ballast, consisting of substantial boxes of 220 pounds weight each, fitted either with gravel, broken stone or metal bars. The load in the case of omnibuses is to consist of ballast in durable sacks of 66 or 154 pounds, respectively. A sack of 154 pounds is to represent a passenger, and a sack of 66 pounds the baggage. Loss of ballast, as well as damaged seals, will lead to disqualification.

All competing vehicles are to be accompanied by official observers, whose assignment will be determined each day by lot. Each observer will be furnished an observer's entry book, which it will be his duty to fill out during the run, and to deliver to the committee in charge each evening inside of an hour after his arrival. The observers are also required to see to it that their vehicle carries the prescribed load; that it complies with all legal requirements; that all necessary repairs are made with equipment carried along on the car, and that in the fuel consumption trials none but officially measured fuel is used.

The competing cars will be started each morning at 7 o'clock, in the order of their estimated speed, at intervals of two minutes. At night the vehicles will be stationed in a closed park to which only the committee in charge, the observers and certain other specified persons will have access. The driver and mechanic of competing vehicles will be admitted to the park one half hour before their starting time in the morning.

The following minimum speeds must be maintained by the competing vehicles:

Doctors' cars and taxicabs, 151/2 miles per hour.

Delivery wagons and trucks:

Useful load up to (pounds)...... 2,200 3,300 4,400 5,500 6.600 7,700 8,800 11,000 and over. With steel tires (m. p. h.)...... .... 6½ 6 5.6 5.3 5 4.4 With rubber tires (m. p. h.)..... 11½ 10 9.4 8.4 7.5 7.2 6.9 6½ Motor road trains, 4.4 m. p. h. on steel tires, and 5.6 m. p. h. on rubber tires.

Every contestant is required to inform the committee in charge in advance of the kind and quantity of fuel required by his car, which will then be supplied by the committee at the different stopping points at the expense of the contestant. The same fuel as used during the fuel consumption contest must be used throughout the trial, and it is not permitted to use another fuel for starting purposes. Anti-skidding devices may be secured to the driving wheels, but the time used in applying and removing them will be counted as running time.

The fuel consumption contest will be held October 12, 13 and 14. The contestants are required to provide all of the connections of the fuel system, such as filling caps, drain cock, carburetor connection, with means which permit of the ready application of seals. For the different fuels admissible, viz., gasoline, heavy gasoline, benzol and kerosene, the current prices on October 1 will be charged in making up the conomy records.

Numerous prizes, both cash and plate, are being offered in connection with the contest. Exhibitions of the competing vehicles are to be held in Prague, Reichenberg and Vienna. The entry fees vary from 150 crowns for cars in Class 1 to 400 crowns for cars in Class 8, up to the preliminary closing of entries on September 15, and between twice these amounts from that date up to September 25. Entries are received by the general secretary of the Austrian Automobile Club, Vienna I, Karntnerring 10.

larly unfavorable, for the reason that a smaller portion of the load is carried on the driving wheels. Under these conditions it was practically impossible to ascend a grade, especially when the truck was empty. The wheels were fitted with aluminum rods, as described above. In the course of a few days the aluminum had worn even with the outer surface of the steel plates, and since that time the truck has been driven without the least trouble from slipping. It seems that the result obtained is due to the malleability of aluminum, which permits the peb-

# Duty Free Reimportation of Automobiles into Germany.

bles to imbed themselves in it.

The German Minister of Finance has given his permission to the duty free reimportation of automobiles which have temporarily been taken out of the country, on the basis of the now customary export certificates, without the application of seals to the automobiles, under the following conditions: The certificates must bear the name and place of residence of the owners, as well as a precise description of all the more important characteristic features of the car, including the approximate weight of the car, its number, color of chassis (i. e., the wheels and the frame), the number of the chassis, the type and the color of the vehicle body, the number of seats, the character and color of the upholstering, as well as any special characteristics, such as insignia, initials, etc. Cars may be reimported at any office.

# Experimental Road Work in Ohio.

State Highway Commissioner J. C. Wondders, of Ohio, will this week commence the work of putting down the State's share of the one mile of experimental road which is being constructed just east of Columbus, with a fund of \$10,000 furnished by the last Legislature. The results of this test of road making materials will be watched with interest by road makers in all parts of the country, as, aside from a somewhat similar experiment being made by the Federal Government, it is the only one of its kind in the world. The Ohio test road differs from the Government road in the length of the strips of various kinds of road, and in that the State has gone into the market and paid cash for all the materials it has used, while the Government is making its tests with donated material, it is said.

Eleven manufacturers of twelve different kinds of road surfacing or dressing agreed to send experts to superintend the work of putting the material on a stretch of road, and nine of them have done so. The tenth will start work this week, and the highway department is endeavoring to get the eleventh to send on a man as soon as possible, as the material is at hand, ready for use. Three sections will be built after plans of the State Highway Department by the department itself, to test its methods in comparison with the patented or manufactured materials or processés.

The department started on the work with the idea of getting the material such as is offered regularly on the market, and not an extra good quality, selected and prepared with care—if this was possible. It then proposed to have this material applied under the direction of an expert connected with the company manufacturing it, so that the conditions of putting it down would be the best possible, and there could be no complaint that the road might have worn better had it not been built by inexperienced men. Any of the manufacturers would have donated the material for the test, but the State preferred to buy, and would accept no donations.

Sections of road have been built with material manufactured by the following firms, the material and its description being also given:

Pioneer Asphalt Cement—An asphaltic product mined in Utah by the American Asphaltum and Rubber Company, of Chicago. This cement is applied to the top course.

Tarvia X—A coal tar preparation manufactured by the Barrett Manufacturing Company, of New York. It is applied by compressed air while at a temperature of from 250° to 300° Fahr. to the top course as a filler.

Tarvia B—A coal tar preparation manufactured by the same company. It is applied cold as a surface treatment, and is described as of "less tenacity and lower viscosity than Tarvia X."

Liquid Asphalt—Another asphaltic preparation, a filler, which is manufactured by the Indian Refining Company, of Cincinnati. It is a manufactured product "carrying in solution 60 to 65 per cent. of asphalt fluxed with other constituents of a non-volatile nature."

Fairfield Refined Asphalt Cement—A product consisting of 88 per cent. bitumen, and 12 per cent, mineral product, used as a filler. It is manufactured by the Impervious Product Company, of Baltimore.

Glutrin—A by-product of the manufacture of wood pulp. It is mixed with water, and applied by the use of a sprinkling wagon to an ordinary water bound macadam road, becoming hardened as it dries, which is very shortly after application. Manufactured by the Robeson Process Company, of Au Sable Forks, N. Y.

Carbo-Via is a coal tar product, used as a filler, manufactured by the Continental Bitumen Company, Toledo.

Road Coating—A tar preparation. It is used as a bituminous binder. Manufactured by the United Gas Improvement Company, of Philadelphia.

Asphaltoilene is described as "a product equivalent to pure asphalt dissolved in petrolene." It is a filler manufactured by the Good Road Improvement Company, of Cincinnati.

Wadsworth Macadam is a top dressing made from ground Kentucky asphalt, containing not less than 8 per cent. bitumen. It is manufactured by the Wadsworth Stone and Paving Company, of Pittsburg.

The "Petrolithic" road will be built this week. Mr. Frees, the treasurer of the company, has gone to Indianapolis to get some additional needed machinery, and the company's chief engineer, Mr. Postle, of San Francisco, will be in Columbus this week to superintend the work. This is a process of treating a road with California asphaltic oil by means of the Petrolithic rolling tamper. This work is done by the Petrolithic Pavement Company, of Los Angeles, Cal.

The three sections of the road to be built by the State Highway Commission, under specifications laid down for counties working under direction of the department in expending State funds appropriated by the Legislature for good roads, will be concrete macadam, gravel concrete and the ordinary water bound macadam. The concrete macadam is a process in which a grout of cement is rolled into the voids of an unfilled macadam road. The gravel concrete road is a concrete roadway built of gravel and cement. The State Highway Commissioner has built concrete macadam streets in Bellefontaine, which have been in use for some time, and have shown good wearing quality, the objection to them being that they are too slippery.

One section of the new experimental road has already failed—as each section is thrown open to travel as soon as it is constructed. This section is that prepared by the Standard Oil Company. The company

has two preparations, and there seems to be a misunderstanding as to which it was intended to use on this particular stretch. One of them is Standard Macadam Asphalt Binder, "a heavy product, almost solid asphaltum," poured upon the top layer of the stone. The other is Standard Asphalt Road Oil, "a manufactured product containing from 30 to 50 per cent. of petroleum asphalt"—a surface treatment. Whichever the company used or intended to use, its superintendent admits it is not satisfactory, and asks permission to build another section, to make another test.

Taroid is a coal tar pitch prepared in liquidized form, and used as a binder. The State has the material on hand, but the company has sent no one to superintendent its use. It is prepared by the F. J. Lewis Manufacturing Company, Chicago. If a representative of the company does not come to superintend, the material will not be used, in all probability.

The experimental road is located about one mile east of Columbus, and is known as Nelson avenue. It extends from St. Mary's Academy at Shepard, a suburb, and extends southwardly to the corporation line of Columbus. It connects at its northern terminus with Fifth avenue, the principal thoroughfare east and west on the north side of Columbus, and at its southern end with Broad street, the principal residence street of the city. It is thus a much traveled road, as it is a part of a circuitous route through the prettiest residence section, out through the country to Shepard, and back to Columbus' principal business street, High street. It is used a great deal by automobiles, and this was one of the reasons why it was selected.

The various sections are laid as a continuous road, so that one section will receive just as much wear as another. The sections are 400 feet long, and the roadway is 16 feet in width. Of the \$10,000 allowed by the Legislature, the Highway Commissioner has remaining \$4,407.98. A visit to this road will be one of the events on the program of the coming convention of the American Road Makers' Association.

## Trade Literature Received.

Thermoid Rubber Co., Trenton, N. J.—Dealers' price list of tires and inner tubes.

Winton Motor Carriage Co., Cleveland, Ohio.—Catalogue of the 1910 Winton Six.

Mercer Automobile Co., Trenton, N. J.—Circular describing the Mercer automobile.

The Sharp Arrow Automobile Co., Trenton, N. J.—"The Sharp Arrow Automobile."
Firestone Tire and Rubber Co., Akron, Ohio.—

Booklet on Firestone demountable rims.

The Edgemont Machine Co., Dayton, Ohio.—
Catalogue C of the Edgemont friction clutch.

Ewing Automobile Co., 1303 Citizens Building, Cleveland, Ohio.—Advance sheets of Ewing 1910 catalogue.

Universal Rim Co., 1467 and 1469 Michigan avenue, Chicago, Ill.—Circular of the Universal demountable rim.

Peerless Motor Car Co., Quincy avenue and E. Ninety-third street, Cleveland, Ohio.—Booklet on the equipment furnished for Peerless Models 27 and 28.

# MINOR MENTION

The Powel! Supply Company, Omaha, Neb., have secured the agency for the Goodyear air bottle for inflating tires.

The Acme Rubber Company, Trenton, N. J., are erecting two new wings, one 250x 60 feet and the other 100x40 feet, which they expect to occupy about October 1.

The Western Rubber and Supply Company, Los Angeles, Cal., have moved to 1011-15 South Olive street, a district where many garages have recently been located.

The capital stock of the John W. Brown Manufacturing Company, Columbus, Ohio, has been increased to permit of enlarging the automobile lamp department. Additional machinery is to be installed.

The E. Z. Auto Go-Cart Company, of Monroe, Wis., has purchased the plant of the Blue Label Cheese Company at Monroe, and will remodel it. The company recently moved its plant to Monroe from Beloit, Wis.

Nordyke & Marmon, of Indianapolis, Ind., have come forth with a statement to the effect that they will never again participate in track races. They have never built any racing cars, and do not intend to do so in the future.

Rauch & Lang, of Cleveland, Ohio, plan to built 1,000 electric vehicles the coming season. These cars are to be equipped with a special cushion tire made by the Motz Tire Company, of Akron. This tire has a double tread with corrugated surface.

It is reported from Saginaw, Mich., that the General Motors Company have secured an option on the plant of the Jackson-Church-Wilcox Company, which for some time has been manufacturing parts for the General and other automobile companies.

The new plant of the Waukesha Motor Company, of Waukesha, Wis., is nearing completion, and will be ready for occupancy about November 1. The main building is one story high, 85x120 feet, with a two story wing, 30x40 feet, all of solid brick construction.

The Moline Automobile Company, East Moline, Ill., has let the contract for the erection of an additional building, 100x125 feet, and four stories high. This will give the company 50,000 square feet of additional floor space, which will be used for chassis and body assembling, and as a warehouse.

The West Milwaukee shops of the Chicago, Milwaukee & St. Paul Railway Company have just turned out fifty freight cars designated "automobile" type, which will be placed in the motor car transportation service at once. The company, since opening its Pacific Coast extension, has had a heavy motor car traffic. The cars are 41 feet long, with especially large side and end doors,

permitting of loading and unloading motor cars without twisting, cramping or scratching.

The Lexington Automobile Company, of Lexington, Ky., is considering removal to Connersville, Ind.

Jas. F. Hill, of Fleetwood, Pa., has invented a new gasoline engine which is claimed to give an exceptionally large output in proportion to its size. It works on the scavenging principle.

The recently incorporated Badger Auto Company, of Oshkosh, Wis., plans to build a line of motor trucks. The company has leased the Termaat & Monahan Company's plant at Oshkosh. The owners of the latter company are included in the list of incorporators of the new concern.

Work has been begun at the factory of the Lion Fence Company, Adrian, Mich., to fit it up as an automobile factory for the manufacture of the Gyroscope car. It is stated that \$15.000 of the stock of the Lion Motor Company, as the new concern is to be known, has been subscribed for.

E. G. Atkins, Minneapolis, Minn., has designed a new floatless carburetor in which the gasoline adjustment is automatically varied with the throttle adjustment. He is now organizing the Atkins Manufacturing Company for manufacturing the device, and will locate in Minneapolis or Duluth.

The Lexington Motor Car Company, Lexington, Ky., which was incorporated about a year ago, with a capital stock of \$50,000, at a meeting on September 2 decided to increase its capitalization to \$100,000. The officers of the company are: F. T. Bryan, treasurer, and Fred N. Coats, Kinzea Stone, J. C. Moore, B. F. Stone, V. K. Dodge and V. A. Bradley, directors.

The Napier Company of England has brought out a signal horn operated by the usual rubber bulb, which is claimed to be unaffected by dirt and water. The horn is substantially of spiral shape, with the mouth at the centre. It is claimed that any water which by chance enters the mouth runs out again and cannot possibly reach the reed. The wind rush is broken, and the consequent muffling of the horn obviated.

Jas. Cunningham, Son & Co., of Rochester, N. Y., manufacturers of heavy horse vehicles and hearses, have been reorganized with a capital stock of \$1,200,000, and will take up, in addition to their horse vehicle business, the manufacture of automobiles. Experimental work with automobiles was begun some months ago, and now the regular manufacture of these machines is to be taken up in the same factory as that of the horse vehicles.

The Cataract Motor Company, of Paterson, N. J., whose incorporation we announced in our last week's issue, plan to manufacture motors and change gears for automobiles, according to manufacturers' specifications. Several of the incorporators were formerly connected with the Rogers Locomotive Company, of Paterson. It is the intention to locate in Paterson if the

citizens of that city will subscribe for \$200,000 of the \$350,000 stock of the company.

The Continental Caoutchouc Company has opened a Boston branch at 895 Boylston street, in charge of E. H. Kidder.

An automobile sales building is being erected on a plot on Euclid avenue, Cleveland, Ohio, just east of East Twenty-second street, which will cost approximately \$40.000. The property is 99x198 feet, and has been leased for a long term of years, with an option to buy in ten or twenty years.

The R. L. Kenyon Company, of La Crosse, Wis., manufacturer of tops, cushions, seats and outfitting for motor cars and boats, has practically decided to move to Waukesha, Wis. The capital stock will be increased from \$25,000 to \$50,000. The Waukesha Business Men's Club is promoting the removal.

The Remy Electric Company, Anderson, Ind., will establish branch selling offices in Kansas City and San Francisco on January I, 1910. The San Francisco branch will be in charge of Edward F. Willett, now connected with the company's New York selling office, while the Kansas City office will be managed by Ross E. Luellen.

The York Automobile Company, of York Pa., is reported to be considering removal to Trenton, N. J. President O'Connor, of the York Company, has recently made a number of trips to Trenton, and F. J. Wetzel, of the Wetzel Mechanical Stoker Company, of Trenton, has been active in the interest of the company in Trenton.

New York State will be represented at the National Good Roads Convention at Cleveland, September 21-23, by six delegates, viz., S. Percy Hooker, Robert Earl and Thomas Warren Allen, of the State Highway Commission, and Frank N. Godfrey, of Olean; W. Pierrepont White, of Utica, and Albert L. Shattuck, of New York.

The Sterling Machine and Stamping Company announce the removal of their plant from Vermilion to Wellington. Ohio, and will open their new factory at Wellington with a full force about September 20. The company manufacture gas generators, tire lugs and other stamped parts of brass and steel. They will add a brass foundry to their plant.

For the Frank A. Munsey reliability run from Washington to Boston and back, September 21-29, thirty-seven entries were received up to the time of closing on September 11. The competing cars will be run in six divisions, and prizes will be awarded in each division, in addition to a general sweepstake prize for the car making the best score. The entrance money will be divided among the drivers of the six winning cars.

It is the intention of the Swiss Government to require all vehicles to be equipped with tachometers, which are to be of such design that the speed can be plainly read off by all persons in the vicinity.

Garage Notes.

C. H. Nass is erecting a garage in Esmond, N. Dak.

A. R. Mires has purchased the Young Garage in Modesto, Cal., and will install a repair shop.

I. D. Hawley, St. Cloud, Minn., plans to add an addition to his garage to double its capacity.

N. J. G. Morrison and W. W. Shelp have bought the garage of O. V. Armstrong, Litchfield, Minn.

The Berks Auto and Garage Co., Reading, Pa., are adding a machine shop, 100x60 feet, to their sarage.

Gus Jenevein, San Mateo, Cal., is erecting an automobile repair shop near the Junction House in that city.

John Moberg has let the contract for the erection of a garage building in Bemidji, Minn., to cost about \$4,000.

Fred Smith will open a garage in Xenia, Ohio, in the Whiteman Building, corner of Whiteman and Second streets.

The Barkman Electric Co. of Salt Lake City, Utah, has changed its name to the Standard Electric and Automobile Co.

Otto Scherer, Palmyra, Wis., plans to erect a garage building, 52x72 feet. It will include a repair room and a paint shop.

E. L. Leinbach, who represents the Oldsmobile in Baltimore, Md., has decided to erect a modern garage and salesroom building.

Rex Lindemann, Endilin, N. Dak., has engaged in the automobile business and taken the agency for the E-M-F and the Overland cars.

Will Cooper, Fort Jones, Cal., has sold his interest in the Yreka Garage to his partners, and will be succeeded by Rolland Baker as manager.

The Vale & Menhall Co., Beloit, Wis., has been organized to conduct a garage. The new company will be agents for the Marion and Overland automobiles.

The Mich-Stair Automobile Co., Minneapolis, Minn., has purchased a building site on Eighth street and First avenues North, and will erect a garage in the near future.

E. C. Lou has bought the Bailey Street Garage in Whittier, Cal., from C. W. Harvey. Mr. Lou was formerly connected with several automobile factories in Cleveland. Ohio.

Thompson & Slattery, Spirit Lake, Ia., have bought the H. A. Wilsey garage, and took possession on September 1. An addition is now being erected at the south side of the building.

The Horton Wagon Manufacturing Co., Augusta. Ga., at a recent directors' meeting decided to erect a garage building on Ellis street. It will be fully equipped with all modern garage conveniences.

Frank P. Cook, Torrington, Conn., is erecting a two story brick building, 49x58 feet, with a tar and gravel roof, of which the first floor is to be used for a garage and the second floor for tenement purposes,

The Dietrich Motor Car Co., of Allentown, Pa., are erecting a three story concrete garage building. 285x80 feet, on Linder street, between Ninth and Tenth. The garage will contain 70,000 square feet of floor space.

The Lawfer Automobile Co., Allentown, Pa., have given up the agency for Ford cars, and taken on the Hudson and Chalmers-Detroit. They have a garage at Twelfth and Hamilton streets, and an office at 27 North Eighth street.

The building at the north side of Twenty-fifth street, near Eleventh avenue, New York, which was formerly occupied by the Cornell foundry, is to be reconstructed to serve as a garage for the delivery wagons of the Wanamaker store.

The Reading Automobile Co., Reading, Pa., have commenced work on a new garage at Fifth, near Washington, directly across from the Orpheum Theatre. The building will be a three story structure of reinforced concrete, costing \$60,000. They expect to occupy it about January 15.

The Knox, which has heretofore been handled by John A. Boyd as agent at Indianapolis, will be looked after by the newly organized Conduitt Automobile Co. in that city. A building at 332 and 334 North Delaware street has been leased, and a salesroom and garage has been established. Mr.

Boyd will continue in an active capacity with the new company.

A galvanized iron garage is to be erected in Kern City, Cal., on I street, next to the Wells-Fargo Building.

Elmer Allen, Independence, Mo., has leased the skating rink building at South Main and Kansas street, and will fit it up as a garage.

Work has been started on a new garage for E. C. Barber, on Summit avenue, Summit, N. J. The building is to be finished before November 1.

Roby Moore, Ocean Park, Cal., has bought the "Auto Inn" Garage on Pier avenue, and will remodel and enlarge it. Mr. Moore has the agency for the Overland line.

The new garage of the Bayside Automobile Company, Flushing, N. Y., has been completed and opened for business. It is located on Broadway near Belle avenue.

The firm of Macer & Peterson, who conducted the Commercial Street Garage in Kewanee, Ill., has been dissolved, and the business will be continued by Wilbur H. Peterson.

Albert R. Shattuck and Geo. F. Chamberlin have let the contract for a twelve story light manufacturing and automobile building at 244-252 West Fifty-fourth street, New York city.

T. L. Patterson, Albany, Ga., has bought a building site at the corner of Plint street and the Court House alley, and intends to erect a garage building. The lot is 67x210 feet, and is centrally located.

The Maxwell-Briscoe Motor Co. has organized a branch sales company in Louisville, Ky., of which R. H. Edelan is president, Dr. F. S. Clark vice president and treasurer, and T. L. Marshall secretary and general manager.

The Myers Garage has recently been opened in Bushnell, Ill., on West Main street. The garage comprises a completely equipped repair shop, as well as a compressed air plant and other modern garage equipments. Frank Dill has charge of the mechanical department.

T. E. Smith, Salt Lake City, Utah, has bought the garage located in Post Office place, and is erecting a new fireproof building in State street, which will be ready for occupancy in about sixty days. The new building will be 76½x247 feet. It will comprise a repair shop and a supply salesroom.

The Imperial Motor Co. has been organized at Kansas City, Mo., by W. F. Turrell, president; Gail Reed, vice president and sales manager, and O. E. Dodge, Jr., secretary and treasurer. The company has purchased the Cowie electric garage at 3313-15 Troost avenue, and will handle the Woods electric.

The firm of Lovell & Hege, Clinton, Ia., has taken a five year lease on a new one and one-half story, 100x47 foot garage building that is being erected on Second street, between Third and Fourth avenues. The company has the agencies for the Regal and Haynes cars, and intends to also take on a low priced runabout.

The Lee Motor Car Co., of Los Angeles, Cal., has decided to establish a branch agency for the Cadillac car in Pasadena, under the management of L. G. Pattee. The company has bought a building site at the corner of Union street and Broadway, and will immediately erect a 100x140 feet brick and concrete garage, to cost about \$25,000, which will be completed about October 15.

The Central New York Automobile Co. has been organized at Oneonta, N. Y., with a capital stock of \$50,000, and has bought out the business of I. Van Ettem, who conducted the Oneonta Automobile Station on Dietz street. The new company has the agency for Buick cars. A new fire-proof garage building, three stories high, will be erected at a cost of \$25,000. Frank G. Anderson will act as general manager of the company.

The Henderson Automobile Co. has recently been organized in Vinton, Ia., with the following officers: D. L. Bryan, president; C. A. Kling, vice president; John Lorenz, treasurer; J. P. Whitney, secretary, and Chas. Henderson, manager. They have secured a two story building and reconstructed it as a garage. It has a capacity for fifty cars, and is fully equipped with an air compressor, wash rack and machine shop equipment. The

company intend to secure the agency for several lines of high class cars.

The Oakland Motor Car Co, have recently opened their Seattle, Wash., salesroom at 312 East Pike street.

Richard Patterson has retired from the agency and garage concern of Holloway & Patterson, Monroe, Wis., and Percy Holloway will continue the business.

The Krueger Auto Co., of Oshkosh, Wis., has reorganized under the name of the Oshkosh Motor Car Company. J. A. Crum is president and Frank Blum is secretary.

F. W. Vogler and Norman Devoe have recently taken the agency for Buick cars in Portland, Ore., and will cover the territory in Oregon, Washington and northern Idaho.

Chalenor & Saylor, formerly implement dealers, of Palouse, Wash., will hereafter give their attention to automobiles, and have recently received two carloads of machines.

Emanuel L. Phillipp, president of the Union Refrigerator Transit Co., of Milwaukee, Wis., is building a \$10,000 private garage near his residence on Hackett avenue, Milwaukee.

The Stoddard-Dayton agency in Seattle, Wash., will be located in the old Capitol Hill Garage at Nineteenth avenue and East Roy street. Ira D. Lundy is the manager for the Seattle house.

The Metropolitan Motor Car Co., Seattle, Wash.. is a new corporation, of which Bruce A. Griggs is manager and president. The concern will have the agency for the Acme and Pullman cars.

The Metropolitan Motor Car Co., of Seattle, Wash, plans to erect a one story concrete garage and auto salesroom in the Henry Building, adjoining the Olympic Motor Car Co. The new garage will be 70x100 feet.

Thomas A. King, a livery man of Louisville, Ky., has converted his livery stable at Second and Guthrie streets into a garage and entered the automobile business. He has the agency for the American car and the Alco truck.

The Shawano Auto Co., of Shawano, Wis., which recently rebuilt the Mehlhorn Building into a garage and salesroom, will erect a \$25,000 building next spring. It will be two stories high and have ample livery, repair and garage facilities.

James Menhall and Harry Vale, Beloit, Wis., have formed a partnership to handle the Overland and Marion cars in several counties in Wisconsin, including Madison and several other large cities. They will establish a number of subagencies.

M. S. Bringham, of the Bringham & Fenn Motor Car Co., Seattle, Wash., has bought out his partner, C. H. Fenn, and hereafter will have entire control of the company, of which he is president. Mr. Bringham has the agency for the Cadillac car for 1910.

F. A. Bennett, who has handled a number of makes of motor cars in Spokane, Seattle and Portland, intends to close up all of his Northwest stores except the one in Portland, where a part of his original line will be handled.

The Polson Implement Co. have entered the automobile field in Seattle, Wash., and have taken the agencies for the American and Maxwell lines. Marc Bunnell, who last season handled the Locomobile and Maxwell, has become interested in the Polson Implement Co., and will be manager of their automobile branch. The company will open their new garage and salesroom at 926 First avenue South on September 15.

The Hokanson Automobile Co., of Madison, Wis., the largest agency in the capital city and western Wisconsin, has reorganized under the same title, but with a capital stock of \$70,000, an increase The following officers were elected: of \$30,000. President, Charles F. Spooner; vice president. Emil Hokanson; treasurer, George P. Miller; secretary and general manager, Rudolph Hokanson. George P. Miller, of Madison, a former State Senator, will take an active interest in the affairs of the company. The garage and salesrooms on Doty street, Madison, will at once be enlarged and improved, two stories being added, and the company will begin the manufacture of tops and novelties. The company already has

several branch garages in southern and western Wisconsin, and this chain will be lengthened gradually.

Fred Ryan and Donald Jacobs, Riverside, Cal., have bought the San Jacinto Garage from W. D. Jacobs.

The Ortonville Auto and Supply Co., of Ortonville, Minn., will open a garage and salesroom for the E-M-F.

A garage is to be erected on a 100x100 foot plot at 535-541 West Forty-second street, New York city, which was recently sold.

The Keystone Automobile Co., Uniontown, Pa., is erecting a garage building on West Main street. I. W. Semans is at the head of the company.

George Kemp and Mr. Van Duell, Tarrytown, N. Y., have leased the old Hudson Valley Garage in Church street, and will conduct it as the Tarrytown Garage.

Edwin Kilburn, D. M. Peshak, W. E. Hutton and C. A. Gilbert, in Spring Valley, Minn., have organized the Spring Valley Automobile Co., to handle the Ford, Reo and Overland.

C. R. Patterson & Son, of Greenfield, Ohio, will soon begin the erection of a modern garage at that place. A representative of the concern has been sent to Columbus and Cincinnati to secure ideas for the new structure.

Work has been begun on a frame garage building for Carl Grau, Houston, Tex. The building will be located on the north side of City Hall square, fronting East Fifth street. Mr. Grau has the White agency.

Fred B. Henderson, Denver, Col., will build a garage on the site of the Metropole and Palace stables at Fifteenth and Cheyenne streets. It is reported that the Studebaker Automobile Co. has taken a long lease on the property.

J. E. Wyckliffe Goldsmith, Jr., and T. D. Meador, Jr., Atlanta, Ga., have secured a garage with salesroom and repair shop at 12 and 14 East Cain street. They have the agency for the Speedwell car and the Gramm-Logan truck.

The Love Garage Co., Columbus, Ohio, recently changed from a partnership to a corporation, will some be installed in a new structure on North High street which is being erected for the concern. The present location is West Fifth avenue.

The Colonial Motor Car Co., Springfield, Mo., will open a storeroom for new and second hand cars and for motor supplies in a building on St. Louis street. The company conducts a garage in Pickwick alley, off South Jefferson street.

The Studebaker and E-M-F agency in Columbus, Ohio, under the management of A. J. Pray, was informally opened September 6. The agency, which will not do a general garage business, is housed in a new structure 188x40 feet on North Fourth street.

Milton P. Stiles, of Ventura, Cal., is erecting a 52x100 foot two story brick garage on Main and Palm streets. The building will be in the Mission style of architecture, of pressed brick with large plate glass windows. The second floor will be used for office purposes.

D. L. Ormsby has sold the Audubon Garage and Machine Works, 415 West 150th street, New York, to E. L. Bush, who will continue it under the same name. Mr. Ormsby retains the agency for the Middleby car, and will devote all of his time to the sale of this machine.

The Hoffman-Moore Automobile Co., Lafayette, Ind., have opened a garage and salesroom on Main street, between Eighth and Ninth. The company is composed of Samuel C. Moore, president of a local trust company, and Archie Hoffman, an automobile mechanic.

The Imperial Motor Car Co. of Canada, a recently incorporated firm handling the General Motors Co.'s lines in the Dominion, will shortly erect a new garage and salesroom building on Church street, near Richmond. The company is temporarily located on King street, and has a showroom in the Transportation Building.

The recently organized Augusta (Ga.) Automobile Garage Co. has secured a building at 729 Broad street, which will be remodeled as a garage, and occupied about October 1. The officers of the company are C. B. Garrett, Chas. D. Carr and John J. Evans. The garage is to house the cars

of members of the Augusta Automobile Association.

J. G. Klemn, Philadelphia, Pa., has let the contract for a two story 24x150 foot garage at 115 North Broad street. The contract price is \$18,000. Fred E. Gilbert, Jacksonville, Fla., has moved

from East Bay street to his new building at Laura and Church streets. Mr. Gilbert conducts a general garage business.

C. W. Foy and A. M. Hawley, Pasadena, Cal., have formed a partnership under the firm name of the Crown City Auto Repair Co., and opened a repair shop at 161 West Colorado street. They will make a specialty of Maxwell cars, with which they are particularly familiar.

O. Werner, proprietor of the Golden State Garage, located at 2122 West Pico street, Los Angeles, Cal., will make extensive additions and practically double its present capacity. Mr. Werner has recently secured the agency for Palmer-Singer cars in addition to that for the Simplex, which he already held last year.

The new eight story building of the Pence Automobile Co., Minneapolis, Minn., has been completed and opened for business. The building contains a total of 102,000 feet of floor space, and is undoubtedly the largest structure occupied exclusively by an automobile concern in the West. We expect to give a detailed description of the building in an early issue.

The garage which is being erected by J. L. Horning and John S. Hill at Fifth and Fir streets, San Diego, Cal., will shortly be completed. It will be one of the largest garages in Southern California, measuring 100x100 feet, the building comprising a 25x50 foot repair shop and a 20x40 foot showroom. It will accommodate at least seventy-five automobiles, and there are no obstructions of any kind in the main storage room.

The Corker Motor Car Co. has been organized at Atlanta, Ga., with the following officers: S. A. Corker, president; E. H. Ellerby, secretary and treasurer, and M. Z. L. Fuller, manager of out of town sales. The company, which has acquired the agencies for the Haynes and Matheson cars, is at present looking for suitable quarters. It will handle the Haynes in the States of Georgia, Florida, Tennessee, Alabama and North and South Carolina.

### New Incorporations.

Cortland Carriage and Motor Co., Philadelphia, Pa.—Capital, \$26,000.

John W. Brown Manufacturing Co., Columbus, Ohio.—Capital increased from \$75,000 to \$125,000. The Elkhart Motor Car Co., Elkhart, Ind.—Capital stock, \$200,000. W. W. Stirling is president.

Lloyd Automobile Co., Portland, Ore.—Capital stock, \$40,000. Incorporators, W. E. Cook, C. B. Lloyd and L. Templeton.

Racine Boat and Auto Co., Seattle, Wash.—Capital stock, \$30,000. Incorporators, C. W. Chandler and F. N. Mitchell.

Elmore Motor Car Co., Los Angeles, Cal. Capital stock, \$75,000. Incorporators, E. B. Smith, D. B. Rose and Clarence F. Smith.

The Worth Motor Car Manufacturing Co., Kankakee, Ill., has filed notice of an increase in capital stock from \$25,000 to \$100,000.

Western Garage, San Francisco, Cal.—Capital stock, \$10,000. Incorporators, J. E. Coombs, H. P. B. Carden and W. E. Humphreys.

The Consolidated Motor Co., Bridgeport, Conn.—Capital stock, \$5,000. S. T. Valic, president and treasurer, and E. K. Roberts, Jr., treasurer.

Hodge-Pemberton Auto Co., Fort Worth, Tex.— Capital stock, \$10,000. Incorporators, J. T. Pemberton, C. T. Hodge, B. H. Martin and others.

The Badger Auto Co., Oshkosh, Wis.—Capital stock, \$50,000. Incorporators, M. L. Cotrill, L. J. Monahan, J. D. Termaat and E. H. Fahrney.

Hinton Automobile and Supply Co., Hinton, W. Va.—Capital stock, \$2,000. Incorporators, C. C. Coalter, John Leslie, C. W. Duroin, W. H. Garnett and W. L. Fredeking.

Beverly Garage. Staunton, Va.—Capital stock. \$25,000. Incorporators, M. W. Mercereau, president; L. A. Beck, secretary and treasurer; J. S. Pancake, John H. Bowman, C. P. Bowman and L. S. Bowman.

L. S. Bowman.
The Viking Co., Kittery, Me.—Capital stock,
\$10,000.
Incorporators, H. Mitchell, president;
\$1.
J. Morrison, treasurer.

Automobile Sales and Supply Co., San Antonio, Fex.—Capital stock, \$20,000. Incorporators, Sidney H. Weis, E. A. Kalkhurst and Rover Campbell.

The Conduitt Automobile Co., Indianapolis,

Ind.—Capital stock, \$10,000. Incorporators, Wm. A. Conduitt, John A. Boyd and A. J. Cochran. Auto Spring Repairer Co., New York City.—

Capital stock, \$20,000. Incorporators, Julian M. Pinkney, Wm. R. Petze and Francis M. Pinkney. The Dayton Auto Top Co., Dayton, Ohio.—Capital stock, \$10,000. Incorporators, J. B. Kline J. P. Jeskson, Chee T. Cavilla Lorenth

Kline, J. P. Jackson, Chas. T. Cutlip, Jeremiah C. Chase and D. G. Harmen.
Eddy-Sherwood Carriage and Motor Co., Bridgeport, Conn.—Capital stock, \$5,000. Incorporators, Henry M. Sherwood, Fairfield; Geo. E. Eddy, Bridgeport, and Geo. S. Jennings, of Southport.

The Auburn Motor Garage Co., Milwaukee, Wis.—Capital stock, \$6,000. Incorporators, Harry F. Melius, Chas. G. E. Weinert and Jacob Melius, Jr., to handle the Auburn and operate a garage.

#### Trade Personals.

Wm. T. White has been appointed general manager of the Mercer Automobile Co., Trenton, N. J. William L. Scribner, formerly of the E. R. Thomas Motor Co., Buffalo, has joined the engineering department of the R. L. Morgan Co., Worcester, Mass.

J. B. Sperry, formerly of Cleveland, Ohio, has become sales manager of the Motor Car Co., of Washington, D. C., who handle the Chalmers-Detroit car in the District of Columbia.

David C. Herstine, formerly superintendent of the repair department of the Automobile Club of America, has taken the position of head instructor of the Stewart Automobile Academy of New York.

L. B. Hubbell, formerly head of the engineering department of the Pope Manufacturing Co., Hartford, Conn., has assumed the position of chief designer for the Matheson Motor Car Co., Wilkes-Barre, Pa.

We are informed that Conrad A. Dieterich, who specializes in patents and patent litigation affecting the automobile and allied industries, has retired from the firm of Straley & Hasbrouck, and has removed his office from 257 Broadway to 45 Broadway, New York city.

Wilhelm Opel, the head of the firm of Adam Opel, of Russelsheim, Germany, and Mra. Opel arrived in this country last week on the steamer Kaiserin Auguste Victoria for a six weeks' trip through the United States. Mr. Opel was the winner of this year's Prince Henry Tour.

Walter Cather, formerly purchasing agent for the Auto Vehicle Co., Los Angeles, Cal., has resigned his position with that company to engage in the manufacture of wind shields, as a member of the firm of Parish & Cather, which is located at 201 East Seventh street, Los Angeles, Cal., and manufactures the Tabor wind shield.

James C. Howell, of New York, has been appointed assistant manager of the Warner Instrument Co., of Beloit, Wis., to succeed Alfred S. Koto, resigned. Mr. Howell is a graduate of Columbia University, '94, and Columbia Law School, '99, and for two years has been in business as building contractor at Cornwall-on-the-Hudson.

# Selden Patent Sustained.

Judge Hough, of the United States Circuit Court of New York, on Wednesday, September 15, handed down a decision upholding the Selden patent in the case of the Electric Vehicle Company and George B. Selden vs. the Ford Motor Company, C. A. Duerr & Co., the O. J. Gude Company, John Wanamaker and others, and also in the suit of the same complainants against the Panhard & Levassor Company, Andre Massenat and Henry and A. C. Neubauer. These suits have been pending since 1903 and 1904, respectively. Judge Hough holds that the first claim of the Selden patent is the most important, and that both defendants are infringing it. The Selden patent expires in 1912, and has therefore three more years to run. It is very likely that an appeal will be taken by the defendants to the Circuit Court of Appeals. The complete decision and a review of the very important case will appear in our next issue.

In connection with the decision Mr. Ford, of the Ford Motor Company, one of the defendants, wishes to state that this is only the first decision in the lowest court, and that, of course, the case will be appealed to the higher court. It will be fought to a finish. It will be a matter of a few years before the final settlement of the case.

# MOTOR VEHICLE PATENTS

# Reviews of Specifications.

925,528. Pneumatic Brake for Motor Vehicles.—Ernest E. Sweet, of Detroit, Mich., assignor to Cadillac Motor Car Company, of Detroit, Mich. June 22, 1909; filed January 11, 1908.

According to this invention, the motor is used for braking the car by suitably altering the action of the valve gear. The motor employed is of the type in which both the inlet and exhaust cams are carried by the same cam shaft. The latter is arranged so as to be slidable lengthwise and is connected by means of a sliding coupling and link connection to a foot lever convenient to the driver. The inlet valve cam is of the usual construction, but the exhaust valve cam is of stepped construction, comprising four separate steps of different sections. When the motor is operating under normal conditions the inlet valve cam is located underneath the inlet valve push rod, and the section zz of the exhaust valve cam is underneath the exhaust valve push rod. If it is desired to have the motor act as a brake, the cam shaft is shifted in

the direction of its axis, whereby the inlet cam is moved from underneath the inlet valve so it will no longer open that valve, and at the same time section yy of the exhaust valve, which is shown in cross section in Fig. 3, is brought underneath the exhaust valve. The effect of this adjustment is that the engine acts as the dashpot during a portion of what would correspond to the suction and the compression strokes in normal operation. A further motion of the cam shaft brings the section xx of the exhaust cam underneath the exhaust valve. The engine will then operate as a dash-pot during the entire suction and compression stroke, but not during what would correspond to the power and exhaust strokes in normal operation. A still further motion of the cam shaft brings the section ww of the exhaustcam in line with the exhaust valve, and the engine then acts as a dash-pot all the time. Thus the braking effect of the motor is increased stepwise.

925,543. Vehicle Brake.—Joseph H. Wesson, of Springfield, Mass. June 22, 1909; filed June 30, 1908.

This invention relates to a construction whereby an internal expanding brake and an external contracting brake both act on the same drum secured to the rear wheel hub. To the housing of the rear axle is secured a stationary disc with peripheral

projections at diametrically opposite points. Into one of these projections is secured a stud parallel with the axis of the rear axle on which the two halves of the external contracting brake bands are pivoted. The free ends of these brake bands are provided with outwardly extending lugs, and to the outer faces of these lugs are secured hardened steel face cams. A stud or pin extends through these lugs and the cams, and bars are passed through slots in this stud just outside the face cams.

The internal brake construction consists of a number of blocks moving in guides secured to the axle housing. These blocks

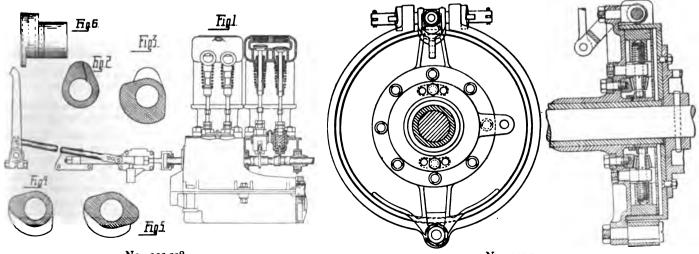

No. 925,937.

are provided with internal screw threads and have studs screwed into them which carry small bevel pinions on their inner ends. These bevel pinions mesh with a bevel gear crown which connects with a ring on the outer side of the stationary disc which encloses the internal brake mechanism. This outer ring is provided with a lever arm and may be moved through a certain angle around its axis, whereby the bevel pinions are rotated and the brake blocks are forced inward or outward, according to the direction of motion.

925,937. Elastic Vehicle Tire.—Charles Motz, of Akron, Ohio. June 22, 1909; filed July 31, 1908.

This tire is of the clincher type and of so called bridged construction. The tread of the tire consists of laterally extending portions between which there is a depression. The lateral extensions arch outwardly, which permits to spread them widely to form a very wide tire, giving a large gripping surface; but in order to further increase their gripping effect cross webs or bridging pieces are located at in-

No. 925,528.

No. 925,543.

tervals within the depression on the tread. As another means of increasing the gripping effect, the tread of the tire is provided with peripheral bead sections formed integral with the tire, the beads on one tread portion being opposite the space between beads on the other tread portion. The beads are semi-cylindrical in cross section and are formed integral with the tire. In order to increase the resiliency of the tire, the laterally extending portions are undercut, and the extensions are supported by inclined webs. Under pressure these webs bend and flatten, and they may be made sufficiently thick to insure strength without destroying their resilient effect. It is stated that it has been found that by inclining the webs the disintegration of the rubber is to a great degree eliminated, and a greater length of flexibility is secured.

926,330. Electric Ignition Device.—Theodore Hubert, assignor to Charles F. Splitdorf, New York, N. Y. June 29, 1909.

The novel feature of this device is the means for advancing and retarding the spark. The armature shaft is provided with a spiral groove in which a pin or projection attached to the sleeve 26 is adapted to slide. Collar 35 is the driving means, receiving a rotary motion from the engine, and having internal grooves engaging projections (not shown) in sleeve 26, which transmit rotary motion while permitting a longitudinal or axial motion of the sleeve. The adjusting arm 27 carries pins 31, projecting into oblique slots in a stationary sleeve attached to the magneto frame. Any

No. 926,330.

rocking motion of the arm produces, through the action of these pins and slots, a longitudinal motion of the arm which is communicated through the annular ball bearing to sleeve 26, the inward projections of which, in turn, cause a partial rotation of the armature shaft with relation to the collar 35, with a corresponding alteration in the time at which the spark occurs.

# The Horseless Age

First Automobile Journal in the English Language

VOLUME XXIV

NEW YORK, SEPTEMBER 22, 1909

**NUMBER 12** 

# Dependence of Tire Life on Wheel Diameter and Cross Section.

BY ALBERT L. CLOUGH.

It is pretty well admitted upon all sides that there is a decided economic advantage in the use of pneumatic tires of larger cross section than that which is barely necessary to carry the weight of a car without frequent blowouts. That is, that if a 4 inch tire can be used to support so many hundred pounds of car weight, and come within the recommendations of the tire makers, a 41/2 inch tire can be employed with even greater ultimate advantage, for the larger tire, although costing more initially, may be expected to afford so much additional mileage as to reduce the tire bill per mile to a lower figure than that obtainable with the smaller one.

Another belief which is widely held is that, assuming two tires of the same cross section, say 4 inches, one of them 30 inches in diameter and the other 36 inches in diameter, the latter is the better proposition economically, assuming that both are used under cars of equal weight, horse power and speed, with suitable differences in their driving gear ratio.

The writer knows very little, indeed, about the tire problem, and does not remember ever seeing any figures published giving a concrete idea of how two such cases as the above figure out from the economic standpoint. This little communication is written in a spirit of inquiry, in the hope that it may bring out some pertinent information from the tire makers, from car manufacturers or from users. As far as the average motorist is concerned, the answer to the question as to whether the large diameter tire is cheaper in the end than the small diameter tire of equal cross section, conditions of use being the same, is almost entirely a matter of opinion, unsupported by accessible data.

## LARGER WHEEL DIAMETERS.

It would be interesting to know what bearing, if any, the following considerations have upon the question: Take the case of two cars, otherwise of the same model, one equipped with 30 inch wheels and 4 inch tires, and geared 3 to 1, and the other fitted with 36 inch wheels and 4 inch tires, and geared 3.6 to 1. These two cars should possess the same speed and hill climbing power. Under these

conditions the tractive effort exerted upon the road by each tire is obviously the same, and each section, as it becomes the point of contact, is equally stressed. In the case of the 36 inch tires, however, each section is thus stressed only 5/6 as frequently as in the case of the 30 inch tire, at the same car speed. In so far as this oft repeated stress upon the structure of the shoe tends to disrupt it, it would seem that the larger tire should have the advantage in point of length of life.

If the two cars possess equally powerful brakes, the stresses in the tires due to brake application are of equal severity in both cases. Exactly as in the case of driving stresses, the frequency with which any one section of the casing is stressed, in retarding the car, is only 5/6 as great in the case of the larger as in that of the smaller tire. Has anyone any data as to the practical effect of these different rates of repetition of these stresses?

### SLIPPING.

The attrition between the road and the tire, tending to wear away the tread, is distributed over 6/5 as much surface in the case of the larger tire as in the case of the smaller one, the presures and sliding stresses being roughly the same in the two cases. The larger tire has a larger area of contact with the road than the smaller one, however. Does this make any difference in the rate of slip in favor of the larger tire? If so, is there any difference in the rate of wear of its tread due to this cause? It is frequently assumed that, between surfaces of the same materials, equally loaded, friction is independent of the area of the contact surfaces. Is this rule true when applied to tires?

If the rate at which the materials of the shoe are fatigued by the driving and braking stresses imposed upon them, and also the rate at which the tread is worn down are, as they would appear to be, 5/6 as rapid in the case of the larger tire as in that of the smaller, this is only another way of saying that these rates of failure are inversely as the amount of material in the two sizes of tire, the cross sections being equally heavy in both instances.

It is understood, however, to be the practice with many tire makers to employ additional layers in the building up of the 36x4 inch tire section as compared with those used in fabricating the 30x4 section, and that there is also some additional rubber in the 36x4 tread. Certain makers, on the contrary, seem to use identical sections for all tires of the same cross section, irrespective of wheel diameter.

## EFFECTS OF ROAD IRREGULARITIES.

Considering the effect of road irregularities upon these two tires, it is evident that, in absorbing a rock or other obstruction upon the roadbed, the wall of the large diameter tire is required to flex less abruptly than the wall of the smaller one. The question as to how much, if any, significance this fact has as tending toward a longer period of service in the case of the larger tire is an interesting one, and one probably incapable of prediction on a priori grounds, but requiring experimental demonstration.

Road shocks due to the wheels dropping into road depressions or climbing abrupt water bars are admittedly less in the case of larger than that of smaller wheels. Assuming springs of equal efficiency on the two cars which we have been considering, and admitting that the oft repeated action of pneumatic tires in absorbing road shocks is one of the most important, if not the most important, causes of their ultimate failure, what effect may a difference in diameter between 36 and 30 inches have in the life of the two sizes of tires here taken as examples?

## RESILIENCE OF WOOD WHEELS.

Another question may be worth the asking. Does the resilience of the wood wheel itself act in an appreciable degree to mitigate the severity of the shocks borne by tires? If so, is the 36 inch wheel, with its longer spokes, an appreciably more efficient aid in "buffing" the shocks than the 30 inch wheel, and thus a factor in the direction of longer tire life? It may be that this is a question worth considering in connection with dished spokes, but not with the ordinary form of wheel.

Referring to a 1910 price list of tires one finds the 36x4 tire and tube listing for 21.7 per cent, more than the 30x4, while the diameter of the 36 inch tire is exactly 20 per cent, greater than the 30 inch.

The prices are thus very nearly in proportion to the diameters, and the economic advantage of the larger tire, if there be any, may be found in the extra heavy cross section and tread sometimes embodied in the larger diameter tire, in its less susceptibility to damage by shocks due to road irregularities, and the greater ease with which it absorbs rocks and other objects. The writer would very much like to know whether practice demonstrates any such advantage to exist, and the magnitude of it.

#### OPTIONS PUZZLING.

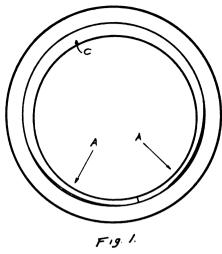

This question was brought up recently by a party who was contemplating buying a chassis from a manufacturer who offered an option in regard to wheel diameters, including the 32, 34 and 36 inch sizes. After discussing easy riding qualities, centre of gravity and so forth, the query arose as to which size would afford lowest tire maintenance cost. No reliable data could be obtained at the time to settle this point. As there are probably other readers who have had the same question come up in their experience, the matter is brought up here in the hope that some light may be shed upon it.

Referring to the point touched upon in the first paragraph of this article—that of the economic value of tire sections with a large factor of safety as regards weight carrying capacity—it is probable that definite figures from users who have employed tires of different section upon the same car at different times, as to the magnitude of the advantage gained by using the larger ones, would be very welcome, as no published figures upon this subject are recollected.

# Piston Packing Rings. By R. M. A.

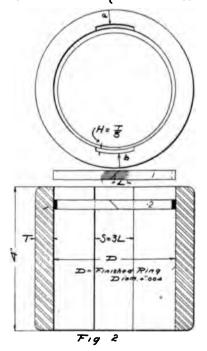

So far as the machine shop can lessen the cost both of hand labor and of a "running in" of bearing parts, it is not only reasonable but economical to do so. This preliminary leveling of high spots and a consequent longer life to the motor without adjustment is a live issue today. Yet at present some manufacturers are relying upon hand labor for a large part of the fine fitting that can be disposed of in the machine end. Pistons and their rings are still being filed after leaving the grinder, thus destroying a good surface and increasing expense.

It has long been noted that the points of the piston packing rings project with sufficient force to prevent the immediate vicinity back of these points from bearing. This is so marked that with a ring, as it is finished in many shops, held in a standard gauge bushing, this lack of bearing allows light to pass through (see Fig. 1, AA). This space allows compression to leak by, as well as oil to waste. Placing two similar engines side by side, with a maximum oil level in the crank case of engine A, having

tight, well fitting rings, and a minimum level in engine B, with poorly fitting rings, it was difficult to cause A to smoke as much as B. A had stiff rings that fitted well from the first; with B the case was the very opposite. It was also noted on all engines of type A that the road testers wondered at this apparent lack of oil, having become accustomed to its prevalence at the exhaust pipes of the B type. In general, no hand filing was done or found necessary after the proper manner was found for machining the rings of A.

If in Fig. 1 the points of the ring C bear so hard as to sacrifice part of the bearing surface, it is logical to reduce these high spots, as previously done with a file. To do this in the lathe was even simpler. It is the general practice to house the rings in a hardened bushing preparatory to clamping them on the flanged arbor for the final cut. This bushing, however, was simply relieved by cutting two channels diametrically opposite, and the rings were placed in as before, but alternating their relation, the gap of ring No. 1 coming directly over the heavy part of No. 2, and all points opposite

either one channel or the other. Fig. 2 shows this plainly. The rings, on being clamped on the flanged arbor, with the bushing removed, have their points perceptibly projecting beyond the adjacent rings, such that in cutting the tool removes proportionately more metal at these points. The strength of metal here is now sufficiently reduced so that the ring as a whole has a more uniform bearing. For average practice the width of channel S=3L, where L is the average length of the high spot (see L, Fig. 2). The length L should preferably be taken from a regular old style shop ring after same has been run in a regular test before shipping. The depth of the channel

S is taken as  $H = \frac{T}{5}$ , where T is the thick-

ness of the steel bushing, which latter should be at least one-half inch. To space the ring points equally over the channel S two fine file marks are cut at a and b so that when the ring is flush in the bushing the upper edge of the gap is in line with its respective mark. In filling the bushing with rings care should be taken to give them a motion parallel to the axis of the bushing, as any twisting will tend to dislocate the ring.

With a more perfect bearing of the ring assured the "stiffness" of the same rings can be reconsidered. There being no theoretical compression radially, the strength of the ring is unaffected by either compression or explosion. When we consider the very light springs used on large steam cylinders to keep the ring bearing, it seems true that many of the present designers have made the gas engine ring stiff in order to insure its wearing in properly. An instance of rings that were too severe is very interesting and baffled the designers at first.

Three very stiff rings were used all at the top of the piston. The men complained of their difficulty in pushing the piston up into the cylinder. This was the first real notice we had. On examining the cylinder after a short run it was found that all traces of the grinder had been removed in the path of the rings only. A few cars were shipped with these rings, and it was not long before customers complained of a peculiar knock in the motor. After trying all past remedies (of course not as yet knowing the cause) with no results, the motors were torn down. Ridges were found in the cylinders corresponding exactly to the path of the rings, but on the opposite side from the thrust of the piston. New cylinders being tried, the trouble disappeared, and, having substituted lighter rings, the trouble has not recurred. The interesting part of this is that the perceptible wear was on the opposite wall from the thrust. This can be explained only by the fact that the thrust caused the piston and the rings to bear or the wall, while on the opposite wall the rings projected a distance equal to the clearance of the piston diameter and cylinder such that the rings acted like cutters and "pulled down" this wall.

# Heat Distribution in Auto Engines. By F. E. WATTS.

The article on page 231 of the issue of September 1, entitled "Fuel Economy and Its Dependence on Engine Design," sets forth in an admirable way many of the conditions which must be met to secure economical operation. The advantages to be secured by making the walls of the compression space of as small area as possible in relation to its volume are, however, perhans overemphasized for automobile work. Probably there is less heat lost from an engine with a nearly globular compression space than from one having any other form; but the difference is not great enough to warrant the importance usually given to the matter in text books, at least not for small engines making a large number of revolutions per minute. When I first began work on stationary engines I believed in long stroke engines for this very reason, but was never able to definitely trace any increased economy to the use of a long stroke. The long stroke engines wore better and ran more quietly as a general rule. but were not markedly more economical of fuel.

The only really important reason why a long stroke motor should be more economical than a short stroke one, aside from frictional considerations, is that the charge is retained in the cylinder longer, and hence each particle is liable to be more completely burned. There is probably little difference in the heat lost through the cylinder walls, no matter what the ratio of bore and stroke, at least for small engines.

Let us consider two engines, A with bore and stroke of 4 inches each, B with a bore of 4 inches and a stroke of 8 inches. Their data might be as follows:

	A.	В.
Piston displacement	50 cu. in.	100 cu. in.
Revolutions for 1,000		
feet, piston speed	1,500 r. p. m.	750 r. p. m.
Compression space	15 cu. in.	30 cu. in.
Time of stroke	0.02 sec.	0.04 Sec.
Expansion ratio	Same in	both.
Expansion rate	2	1

This table shows that there will be little difference in the heat losses in the two engines. B takes in twice as much gas as A, and handles it in a chamber which has less wall area per unit of charge than A, but it handles each unit slower, expands it for a longer time, and hence exposes each unit to the walls for a longer time.

As was stated in the article before referred to, the cylinder temperatures and pressures fall rapidly after the charge begins to expand, and hence the heat loss to the walls is greatest at the beginning of each stroke when the exposed surface consists of the walls of the compression space, the piston head and the upper part of the cylinder bore. But the diagrams for the heat transferred to the walls and for the heat transferred from the walls to the water jacket could they be drawn, as they no doubt will be in the near future, are not at all like the diagram for the heat inside the cylinder. The heat loss to the walls

no doubt varies greatly in different parts of the cylinder with different methods of applying the cooling agent and with various arrangements of the valves. Convection of the gases and heat transfer from the piston are the two important factors which tend to equalize the cylinder temperature and heat losses per unit from the top downward.

This is admirably shown for a small motor by the experiments of Prof. H. L. Callender, which were described in THE HORSE-LESS AGE of May 18, 1904. The motor was a Clement Garrard cycle motor, with a single vertical, air cooled cylinder. The bore was 2.4 inches and the stroke 2.8 inches. Circumferential ribs were used for cooling, as shown in the sketch. The compression was 68 pounds at 730 r. p. m. with full throttle, and 33 pounds at 1,160 r. p. m. with

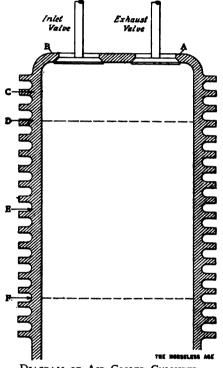

DIAGRAM OF AIR COOLED CYLINDER.

small throttle. Temperatures of the cylinder walls were measured at various points by means of thermo couples screwed into small holes in the walls.

When the motor was run on the block the temperature near the exhaust valve, as at A, rose to 570° C. So a centrifugal fan was mounted on the flywheel so as to deliver air horizontally across the head. A second fan was arranged to deliver air horizontally against the side of the cylinder. When only the first fan was used the temperature at A rose to about 400° C. With both fans it rose to about 300° C. At B it rarely rose above 70° C. On the walls of the combustion chamber, as at C, it was from 200° to 260° C. Tests at D, E and F showed a drop of only about 20° C. in the length of the stroke. That is, when the temperature was 200° C. at D it was 180° C. at F. Furthermore, it was found that retarding the spark raised the temperature

of the head and lowered that of the barrel.

The manner of cooling this motor was not favorable to the transfer of heat downward, but evidently on account of its high speed, 2,000 r. p. m. in some cases, the piston carried heat enough to the lower end of the cylinder so that the heat lost per wall unit there must have been quite large, as compared with that through the walls of the compression space. Very likely in slower running, water cooled automobile engines the piston convection is less, but it has been shown to be considerable even in large stationary engines.

For these reasons I believe that while the shape of the combustion chamber is of importance, it has less influence on engine economy than is generally thought. And while valves in the head, cylindrical or globular compression spaces, and long strokes have their advantages, they are not important enough to warrant their preference over other forms of construction. They aid in more thoroughly scavenging the cylinders and in taking advantage of gas inertia, and these advantages will probably eventually be considered of more importance than their as yet undetermined influence on heat losses.

# A Home Made Automobile Fire Extinguisher.

By J. M. PRUDDEN.

It is remarkable how few automobiles are provided with some sort of fire extinguisher, although the value represented by an automobile and the chances of fire are very great. This may be due to carelessness of the owners, it may be that the price is a deterrent, or even the appearance may be against the extinguisher. If the car should ever catch fire on some country road far away from water or help this neglect would certainly be deplored. The appearance is a small matter, for modern extinguishers are neat, and as for the pricewhy, it is the possible saving of money which would prompt you to get one. No matter how good a car may be, it is liable at any time to catch fire. No matter whether your car is insured or not, a fire may endanger life.

The principal difference between the two types of extinguishers, one using liquid chemicals and the other powder, is in relation to prices. Although the powder may not be so easily sprinkled in inconvenient places as the liquid may be sprayed, there is advantage in the powder in that it will not spread burning gasoline or oil, which are often the source of automobile fires, and, of course, the powder cannot freeze, as the

liquid might.

The modern fire extinguishers contain about 10 cents' worth of tin and 25 cents' worth of chemicals, and sell for \$2. By following the directions given below anyone can easily construct a fire extinguisher, even of brass, for less than \$1. At any plumber's a piece of 11/2 inch tin leader pipe may be procured, about 2 feet long. (This can easily be made from 24 gauge sheet brass.)

A bottom should be made and strongly soldered on, and the edge of the open top end turned over. Then a cover should be made which will fit tightly, and which should have a ring riveted to the top of it. The tube should then be filled with carbonate of ammonia (which can be procured cheaply at any drug store, and which should

SKETCH OF FIRE EXTINGUISHER.

be exposed to the air as little as possible), the cover put on and pushed down firmly. Since this chemical must be kept from contact with the air, in the manufactured extinguishers a very thin layer of solder is placed around the edge of the cover, rendering it airtight and yet leaving it so that it may be easily yanked off. It is not possible to solder with ordinary tools as thinly as is necessary, so sealing wax may be placed around the cap instead. In case of fire it is merely necessary to attach the ring in the cap to something, yank off the cover and sprinkle the powder on the fire.

It is surprising what a large fire this extinguisher will put out. It can overcome a fire covering 9 square yards and blazing nearly 15 feet high. It may be attached to a car by a strap or some similar device, but it should not be hung by the ring, for the jarring of the machine would break the sealing wax, decomposition would ensue from contact with the air, and the chemical would be worthless. If this extinguisher were made of brass and placed on the running board of a car it would be no more unsightly than a musical horn.

# Amount of Radiator Capacity Required.

BY ALBERT L. CLOUGH.

Although much experimental work has been done to determine the amount of heat which can be abstracted from a given extent and configuration of radiator surface by a current of air of given speed and initial temperature, when there is circulating within the radiator passages a current of water at a known initial temperature, the proportioning of a radiator adequate to cool a motor of given proportions is still pretty largely of an empirical nature rather than a matter of exact calculation.

Motor car manufacturers now hardly ever construct their own radiators, for the reason that the production of this auxiliary of the vehicle engine has been taken over by a number of manufacturers who devote their energies almost entirely to this specialized line of production, which they have brought to a high degree of refinement.

## THE USUAL PROCEDURE.

When an automobile manufacturer is bringing out a new model with a motor somewhat altered in dimensions and characteristics from that which he has hitherto used, experience as to the sizes of radiator required in former models is usually the basis of the specifications for the experimental radiator to be used upon the "model car" of the new product. A radiator is ordered, a certain amount larger or smaller than the one used upon the former car, and this is tested out thoroughly upon the new vehicle, and if satisfactory may be adopted. If not, a cooler of somewhat difierent dimensions is secured, and this is tested out in the same way. Or the manufacturer may furnish the radiator builder with a full description of the new motor and the new car, and the latter furnishes a radiator for test, which, if satisfactory, is adepted. Suggestions as to the fan design pipe sizes and pump capacity, are often made for the car manufacturer by the radiater maker.

# DATA GATHERED.

The writer recently took some pains to look up the subject of the dimensions of

the radiators fitted upon 1909 models of standard cars. These radiators comprised a considerable number of different makes, and included the true cellular and various forms of horizontal and vertical tubular types. The cars upon which they were used were equipped with four cycle, four and six cylinder motors of widely varying bore and stroke.

The number of cars studied was quite large. In each case the piston displacement of the motor in cubic inches was computed, and the whole volume of the active portion of the radiator (not including the tanks) was figured, and it was a matter of some surprise that the cubic inches of radiator volume per cubic inch of piston displacement as computed for these various cars showed no wider variations among themselves. It appears, in fact, that the space occupied by the radiating surfaces required to take care of the heat loss attributable to a cubic inch of piston displacement shows a decided tendency toward constancy, despite wide variations in the magnitudes of the two variables, and in the form of the heat dissipating surfaces.

## CYLINDER-RADIATOR VOLUME RATIO

The average number of cubic inches of cellular radiator allowed upon these cars per cubic inch of piston displacement figures about 4.25. and the average cubic inches of tubular radiator per cubic inch of piston displacement appears to be about 4.5.

It is perhaps rather surprising that there is so little difference in the space required by the two types, but it is pretty evident that the makers of the various radiator types have worked their respective designs to closely corresponding extremes of "volume efficiency," and it would appear either that the tubular type is about as effective as the cellular, or else that the users of the cellular type have been more liberal in their cooling provisions.

A provision of much less than 40 cubic inches of radiator volume per unit of cyl-

inder volume is decidedly uncommon, as is also the allowance of much over 5.0 cubic inches, despite great variations in the absolute dimensions of engines and of the radiators themselves.

The extreme thickness found in any of these radiators was 4 inches, and this value was reached only in the cases of a few large cars, where it was undesirable to further increase the frontal dimensions.

#### PUMPS AND FANS.

All the radiators whose dimensions were taken were provided with fans, and the circulation was by pump. A high speed of flow-seemed generally to be provided for, and the flow pipes were of good size. A half inch of cross section for each 6 horse power motor output is recommended by some radiator manufacturers.

Each radiator maker appears to adhere rather closely to a certain size and form of pipe, and thickness and spacing of fins, in building up his cooler, and the capacity of the radiator is generally altered by using a greater or less volume of this standard construction, cut to fit the bonnet lines of the car to which the radiator is to be fitted. It is this fact that gives to the "cubic inches of radiator per cubic inch of piston displacement" constant what little value it may possess in rough preliminary calculations. There is not necessarily any exact scientific basis for this criterion, although it is perhaps not easy to formulate a better one of equal simplicity, especially as comparative figures concerning the active exposed surface of different makes of radiators are rather jealously guarded by their manufacturers.

It is probably safe to say that any radiator of standard make, which is assisted by a fan proportioned in accordance with average 1909 practice, and through which water is properly pump circulated, will be on the safe side, as far as cooling surface is concerned, if it contains 5.0 cubic inches of volume for each cubic inch of piston displacement of the four cycle engine which it cools.

# FOR THERMO-SIPHON CIRCULATION.

Most radiator manufacturers explicitly recommend radiators of much larger size for use with thermo-siphon circulation—50 per cent. or more increased surface in some cases. Not enough data upon radiators operating upon this system has yet been gotten together to enable an empirical constant to be calculated. In a few cases of thermo-siphon cooled engines, which have come to the writer's notice, however, the provision of radiator volume is hardly any, if at all, more liberal than in cases where pump circulation is used.

As to the use of fans, many radiator manufacturers assert that their use is valueless, if not undesirable, except when the car is standing or at speeds below 15 miles per hour approximately, on account of the practical difficulty of producing an air suction equal to the natural air pressure drive to higher rates of motion.

# THE HORSELESS AGE

9-15 Murray St., New York.

Every Wednesday.

### The Selden Decision.

The decision of Judge Hough, upholding the Selden patent, constitutes a decided victory for the owners of the patent, the Electric Vehicle Company, and also for the Association of Licensed Automobile Manufacturers. The owners of the patent had triumphed over alleged infringers several times previously, as when the Winton demurrer was overruled, and when an injunction was issued against one Moore who failed to put in a defense, but all these successes count for little in comparison with the decision just rendered. In none of the former suits was the validity of the Selden patent put to an actual test, and it was a very prevalent opinion in the industry that it would not successfully withstand such a test. In fact this belief was so strong in recent years that the possibility of being compelled to pay royalties under the patent would have been laughed to scorn by many unlicensed manufacturers.

Now, however, the patent has stood the test. One of the best known judges of the United States Circuit Court, widely experienced in patent litigation, has declared it to be valid and legal, and to cover all forms of gasoline automobiles. Of course, as was

to be expected, this decision is not final. The interests involved are so large that the case will be carried to the highest court, and there is, of course, a chance of the present opinion being reversed by the courts, as has often occurred in the past. But it is obvious that the case of the complainants has been greatly strengthened by the present decision.

Judge Hough points out in his opinion that the granting of the patent by the Patent Office already raised a presumption in favor of the complainant, and the Winton demurrer decision, which was a controlling authority, to the effect that on its face \* \* the patent was valid, strengthened this presumption. Now these points in favor of the patent have been further added to by a decision holding it valid after a most prolonged legal battle in which apparently every vulnerable point was subjected to attack.

The decision provisionally establishes George B. Selden as the real inventor of the gasoline automobile. Selden may not have been the first to build a successful machine, but he is considered the first to correctly name all the essential elements of such a machine. The lustre which might thus have been conferred on Mr. Selden is somewhat dimmed, however, by Judge Hough's remark that "it is my belief that Selden had contributed little to motor car advancement in the United States, and nothing at all abroad."

However, the most important question raised by the decision is not one of credit for priority in invention, but a question of commercial control of the gasoline automobile business. The members of the Association of Licensed Automobile Manufacturers are, of course, not affected by the decision, because they have already recognized the validity of the patent. But if all the unlicensed makers should now be forced to pay tribute to the owners of the patent, it would not be surprising if the aggregate value of the products covered by the Selden patent during the entire time of its life were to be greater than that of the products covered by any other patent during a corresponding period. Although the royalties will probably be fixed at a low percentage, the amount will, no doubt, run far into the millions. As nearly as can be ascertained about 300,000 cars have been manufactured in this country to date. Of these about one-half, or 150,000, have been licensed under the Selden patent. The average value of the cars on which royal-

ties have not been paid may conservatively be placed at \$1,000, giving an aggregate value of \$150,000,000. The royalty originally paid by American manufacturers was 1½ per cent., and this percentage of the above amount figures out to nearly \$2,000,000. Present prospects would make it seem well within the limits of possibility that the royalties on the above basis on the cars that will be manufactured during the remainder of the life of the patent may reach \$5,000,000.

As we understand the matter, there are still a number of legal steps to be taken before the present case is definitely concluded, and then the owners of the patent will be in a position to propose terms to manufacturers who are not yet licensed. It is generally believed that no higher royalties will be exacted, at least not for cars already delivered by the manufacturers, than those which have already been fixed by the association. Unlicensed manufacturers who are not willing to meet the demands for royalty, if sued, may be able to secure immunity from injunction proceedings pending the trial of the case in the higher courts by putting up bonds. In any case the decision will probably have a rather disturbing influence on the trade and industry, tending to bring back the condition of uncertainty which prevailed shortly after the organization of the "Licensed" Association in 1903, and it is to be sincerely hoped that the owners of the patent, as soon as possible after the decree has been rendered, will come forward with a definite statement of policy, so that every manufacturer will know exactly where he stands, and the market will not be disturbed by frequent injunction threats.

## Maintaining Quality.

Perhaps the most difficult problem which confronts a company entering on the manufacture of automobiles is the question of how to keep the quality of their cars uniform, so that each car they turn out shall approach the standard which they believe desirable, or possible, for a car of that particular class.

Quality maintenance may be roughly divided under three heads, viz., maintenance of the quality of the material, maintenance of size and finish, and maintenance of a predetermined accuracy in assembly and adjustment.

The manufacturer can enforce his standards under each of these heads by specifications, inspections and tests. Fach of these

three methods of maintaining quality can be elaborated as much as is thought desirable. Thus the specifications given in an order for material may vary all the way from a plain order for so many pounds of "30 carbon" or "nickel" steel, through specifications which seek to maintain the quantity of each element in the steel between certain limits, through others which also specify physical properties which the metal must exceed, to those which in addition to the last take up the manufacture of the metal, and perhaps even the quality of the ore.

Naturally the more rigorous the requirements of the specifications the higher is the price of the metal, and the more frequent must be the tests and analyses to make sure the quality is maintained.

In the machine shop the sizes of each finished surface are usually specified on the drawings, together with the amount of variation from this ideal size which is allowable. The necessary quality of the surfaces is not usually specified, but is left to the judgment of foremen and inspectors.

Just what the limitations of size should be for any piece of work is a much discussed question, and long experience in manufacturing and assembling is needed in deciding on limits. It seems probable, however, that too close fitting should be avoided on most parts, and that a rather liberal allowance with the standards carefully maintained often gives better results as regards quiet and regular operation than does an allowance which is so small that it is not enforced by the inspection department. Limits which are so close that the shop cannot live up to the requirements usually tend to create friction between the manu-. facturing and the inspection departments, and often result in compromises and agreements in utter disregard of the figures on the drawings.

Close fitting of bearing parts usually makes a machine more expensive, but with the exception of a few hard worked bearings does not always make the machine more efficient. With regard to the spacing of centres for working parts and the alignment of attached surfaces, however, a high degree of accuracy usually results in a more efficient and quiet mechanism.

Care in the machine work and inspection usually results in reducing the cost of assembling, and the requirements of the assembling process usually play an important part in regulating the limits specified for the machine work. The accuracy of the final assembling and the care with which the car is adjusted, or "tuned up," to use a more descriptive phrase, probably play as large a part in securing satisfaction for the average user as anything we have previously mentioned.

Here, again, we find great differences in the practice of various makers. Some test the cars in the most perfunctory manner. Others test them rigidly, and every car must pass a thorough inspection, which includes the operation of every part and even the condition of small but important parts, such as the tightness of nuts and the presence of cotter pins. Naturally the results secured by these latter makers are more satisfactory to the purchaser than those of the former.

As stated at the beginning, uniform quality is difficult to maintain, but the maintenance of a fairly good quality is not nearly so difficult or costly as the maintenance of a very high quality. The question which confronts the manufacturer, then, and which is becoming more than ever important in these days of lowering prices, is: "What standard shall I seek to maintain?" At the present time there is no universally applicable answer. Probably there never can be, since the answer will very likely depend upon the class of people which it is desired to cater to. At the present time automobile work probably suffers fully as much from over-refinement as it does from careless workmanship.

There is a medium course in the writing of specifications for materials in the setting of limits on machine work, and in the final inspections and tests which will produce the most serviceable and satisfactory car at a reasonable cost. Only a few manufacturers have as yet approximated this course, but a good many of them are tending toward it.

In one respect, at least, the Selden decision came at an opportune time, and may have a decidedly beneficial effect. We are referring to its probable effect on the unchecked promotion of new manufacturing concerns. A too rapid growth has been fostered by the unprecedented demand for cars during the past year, which was largely the result of the general reduction in prices on moderate powered cars at the beginning of the season. Further reduction of prices may still further increase the demand, but it is obvious that this process of extending the market cannot be continued indefinitely, and if the present rate of expansion should

be kept up it would not be long before the supply of cars would overtake the demand, and the industry would be brought face to face with the serious problems consequent upon overproduction. If some of the numerous recent flotations should be nipped in the bud by Judge Hough's decision it would very likely be to the ultimate advantage of the industry.

# Electrically Preheated Vaporizing Surfaces.

A number of patents have recently been issued covering means for electrically heating the vaporizing surfaces around which the fuel vapor supplied to gasoline and kerosene engines is formed. The object of the arrangement is to facilitate starting under conditions of low temperature of the surfaces.

The claims cover means for supplying heat to internal vaporizing surfaces such as are employed in cylinders fed by fuel injection, and also to the surfaces of external vaporizers or carburetors. Suitably protected coils of wire or ribbon through which the currents are passed and which are arranged in suitable proximity to the surfaces to be heated are the means employed.

This application is of possible interest to motorists who house their cars in unheated stables and experience difficulty in starting their motors. The use of a torch to heat the parts is decidedly risky, and the ability to quickly heat the carburetor vaporizing chamber by connecting a heater arranged about it for a few minutes to the regular lighting circuit might prove a convenience. In fact an ordinary domestic electric heated pad or electro-therm can be used quite successfully for warming up the carburetor and the intake manifold.

# Coming Events.

September 20-22—New York, Second Annual Run Around Long Island, New York Automobile Trade Association.

Trade Association.

September 21—Riverhead, L. I., N. Y., Motor
Contest Association Meet.

September 21 to 29—Munsey Reliability Run, Washington, Boston and return.

December 29-30—Philadelphia (Pa.) Annual Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7—New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

January 8 to 15-New York Annual Show, Madison Square Garden, Association of Licensed Automobile Manufacturers.

February 5 to 12—The Ninth Annual National Show at Chicago, Ill.

# Some Points in the Operation and Care of Vehicle Batteries.

(Paper read by H. M. Beck before the Society of Automobile Engineers.)

With the rapid increase in the number ei electric vehicles, the question of the proper operation and care of the storage battery becomes one of increased importance. as the best vehicle will not run if the battery goes wrong. While under normal conditions the care of a battery is a comparatively simple matter, it must not on this account be entirely overlooked, and, unfortunately, there has been some tendency recently to minimize the actual attention required. This policy is not new, having been tried in other lines of battery work, and if continued is sure to result disastrously. Why not rather admit that a certain amount of attention is required and insist on it? The best battery can be ruined in a comparatively few charges or discharges, where it would have given a long life with proper treatment.

The instruction books furnished by the manufacturers go into the operation and care of vehicle batteries very completely, and as they have been revised from time to time, one of them now being in its sixteenth edition, they are up to date. It will not be necessary, therefore, to go into many of the details of operation, but there are certain points which are either frequently misunderstood, or else on which it would be well to lay special emphasis, as their importance has apparently not been appreciated.

A storage battery is chemical in its nature, rather than mechanical, and must not, therefore, be confused with mechanical apparatus. The latter gives much more marked warning when it requires attention, and the fact that a battery may be apparently operating perfectly when it requires attention is responsible for a great deal of battery trouble. When a battery finally breaks down permanent injury has been done, and while it can generally be doctored back into shape, it cannot be made to give the life it should have given. In probably no line of technical work is prevention rather than cure of so vital importance.

Unfortunately the chemical theory of the storage battery has never been definitely settled, but an approximate idea of what goes on during charge and discharge can be easily stated.

A storage battery from an elementary standpoint consists of two or more plates, positive and negative; insulated from each other and submerged in a jar of dilute sulphuric acid. The plates consist of finely divided lead known as the active material held in grids which serve both as supports and as conductors for the active material. The active material being finely divided offers an enormous surface to the electrolyte, and thus electro-chemical action can take place easily and quickly. Two plates such as described would have no potential dif-

ference, the active material of each being the same. If, however, current from an outside source is passed between them, one, the positive, will become oxidized, while the other remains as before, pure lead. This combination will be found to have a potential difference of about two volts, and if connected through an external circuit current will flow. During discharge the oxidized plate loses its oxygen and both plates will become sulphated until, if the discharge is carried far enough, both plates will again become chemically alike, the active material consisting of lead sulphate. On again charging the sulphate is driven out of both plates and the positive plate oxidized, and this cycle can be repeated as often as desired until the plates are worn out. Thus charging and discharging simply results in a chemical change in the active material and electrolyte, and the potential difference between the plates and capacity is due to this change.

In taking care of a storage battery there are four points which are of the first importance:

First—The battery must be charged properly.

Second—The battery must not be over-discharged.

Third—Short circuits between the plates or from sediment under them must be prevented.

Fourth—The plates must be kept covered with electrolyte, and only water of the proper purity used for replacing evaporation.

While, as already stated, it is impossible to give an accurate formula for the chemical changes which take place in a storage battery during charge and discharge, certain facts dependent upon these are well established, and are used as a basis for operation. These are the following:

Voltage—During charge the voltage of a battery gradually increases until the cells are fully charged, but it will then come to a standstill, and will not rise any higher, no matter how long the charge is continued. The maximum voltage thus reached is not a fixed point, varying widely at different times, depending upon the age of the battery, the temperature, the strength of the electrolyte and the charging rate.

During discharge the voltage falls, and if the discharge were carried far enough it would reach zero, but experience has shown that this point is much too low for safety, resulting in the rapid destruction of the plates.

Specific Gravity—Due to the fact that during discharge the active material of both plates becomes sulphated, the specific gravity of the electrolyte falls. During charge the reverse process goes on, the sulphate is driven out, and the specific gravity of the electrolyte rises. As with the volt-

age, the gravity will rise gradually during charge until all the sulphate is driven out of the plates, but will then show no further increase, no matter how long the charge is continued. The maximum gravity thus obtained is also a variable figure, depending upon the temperature of the electrolyte as well as upon the actual amount of acid and water present in the cell.

The fall in gravity is almost proportional to the ampere hours discharge. In other words, specific gravity readings can be used as an ampere hour meter, but, unfortunately, gravity readings are difficult or disagreeable to obtain in the case of vehicle batteries, so that this check on the discharge is not frequently used.

Gassing—Until nearly charged, the plates in a storage battery should absorb the energy put into them with little or no gassing. When they are nearly charged, the energy, instead of being stored, shows itself in the form of more or less gassing, the amount depending upon the rate of charge. During discharge a cell should never gas. If it does so, it is an indication that it has been run down much too low and needs immediate attention.

Of the above indications the first two, voltage and gravity, are those most commonly employed in operating. Gassing, while of great assistance as a guide or warning, cannot be depended upon for accurate results, and is only used when nothing but the most crude methods of operation are practical.

Either voltage or gravity readings alone could be used, but as both have advantages in certain cases, and disadvantages in others, it is advisable to use each for the purpose for which it is best fitted, the one serving as a check on the other.

Voltage has the great disadvantage in that it is dependent upon the rate of current flowing. Open circuit readings are of no value, as a cell reads almost the same discharged as it does charged. On the other hand, a voltmeter is a very easy instrument to read, and may be located wherever desirable

Specific gravity readings are almost independent of the current flowing, but the hydrometer is difficult to read, not very sensitive, and the readings must be taken directly at the cells.

Charge-In the case of the pasted type of plates, used almost entirely in vehicle service, experience has shown that the manner of charging has much to do with the life of the plates, and on this account it is sometimes stated that the life of a vehicle cell is proportional to the number of charges, rather than the number of discharges. On this account it is wise to charge the cells as moderately as practical. On the other hand, it has been found that if the plates are to be kept in good condition, it is necessary to occasionally charge them to a maximum, thus reducing all the sulphate. Also the different cells of a battery work as independent units, and while their efficiencies are approximately the

same, there is generally some slight variation, which if the cells are charged on a very efficient basis will sooner or later cause irregularity, the cells with the lowest efficiency dropping behind. It is necessary, therefore, occasionally to even them up or the low cells will get in trouble. To meet these conditions, charges are divided into two classes—regular charges which should be as efficient as possible, and overcharges given at stated intervals, which are carried to a maximum voltage and gravity, and intended to reduce all the sulphate in plates, and even up any irregularity in the cells.

Initial Charge—New batteries are usually received in a charged condition, but when this is not the case, the plates being shipped dry, or where the battery has been taken out of commission, it requires an initial charge before it is ready for service. This charge is not a complicated matter, but requires considerable time, frequently over 100 hours, and there is a very general tendency to cut it short. When the initial charge is not complete the plates will not be properly formed, a certain amount of sulphate will remain in them which will produce local action, and the capacity and life of the cells will be materially reduced.

In regular operation it is well to charge at the lowest possible rate. A large part of the wear on the plates is caused by the gassing, and the amount of gassing is reduced by a lower rate of current. Since the gassing occurs almost entirely near the end of the charge, it is especially important that the charging rate be low at this point, so that when the available time is limited the necessary number of ampere hours can be gotten into the battery with the least possible wear by having the current. rate high at the beginning of the charge and low at the end.

There is one point in connection with the charge which should be especially emphasized, namely, that the final voltage corresponding to a full charge is not a fixed figure, but varies widely, depending upon the charging rate, the temperature, the strength of the electrolyte, and age of the battery. For this reason, charging to a fixed voltage is unreliable and likely to result disastrously. The charge should be continued until the voltage or gravity cease rising, no matter what actual figures are reached. Old cells at high temperatures may not go above 2.4 volts per cell, whereas if very cold they have been known to run up to three volts.

The points to be especially emphasized in connection with the charge are:

First—On regular charges keep the rates as low as practical, and cut off the current promptly. It is preferable to cut off a little too soon rather than to run too long where there is any question.

Second—Overcharges must be given at stated intervals, and continued to a complete maximum. They should be cut off at the proper point, but when in doubt it is

safer to run too long rather than to cut off too soon.

Third—Do not limit the charge by fixed voltage.

Fourth—Keep the temperature within safe limits.

Discharge—The discharge largely takes care of itself, except that a battery should not be run down below its voltage limit. The rate of current has very little effect upon the life of the plates, provided the discharge is not carried down too far. Where a battery is completely discharged it should be charged as soon as possible, and if it has been run down too low the charge should be continued to a maximum similar to the overcharge.

Ampere Hour Meter-Many attempts have been made to develop apparatus which would automatically show the charge and discharge of a storage battery, but these have either been based on the wrong principles, or else the instruments would not stand the wear and tear to which they were subjected, and they have therefore not proved satisfactory. Within the last year or so, however, a mercury type ampere hour meter has been placed on the market, designed especially for battery use, and so far the results obtained have been very promising. This meter is equipped with a large dial and a pointer which can be set by hand to any point desired. This pointer revolves in one direction during charge, and in the opposite direction during discharge, and registers directly the ampere hour output or input to the battery. The mercury in which the armature disc is submerged acts as a dashpot, and seems to be very effective in damping the vibrations and jolts which such a meter has to stand.

During discharge the meter shows directly what capacity has been taken out, so that it is a simple matter to determine what is left in the battery. For charging the procedure is somewhat more complicated, although not seriously so. It is necessary to charge a battery for from 15 to 20 per cent, more ampere hours than are discharged in order to make up for the losses in the battery. The method used to accomplish this is to move the pointer ahead the proper number of ampere hours just before charging, then charge until the pointer comes back to zero. The meters are equipped with an electrical contact at the zero point, which can be made to automatically open the circuit if desired. As will be seen, this considerably simplifies the handling of the charge; but there is one point which must not be overlooked. and which should be strongly emphasized, namely, that the efficiency of a battery varies with the amount of work it does, being much lower for light work than heavy. In fact, as long as in commission, the battery needs regular charges, even if it does no work at all; in other words, its efficiency would then be zero. This condition can be handled in several ways. Under average conditions, it is probably safe to charge by the ampere hour meter for a

set period, say two weeks, provided at the end of this period the battery is given a regular overcharge. An alternative method is to give an additional charge once a week by the meter of whatever number of ampere hours is found needssary to keep the battery up. The regular bi-weekly overcharge will probably be found to be the safer method, especially in private service where the conditions are so variable, but whatever method is used, too much emphasis cannot be laid upon the fact that if a battery is to be kept in good condition, in addition to the ordinary charges with the ampere hour meter, regular overcharges must be given. The meter certainly gives promise of reducing the amount of attention a battery requires, but the danger is that it will therefore be assumed that it will eliminate all of it.

Short Circuits—Short circuits between the plates are largely eliminated through the use of the wood separator. This point therefore does not need any special attention beyond that of seeing that the separators are in good condition when installed. With the sediment under the plates, however, the case is different. It is a natural tendency to wish to run a battery as long as possible before putting it out of commission for overhauling. The result is that very generally the sediment is allowed to get up to the plates before the battery is washed. When the sediment reaches the plates there is a discharge of wasted current through it, which in turn necessitates that the cell be given more charge in order to hold it up, and the extra charging again throws down still more sediment. Further, the sediment becomes sulphated, and by local action with the active material of the plates in contact with it causes the active material to become sulphated, which again increases the tendency to washing out. The result is that the plates begin to lose their active material rapidly if the sediment is allowed to collect until it reaches them, and it is, therefore, evident that if a battery is to give its normal life it is absolutely essential that the sediment be cleaned out before, and not after, it reaches the plates. The rate at which the sediment collects depends largely upon the way a battery is handled, and it is, therefore, necessary to determine this rate for each individual case. A cell should be cut out after, say, fifty charges, the depth of sediment measured and the rate so obtained used to determine the time when the battery will need cleaning. As there is apt to be some variation in the amount of sediment in different cells, and as the 'sediment is thrown down more rapidly during the latter part of a period than at the beginning, it is always advisable to allow at least onefourth inch clearance. If the ribs in the bottom of the jars are 134 inches high, figure on cleaning when the sediment reaches a depth of 115 inches.

Before dismantling a battery for "washing," if practical, have it fully charged. Otherwise, if the plates are badly sulphated

they are likely to throw down considerable sediment on the charge after the cleaning is completed.

There have been a great many complaints of lack of capacity from batteries after washing. Almost without exception this is found to be due to lack of a complete charge following the cleaning. The plates are frequently in a sulphated condition when dismantled, and in any case are exposed to the air during the cleaning process, and thus lose more or less of their charge. When reassembled they consequently need a very complete charge, and in some cases the equivalent of the initial charge, and unless this charge is given the cells will not show capacity, and will soon give trouble again. This charge should be as complete as that described elsewhere in connection with the initial charge.

"Flushing" or replacing evaporation in cells with electrolyte instead of water is a most common mistake. The plates of a storage battery must always be kept covered with electrolyte, but the evaporation must be replaced with pure water only. There seems to be a more or less general tendency to confuse the electrolyte of a storage battery with that of a primary cell. The latter becomes weakened as the cell discharges, and eventually requires renewal. With the storage battery, however, this is not the case, at least to anything like the same degree, and unless acid is actually lost through slopping or a broken jar it should not be necessary to add anything but water to the cells between cleanings. Acid goes into the plates during discharge, but with proper charging it will all be driven out again so that there will be practically no ioss in the specific gravity readings, or at least one so slight that it does not require adjustment between cleanings. Thus, unless some of the electrolyte has actually been lost, if the specific gravity readings are low, it is an indication that something is wrong, but the trouble is not that the readings are low but that something is causing them to be low, and the proper thing to do is to remove the cause and not try to cover it up by doctoring the indicator. The acid is in the cells, and if it does not show in the readings it must be in the form of sulphate, and the proper thing to do is to remove the cause of the sulphation if there is one, and then with proper charging drive the acid out of the plates, and the specific gravity readings will then come back to the proper point. The too frequent practice in such cases is to add electrolyte to the cells in order to bring up the readings, which, as already explained, are only the indication of the trouble, and this further aggravates the condition, until finally the plates become so sulphated that lack of capacity causes a complaint. This practice of adding electrolyte to cells instead of water seems to be becoming more and more common. In general it is much the safer course to assume that the electrolyte is all right, and look for trouble elsewhere, than to attempt to doctor it by the addition of more acid, and a great deal of trouble today is the result of a misunderstanding of this one point.

The treatment required for bringing a low cell or battery back into shape, while quite simple, is one of the most misunderstood parts of battery operation. The causes of low cells may be very varied, but the results produced, and consequently the treatment required, are not so varied. The general procedure is as follows:

First-Restore the cell mechanically.

Second-Renew the electrolyte if there is any question as to its purity.

Third-Restore the cell electrically by charging.

Before dismantling a cell, if practical, have it fully charged, the mechanical restoration then simply covers the operation of examining the cell and putting it as nearly as possible back into its original condition. This should not be difficult for anyone who is familiar with the assembly of the elements.

Where there is any question as to its purity, the electrolyte should be renewed, as the expense is not great in the case of the small cells used in vehicle service, and it would hardly pay to have an analysis made. Where any considerable amount of electrolyte is under suspicion, the manufacturers will gladly analyze the same. It is well to always have the water used for replacing evaporation and new electrolyte, unless furnished by the battery manufacturers, tested

The most marked effect of an impurity is to cause the plates to become a bad color, the cells to become inefficient electrically, and in extreme cases the plates may be ruined.

When the electrolyte is renewed the jar and plates should be thoroughly washed, and the new electrolyte should be of about the same strength as that renewed in order to allow for any acid which may be in the plates.

The electrical restoration has been probably the greatest stumbling block, and largely through lack of understanding, as this operation consists in simply charging the cell until a maximum voltage and gravity is reached. The common mistake is to cut off the charge before it is complete, in which case the plates, being still sulphated, will not show capacity, and are likely through local action to soon get into bad condition again.

With the possible exception of trouble due to an impurity, it can be generally stated that chemically the final condition requiring treating is abnormal sulphating, and even where an impurity is present in the electrolyte its action is assisted by sulphating. It should be understood that sulphating is a normal as well as an abnormal process in the charge and discharge of storage batteries, and the difference is in the degree, not the process. The abnormal condition is that ordinarily referred to by the term. In normal service sulphating does

not reach the point where it is difficult to reduce, but if carried too far the condition becomes so complete that it is difficult to reduce, and injury results. A very crude method of illustrating the different degrees of sulphating is to consider it as beginning in individual particles uniformly distributed throughout the active material. Each particle of sulphate is then entirely surrounded by active material. The sulphate itself is a non-conductor, but being surrounded by active material the current can reach it from all sides, and it is easily reduced. This is normal sulphate. As the action goes further the particles of sulphate become larger and join together, and their outside conducting surface is greatly reduced in comparison with their volume, so that it becomes increasingly difficult to reduce them, and we have abnormal sulphate.

The general cure for sulphating is charging, so that a cell having been mechanically restored the electrical restoration consists simply in the proper charging. Sulphate reduces slowly, and on this account it is a good plan to use a rather low current rate. High rates cause excessive gassing, heating, and do not hasten the process appreciably, so that it is the safer as well as the more efficient plan to go slowly. A good rate is about one-fifth normal. The length of charge will depend upon the degree of sulphating. In one actual case it required three months' charging night and day to complete the operation, but this was, of course, an exceptional one. The aim should be to continue until careful voltage and gravity readings show no further increase for at least ten hours and an absolute maximum has been reached. In serious cases it may be advisable to even exceed this time in order to make absolutely sure that all sulphate is reduced, and where there is any question it is much safer to charge too long rather than to risk cutting off too soon. A partial charge is only a temporary expedient, the cell still being sulphated will drop behind again.

Since the specific gravity readings are affected not only by the charge but also by the evaporation and changes in temperature, it is advisable, where an absolute maximum is to be reached, to eliminate these. The evaporation should be replaced with sufficient frequency to keep the electrolyte accurately at a fixed height above the plates. In this way water is added so frequently that very little has to be added at any one time, and the effect on the specific gravity readings is negligible. The temperature variations are eliminated by reading the temperature of the electrolyte, when specific gravity readings are taken, and correcting the latter to some standard temperature, such as 70° Fahr. This correction is made by adding one point (.oo1 specific gravity) for every 3 degrees above 70° Fahr., and subtracting one point for every 3 degrees below 70° Fahr.

When the charge is complete the specific gravity of the electrolyte should be adjusted to the proper point, and the cell is ready for service. Where there is time, and the facilities are at hand, it is a good plan to take a test discharge in order to make sure that everything is all right.

Failure in the restoration of low cells is probably more often due to cutting off the charge too soon than to any other cause, and from the troubles which are being reported this point evidently needs to be brought out more strongly.

In closing, a word or two about the vehicles themselves As manufacturers we wish to admit without argument that the battery is the most important part of the vehicle, but, on the other hand, we would like to protest against the frequent practice of blaming the battery for everything that goes wrong. The battery is rated in ampere hours, not mileage, and when the mileage of a vehicle falls short trouble should be looked for in the vehicle as well as in the battery. Batteries are regularly rated at their four hour discharge rate, this being about an average running rate for vehicles. The capacity, however, varies widely with different discharge rates, decreasing as the rates increase, so that anything which causes the vehicle to consume more current will more than proportionately reduce its mileage. For example, suppose that due to inefficient tires, poor bearings or binding brake, a normal current of 20 amperes is increased to 30 amperes. If the ampere hour capacity were still same, and there were no other losses, the mileage would be reduced about one-third. This increase in current, however, reduces the actual capacity of the battery by about 10 per cent. The average discharge voltage is also reduced, and the drop in wiring of the vehicle is increased, so that the watts delivered to the motor are still further reduced, and finally the motor itself is somewhat less efficient at the higher rate, so that the net result is that the mileage of the vehicle, instead of being reduced by one-third, is actually cut down by about one-half. It is thus evident how important it is that the vehicle, as well as the battery. be kept in the best of condition.

As has already been stated, no attempt has been made to cover many of the details of battery operation, but rather to emphasize and explain some of the most common errors found in the handling of the vehicle batteries of today, and of these probably that which should be brought out most forcibly is the matter of flushing cells with electrolyte instead of water. Keep the plates covered with electrolyte, but use only pure water, not acid, for replacing the evaporation.

#### Premier Agents' Convention.

During the week beginning September 20 the Premier Motor Manufacturing Company will entertain its agents and representatives at the factory in Indianapolis. On Tuesday evening there will be a banquet at one of the hotels, followed by a run to French Lick Springs, and return on Wednesday and Thursday.

#### National Good Roads Convention.

The second annual national good roads convention was opened in Cleveland, Ohio, yesterday, September 21, and will remain in session three days. Most of the prominent organizations interested in good roads are represented at the convention, and the governors of many of the States in the Union have sent delegates. The United States Government is represented by Logan Waller Page, director of the United States Office of Public Roads, and members of his staff. In addition to the large number of addresses by highway engineers, etc., practical demonstrations are being given upon different roads in and around Cleveland. Another feature of interest is a large exhibit of road making machinery in the Central Armory of Cleveland. This is said to be the first time that such an exhibit has ever been arranged. The organizations officially represented at the convention are as follows: American Automobile Association, National Grange, United States Office of Public Roads, American Road Makers' Association, National Association of Automobile Manufacturers, Association of Licensed Automobile Manufacturers. and the American Motor Car Manufacturers' Association.

The Cleveland A. C., whose members have arranged the program for the practical demonstrations and social features and entertainments, are the official headquarters for the delegates and guests.

The convention proper is being held in the Chamber of Commerce Hall, where President Lewis R. Speare, of the American Automobile Association, delivered the opening address at 10 o'clock on Tuesday morning. Governor Harmon, of Ohio, then extended the welcome of his State to the delegates, and Mayor Johnson, of Cleveland, followed in welcoming the good roads enthusiasts to the city. Chairman George C. Diehl, of the national committee, acted as presiding officer, and introduced the speakers. Following is the program of the convention, which will be fully reported in our next issue:

TUESDAY, SEPTEMBER 21. CHAMBER OF COMMERCE HALL. MORNING SESSION.

10 a. m.—Opening address, President Lewis R. Speare, of the American Automobile Association. "Welcome to Ohio," Hon. Judson Harmon, Governor of State of Ohio.

10:25 a. m.—"Address of Welcome," Hon. Tom L. Johnson, Mayor of Cleveland,

10:40 a. m.—"The Second Annual National Good Roads Convention," and introduction of speakers. George C. Diehl, presiding officer and chairman of the national committee, directing the convention.

10:50 a. m.—"Good Roads of the State of Ohio,"
James C. Wonders, State Highway Commissioner
of Ohio

11:15 a. m.—"State Aid," Hon. James H. Mac-Donald, State Highway Commissioner of Connecticut.

AFTERNOON SESSION.

2 p. m.—"The National Grange and Good Roads," Ex-Gov. N. J. Bachelder, master of the National Grange.

2:30 p. m.—"The New England Plan for Connecting Lines of Trunk Highways," George S. Ladd, special good roads lecturer of National Grange.

3 p. m.—"The Farmers' Interest in Road Improvement," Hon. T. C. Laylin, master Ohio State Grange.

3:30 p. m.—"The New York State Grange and Good Roads Legislation in That State," Hon. F. N. Godfrey, master New York State Grange.

4 p. m.—"Good Roads in the State of Pennsylvania," E. J. Kent, vice president Automobile Club, Pittsburg, Pa.

4:30 p. m.—"Road Maps and Signs," Powell Evans, president Automobile Club of Philadelphia.

WEDNESDAY, SEPTEMBER 22.
CHAMBER OF COMMERCE HALL.
MORNING SESSION.

Convention called to order by Presiding Officer George C. Diehl, national chairman, at 10 a. m.

10:15 a. m.—"Road Situation in the United States as Compared with Foreign Countries," Logan Waller Page, director of Office of Public Roads, Washington, D. C.

10:45 a. m.—"New York State Trunk Lines," Hon. S. Percy Hooker," chairman New York State Highway Commission.

11 a. m.—"Illinois Good Roads," H. H. Gross, president Illinois Farmers' Good Roads League.

11:25 a. m.—"Treatment of Earth Roads," D. Ward King, Missouri State Board of Agriculture. 11:45 a. m.—"Postal Progress League," James L. Cowles, secretary and treasurer.

AFTERNOON SESSION.

12 noon.—Practical demonstrations and road inspections.

2:30 p. m.—Complimentary luncheon will be served at the Randall Track Clubhouse.

THURSDAY, SEPTEMBER 23.
CHAMBER OF COMMERCE HALL.
MORNING SESSION

The convention called to order by Presiding Officer George C. Diehl, national chairman.

10:15 a. m.—"Macadam Roads," A. B. Fletcher, secretary Massachusetts Highway Commission.
10:45 a. m.—"Bituminous Road Materials," Pre-

10:45 a. m.—"Bituminous Road Materials," Prevost Hubbard, chemist United States Office of Public Roads.

11:15 a. m.—General discussion.

AFTERNOON SESSION.

12 noon.—Boat ride on Lake Erie. Passenger steamer City of Detroit will leave foot of Superier street. Complimentary luncheon will be served on board.

8:30 p. m.—Theatrical performance at Chamber of Commerce Hall by the Hermit Club, of Cleveland. Music by Hermit Club Orchestra.

#### Speedway to Be Brick Paved.

A brick surface is to be placed on the course of the Indianapolis Motor Speedway at Indianapolis, this decision having been reached after a demonstration with a number of different materials. The paving work is now in progress, and will require about 3,500,000 brick. At the recent races on the course it was demonstrated that the crushed stone and oil surface would not be satisfactory for the purpose. The brick course will be the only one of its kind in the world. The company is also building an aerodome on the grounds for the aviation meet in October. It will be 300 feet long and 60 feet wide.

It is reported that the Japanese Government has purchased a motor truck for the Imperial Arsenal in Tokio from the firm of Laurin & Klement, Jungbunzlau, Bohemia. The truck is equipped with a four cylinder 18-22 horse power motor, and designed for useful load of 1½ tons. It is to be used for transporting military equipment between the arsenal in Tokio and machine shops which are located at considerable distance.

#### Maintenance and Repairs

#### Roadside and Emergency Repairs. By H. H. Brown.

Perhaps one of the best of the old proverbs for the motorist (especially he who drives his own car) to keep in mind is that "an ounce of prevention is worth a pound of cure," or to translate this into the language of the motorist, "an ounce of oil is worth a pound of new babbitt metal." It is probably a fact that the majority of road-side breakdowns, barring tire trouble, might be avoided by careful inspection of the car from time to time.

However, accidents will happen in the best regulated machines (as well as families), and in many cases are unavoidable. For instance, a stone or other obstruction may cause a leak in a low hung gasoline tank. A ball may crack in a bearing and untold havoc may result from this cause.

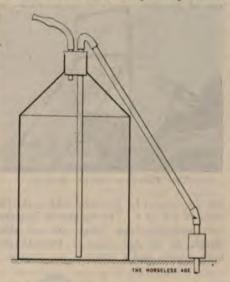

In a more or less permanent repair, made in a shop or garage, one is able to take a reasonable time to study how to do the job. Then, the tools and materials being at hand, it is in most cases a comparatively easy matter to proceed. However, in the emergency repair the circumstances are quite different, In the first place, tools, materials and skilled help are generally conspicuous by their absence. Then, again, little time may be given in which to figure out a method of getting over the difficulty. The following occurrence illustrates this latter point: Some time since a breakdown occurred on a road on which there was a trolley line that led to the nearest town, a distance of about 5 miles. The nature and extent of the trouble had been barely ascertained when the trolley car came in sight. It had been previously ascertained that the cars ran but once an hour, and it was then after 5 o'clock. As the town was a small one, if this first car was missed the chances for an all night stop of the machine at this point would have been exceedingly good. Fortunately in this case familiarity with the general features of the parts involved and their general dimensions allowed of working out a plan of action on the trolley while on the way to town which would allow for possible errors in estimation of dimensions, so that all was done within an hour and a return made on the next car to the machine, which was then able to proceed on its way in less than ten minutes.

To partially offset these disadvantages sightliness, durability and the comfort of passengers do not have to be considered to the extent that is only natural in the case of a more permanent repair.

The following incident may illustrate this assertion: Some time ago a chassis was delivered by an agent to a body builder in a town about 50 miles from the home city of the agent. When one of the salesmen attached to the agency went for the car it

was discovered that the copper tubing fitted with the proper unions for connecting the carburetor and gasoline tank was not in evidence. To have waited till it could have been obtained would have meant a day's delay, to say nothing of the time and carfares of the salesman. In this case, however, a 5 gallon kerosene can, with a stopcock at the bottom, as well as 10 or 12 feet of rubber tubing, was available. One end of the tubing was slipped over the stopcock on the can and made tight with twine. The can was then placed on the footboard to the left of the driver and the tubing led under the bonnet, and connected in a similar manner to the carburetor. This makeshift device only took about ten minutes to rig, and enabled the car to be driven a distance of between 50 and 60 miles, with only one filling of the extemporized tank on the road, and that at less than 15 miles from home.

It is seldom that two precisely similar

accidents happen to a motorist nowadays, and it is still more seldom that the same means of effecting a temporary repair are available. It is well, however, to figure out how else such a repair might be effected with the means at hand.

This is a good practice for a variety of reasons. While the method used may have been the best at the time with the means at hand, yet in another case the same means may not be available, or, owing to differences of the break, other means may have to be resorted to. Then, again, while there is, of course, nothing like practice, yet if one accustoms himself to figuring the way out of imaginary emergencies, when the real one comes he is much more likely to get out of it easily than if he had not given any thought to the matter.

Let us take the case in which the tank and carburetor connection was missing. It will probably have occurred to some that the rubber tubing might have been used to make connections direct between the regular tank and the carburetor. This, of course, might have been done, and probably would in case the 5 gallon can had not been available. However, there were quite a few practical reasons against this course.

In the first place, there was no stopcock at the tank. Secondly, a joint made between the nipple at the tank and the rubber hose could hardly be considered reliable under the circumstances, to say the least. It will readily be seen that quite a good sized leak might occur which would not affect the operation of the machine, but would perhaps leave it stranded at some very inconvenient point.

On the other hand, in using the can, the joint at the can was constantly under two pairs of eyes, those of the driver and the front passenger, and as the top of the can was off any undue loss of gasoline would soon have been noticed, and the defect sought and remedied.

To show what may be done in case of an accident, let us suppose that the gasoline tank has a leak in it which renders it for the time being useless, and that the gasoline pipe is broken off. On going to the nearest grocery store we find that the owner sells gasoline in ordinary cans, which are closed by a good cork stopper, of which he has plenty. Other than that, nothing is available, except what is on the machine.

On examination we find that a considerable length of the tubing leading from the carburetor is in good order. This is led up till it projects above the floor boards. Further examination shows us that we have quite a few feet of copper tubing which runs from our generator to our headlights. Also four pieces of rubber connecting tubing used to connect the lamps and the generator to the copper tubing.

In the first place a cork is used to form a reducing coupling between the gasoline piping and the smaller copper piping formerly used for the acetylene gas lead. A length of the copper acetylene lead is passed through the cork of the gasoline can until it almost touches the bottom. A smaller length is then just passed through the cork and a length of about a foot of rubber tubing placed on it. By a length of the copper and two small lengths of the rubber the can is now connected to the carburetor pipe. The can in this instance is placed to the left of the driver. By blowing into the short tubing on the can the gasoline will flow to the carburetor and will continue to do so, owing to the siphon action.

## Cranked Motor With Gears in Mesh.

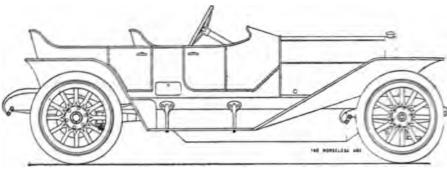

G. G. Swackhamer, of White Plains, N. Y., recently caused an accident by cranking his car with the change gear in the first speed position. Mr. Swackhamer's car was brought to a stop in the road owing to a block caused by an ice wagon. He jumped out to crank the engine, but forgot to first move the change gear lever to the neutral position, and the result was that as soon as the engine began to fire the car jumped forward, knocking him down, knocking down two people walking on the sidewalk and smashing a window.

## NEW VEHICLES AND PARTS >>

#### The G J G Car.

The G J G Motor Car Company, which has recently begun the manufacture of automobiles in White Plains, N. Y., has brought out a runabout model known as the Pirate, and a touring car model known as the Scout, both of 40 horse power, and listed at \$2,250 and \$2,500 respectively. The motor is a four cylinder vertical one with cylinders cast in pairs, of 43/4 inch bore and 5 inch stroke. The water jacket heads are separate, and the water is circulated through the cooling system by a centrifugal pump. A Bosch high tension magneto furnishes the ignition current. The change gear is of the selective type, with three forward speeds and one reverse. The shafts and gears are made of imported chrome nickel steel, and the shafts run in Rhineland imported annular ball bearings. The clutch is of the conical type, faced with leather, with springs under the leather to insure gradual engagement. The rear axle is of the full floating type, and the driving gears and shafts are of heat treated Krefeld imported chrome nickel steel. The front axle is a single piece drop forging of Krefeld chrome nickel steel, with Elliott type steering heads. The frame is made of heat treated pressed steel, and has four cross members. The motor and change gear are carried on a sub-frame. The frame is supported in front by semi-elliptic springs of alloy steel, 40x2 inches, and in the rear by three-quarter elliptic springs,

THE SCOUT CRUISER TOURING CAR.

56x2½ inches. The steering gear is of the worm and sector type, and is adjustable for wear. Both cars have a wheel base of 121 inches, a standard tread, and 34x4 inch wheels, with quick detachable rims. The gear ratio is 2½ to 1 for the runabout, and 3 to 1 for the touring car,

THE FRICTION WIND SHIELD.

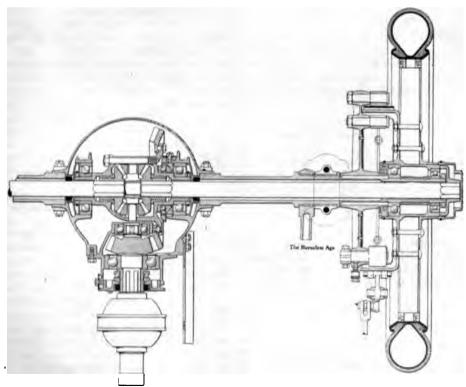

but the car can be furnished with a special ratio of 3½ to 1. The equipment includes two acetylene head lights, two oil side lamps, an oil tail lamp, a Prest-O-Lite tank, a horn, and a complete set of tools.

The automobile department of the American Locomotive Company, Providence, R. L. will next year turn out three chassis models, viz., a six cylinder, 60 horse power; a four cylinder, 40 horse power, and a four cylinder, 22 horse power. The most important change over last year's construction is that all of the new models will have shaft drive, while formerly the 40 and 60 horse power models were chain driven. The rear axle construction used on the two larger chasses is the same as that formerly used for the small town car. The axle is of the floating type, the supporting member consisting of a one piece drop forging, with a large ring in the middle and tubular arms stiffened by ribs above and below. Another change relates to the ignition system. The Bosch dual high tension system will be used. comprising both a magneto and batteries, operating on one set of spark plugs. A new line of aluminum bodies has been designed for 1910, the seat panels consisting of sheet aluminum and the door frames of aluminum castings. The moldings about the panels are rolled in with the aluminum sheet, instead of being attached separately. The prices of the different models have been reduced and are now as follows: Twenty-two horse power town car, limousine or landaulet, \$4,350; 40 horse power touring car, \$4.750; 40 horse power limousine or landaulet, \$5.500; 60 horse power touring car, \$6,-000; 60 horse power limousine or landaulet, \$6.750. The cars are furnished with a very complete equipment, including a top, side lamps, horn, tire brackets, etc.

#### The Friction Wind Shield.

A novel type of adjustable wind shield has been placed on the market by the Newark Rivet Works, 262 Lafavette street, Newark, N. J. As will be seen from the illustration, the shield is divided, as usual, a little above the centre, and is held in any position desired by friction. It is claimed that the shield absolutely stays where placed, but can be adjusted to any position from the driver's seat. The frame is made of seamless brass tubing, with a sub-channel to hold the glass firmly and prevent rattling. The top half can be swung forward to a position substantially parallel with the stay rods, when it will divert the air currents over the heads of the occupants of the car, thereby considerably reducing the air resistance.

SECTIONAL VIEW OF ALCO FLOATING REAR AXLE.

aimed. The lower half of the shield e arranged either vertically, as shown, lengthening the stay rods, inclined ardly so as to come as near to the g wheel as permissible, and this adent, in connection with the various adents of the top half, gives a great variof possible combinations.

The Auto Lighter.

Motor Specialties Company, of 222 street, Boston, Mass., have brought system for lighting acetylene autolamps from the driver's seat. The tus comprises essentially three parts, controller, an induction coil and a . The controller is a combined gas and electric contact device, and is se-

BURNER.

to the dash of the vehicle. By a turn of the handle to the left the om the generator or tank is admitted burner, and by the same operation a of sparks is produced which ignites mp. A motion of the handle in the te direction turns the gas off and exshes the lamps. The controller is atically locked when in either the or "off" position. The coil is the

CONTROLLER.

single unit vibrator coil, finished in any and brass. It measures 3x3½x5. With each outfit are furnished two is, which are tapped to fit the stand-urner thread, and can be instantly it to any headlight. A bracket clamped burner carries the two electrodes in the ends of which the igniting play. The spark gap is in close nity to one of the gas jets. Among ivantages claimed for the apparatus at it enables the driver to ignite and

extinguish the headlights from the seat without stopping the car, and obviates the annoyance of matches, especially in a strong breeze. The apparatus can be connected with any source of current.

#### The Metzger Motor Car Company— Organization and Product.

Articles of incorporation were filed in Lansing, Mich., on September 20 by the Metzger Motor Car Company, of Detroit, a new corporation to manufacture automobiles. The capital stock is \$500,000, of which \$300,000 is paid in. The stockholders and officers of the company are Byron F. Everitt, president; William Kelly, vice president, and William E. Metzger, secretary and treasurer. The new company will manufacture a car designed by William Kelly, who designed the Wayne and E-M-F cars. Mr. Kelly is one of the pioneers of the industry, having designed and built automobiles as early as 1899. Messrs. Everitt and Metzger are well known to the automobile trade and public, having been officials of the Everitt-Metzger-Flanders Company up to the time they sold their interests in this company to the Studebaker Manufacturing Company, on May 1 last. B. F. Everitt becomes president of the new company, which same position he held with the E-M-F Company. William E. Metzger, the secretary and treasurer of the new company, before his connection with the E-M-F Company was sales manager of the Cadillac Automobile Company, and had a retail store in

The new company will manufacture a runabout and a five passenger car, to be sold at popular prices. The models of the new car have been running in the streets of Detroit for some time, and a photograph of one of them is shown herewith. About thirty days ago the new company purchased the plant of the Jacob Meier Company, trunk manufacturers, located at Milwaukee avenue and the Grand Trunk Railroad, Detroit. This plant was built several years ago, and is said to be well located for the automobile business. It occupies 21/2 acres of ground. The plant is located between the East boulevard and the Detroit White Lead Works at the viaduct. Additional buildings have already been decided upon. The machinery is being installed, and

the company plans to begin deliveries within ninety days.

Gramm-Logan Company Increases Capital.

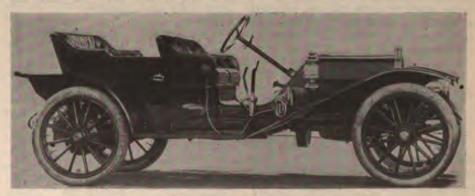

The Gramm-Logan Motor Car Company, Bowling Green, Ohio, held its annual stockholders' meeting at the conclusion of its first fiscal year on September 14. It was decided to increase the capitalization from \$100,000 to \$300,000, and to increase the size and equipment of the plant. The intention is to treble the output of the company for the coming year. The following officers were elected: A. L. White, president of the Lima Locomotive and Machine Works, of Lima, Ohio, president; B. A. Gramm, vice-president and general manager; F. E. Lamb, secretary, and J. B. Wilson, president of the Grand Rapids Banking Company, treasurer.

The New Buildings of the National Motor Vehicle Company.

The National Motor Vehicle Company, of Indianapolis, Ind., have begun the erection of a large addition to their Twentysecond street factory. The new building is of keystone shape, being 154 feet at one end and 99 feet at the other, and 210 feet long. It is of concrete construction to the window sill line and metal lath covered with cement and steel, and wood beam construction from there to the plate line. It has a gable roof. This building, part of which will be two stories, will be occupied by the blacksmith shop and assembling room downstairs, and by the trimming shop upstairs. Much new machinery is being installed.

General Motors Capital Now \$60,000,000.

The General Motors Company has filed with the Secretary of State of New Jersey an amended certificate increase in its capital stock from \$12,500,000 to \$60,000,000. Of this amount \$40,000,000 is common stock, and \$20,000,000 preferred stock bearing 7 per cent. cumulative dividends. The General Motors Company controls the Buick Motor Company, the Olds Motor Works, the Cadillac Motor Car Company, the Rainier Motor Car Company, the Reliance Motor Truck Company, the Oakland Motor Car Company and a number of parts concerns.

## Why Bushings Turn on Shafts and Not in the Machine Parts.

Editor Horseless Age:

Although this system has been almost universally adopted by automobile designers, I am at a loss to see the advantage of attaching a bronze bushing to the pinion in place of pressing it on the shaft, as apparently there is the advantage of a larger wearing surface by the use of the later method. On a certain popular car there is used a triple gear drilled to receive a 11% inch bushing. The thickness of the bushing amounts to three-sixteenth inch, reducing the inside diameter to three-quarter inch, while by making the bushing fast to the shaft the bearing surface could be increased to 118 inch by the length of the bushing. It seems to me this would add to the compactness as well as the durability of some planetary transmissions. The same rule, of course, would apply to most of the present uses of bronze bushings. WALTER VETTER.

[There are two reasons why your idea is not likely to be adopted by machine designers. In the first place the friction and wear are proportional to the diameter of the friction surface or bearing surface. If you increase the diameter from three-quarter inch to 11/8 inch, leaving the total pressure on the bearing and the speed of revolution the same, the power loss due to friction would be increased substantially in the ratio of three-quarters to 11/8, which would be a disadvantage. The pressure per unit of surface on the bearing area would, of course. be less, but as the speed would be greater in the same proportion the bearing would wear at least just as rapidly as the smaller one, unless the regular bearing was altogether too small for the load it has to carry.

The other reason is that, where a bronze bushing is used the wear is not confined to the bushing, and quite often the shafts which run in these bushings are cut and worn to such an extent that they must be renewed. While it is often a very simple matter to renew one of these shafts (this is so in the case you cite, where the shaft probably consists of a short length of cold rolled steel), it would be quite expensive to replace the entire gear if its bore were worn, due to lack of lubrication or for some other reason.—Ep.]

#### Heating a Private Garage.

Editor Horseless Age:

Will you kindly tell me direct or through your columns what you think is the best way to heat a private garage? F. A. F.

[If the garage is not near enough to your home to make it practicable to run pipes from the steam or hot water heating system of the house to the garage, the best plan is to install a small heater of some kind in a separate room outside the garage, and conduct the hot water, steam or hot air through pipes in the garage. The one point to be looked out for is that there must be no communication between the garage and the room in which the heater is located, as in case gasoline should be spilled in the garage the vapor might get into the heater room and be ignited.

If any of our readers have solved the problem of heating a small detached garage in a simple and effective way, we should be glad for a description of their installation.—Et.]

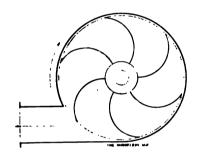

#### Centrifugal Pumps.

Editor Horseless Age:

I read with interest the article on centrifugal pumps in your September 8 number, and would like to ask your opinion of the design enclosed.

J. J. JENNINGS.

[The blades are too much inclined to the radia!s at their outer ends, and only the blades at any particular moment opposite the delivery pipe have any useful effect, as the rotor seems to fit closely in the casing

all around, leaving no space for the water to flow. The pump would work, of course, but would be rather inefficient.—ED.]

#### Queries.

Editor Horseless Age:

As a subscriber to your valued paper, I should like to ask the following questions through your columns:

What are the six principa! parts that should be examined in purchasing a motor car that has been run two or three years, what would be the best way to examine and test these parts, and what would be a good test to give the whole car in general?

Is it possible to muffle the exhaust gas of a four cylinder motor too much, and cause undue back pressure?

What are the advantages and disadvantages of the three cylinder, two cycle air cooled motor? Would such a motor, combined with a friction drive transmission and aluminum body, make a good light serviceable, five passenger car of 18 horse power and about 1,200 pound; weight?

"STUDENT."

[Probably the six most important parts to examine on a second hand car are the motor, the change gear, the steering gear, the tires, the brakes and the body. The best plan undoubtedly is to ask for a 50 or 60 mile demonstration, including some

steep hills. The motor is really the most important part of all, and in second hand cars it frequently shows a lack of power. The hill test will bring out whether it still develops sufficient power or not. The steering gear can be tested by turning the wheel first one way and then the other, and observing how much back lash it has, that is, how far it can be moved without moving the road wheels. The tires can be easily examined by the eye as to the condition of their threads. If these are much worn and cut, the probability is that a new set will have to be secured at an early date. Probably the best test of the change gear is to open the gear box and examine the teeth. If these are still of normal thickness, the gear is probably in good condition, whereas if the teeth have been worn thin the gear will not last long. To test the brakes, see whether they will hold firmly when set, and if there is still a possibility of further adjustment. The linkages can easily be examined for "shake." Another part that should be given an examination is the body, but this, of course, is a very obvious mat-

If the muffler of a four cylinder motor does not present a sufficiently large passage for the exhaust gases, either because the exhaust openings were made too small in the first place, or because they are choked by carbon and oil, the muffler will cause back pressure on the engine.

A three cylinder two cycle air cooled motor, if well made and so designed that it cools properly, should be a very good motor for a light car. Very much, of course, depends upon the design and the workmanship. A friction drive should be quite suitable for such a motor. We doubt, however, whether you will succeed in keeping the weight of a five passenger vehicle down to 1,200 pounds. We do not know of any regularly manufactured five passenger cars weighing as little as this, and vehicles built in an experimental shop are usually heavier than those regularly manufactured.—ED.]

## Starting Six Cylinder Engines on Compressed Air.

Editor Horseless Age:

I want to thank you for your reply in your issue of 8th inst, to my inquiry about starting six cylinder motors on compressed air, without the use of extra cams, valves, etc. In regard to the objectionable check valve I should explain that I have made a special form of check that works directly oppositely from the usual one, in that it is always wide open except when air pressure strikes it, when it closes, opening again immediately when the air pressure in the pipe is released or cut off.

JOHN W. SLATER.

#### Motor Horse Power.

Editor Horseless Age:

Will you kindly state in your paper the relative power, hill climbing ability, etc., of

a motor 41/2 bore by 41/2 stroke, and one 4 bore by 5 stroke, other things being equal? EDWARD HILL BALDWIN.

[According to the A. L. A. M. formula, which is almost exclusively used in this country, the first of the two motors should deliver 26.5 per cent, more power than the second. According to the German Automobile Technical Association's formula, which takes account of the stroke, the first motor should give 18 per cent, more power than the last. If the compression pressures are fairly nearly alike, the valves of proportionate size, and the workmanship is nearly the same on both motors, the motor of 41/2 inches bore is sure to give the most power.

#### Imports and Exports for July.

During the month of July last there were imported into this country 144 automobiles valued at \$300,025 and parts valued at \$86,-432, as compared with 115 automobiles valued at \$224,578 and parts valued at \$47,369 in July, 1908. Of the 144 cars imported last July, 60 were from France, 55 from Italy, 16 from Germany, 8 from the United Kingdom and 5 from other countries. During the seven months ending with July, 1909, there were imported 864 automobiles valued at \$1,592,643 and parts valued at \$460,998, as compared with 558 automobiles valued at \$1,170,624 and parts valued at \$298,755 during the same period in 1908, and 559 automobiles valued at \$1,827,590 and parts valued at \$466,637 during the same period in

During July last there were exported 470 American automobiles, valued at \$874,685 and parts valued at \$87,558, a total of \$962,-243, as compared with 238 cars valued at \$588,560 and parts valued at \$55,341, a total of \$643,901 during the same month last year. During the seven months ending with July, 1909, there were exported 1,780 cars valued at \$4,550,019 and parts valued at \$425,870, as compared with 1,528 cars valued at \$3,-223,166 and parts valued at \$390,775, a total of \$3,613,941, during the same period last

During the seven months ending with July, 1909, there were exported from this country 65 automobiles of foreign manufacture valued at \$290,881 and parts valued at \$1,000, as compared with 52 automobiles valued at \$265,711 and parts valued at \$2,702 during the same period last year.

We have received a copy of a "List of Permits for Operating Motor Vehicles in Ontario." It appears that this list is sent to the clerks of all the different cities in the province. We believe that the practice of issuing such lists in printed form is limited to the Canadian provinces. The large number of addresses in the United States contained in the list shows that many Ameriean motorists tour in Canada. Of course most of the Americans holding such permits reside in the boundary cities, Detroit and Buffalo, but there are also many addresses farther inland given.

#### The Frank A. Munsey Tour.

The Reliability Tour from Washington, D. C., to Boston, Mass., and back, organized by newspaper publisher Frank A. Munsey, drew thirty-seven entries as follows:

1-Chalmers-Detroit, Chalmers-Detroit Machine Company, Detroit. 2—Hudson, Hudson Motor Car Company, De-

troit, Mich.

Mitchell, W. M. Cram, Philadelphia, Pa 4-Premier, the Motor Car Company, Philadelphia, Pa.

-Washington, Carter Motor Car Corporation,

Washington, D. C. 6—Stevens-Duryea, F. W. Eveland, Philadelphia. 7—Ford, Charles E. Miller & Brother, Washington, D. C.

8-Jackson, Jackson Automobile Company, New York.

9-Maxwell, Lambert Automobile Company, Balti-

10-Oldsmobile, Olds Motor Works Branch, Balti-

11-Maryland, Sinclair-Scott Company, Baltimore. 12-Pullman, York Motor Car Company, York, Pa. 13-Pullman, York Motor Car Company, York, Pa.

14-Spoerer, Carl Spoerer's Sons Company, Balti-

15-Columbia, Frank P. Hall, Washington, D. C. 16-Croxton-Keeton, Croxton-Keeton Motor Car Company, Massillon, Ohio.

17-Croxton-Keeton, Croxton-Keeton Motor Car Company, Massillon, Ohio,

18-Corbin, Corbin Motor Vehicle Company, New Britain, Conn.

-Hupmobile, Joseph Wiesenfeld, Baltimore. 20-Winton, George F. Whiting, Baltimore. 21-American Simplex, Simplex Motor Car Com-

pany, Mishawaka, Ind. 22-Cameron, Cameron Car Company, Beverly,

Mass. 23-Atlas, Atlas Motor Car Company, Springfield,

Mass. 24-Crawford, C. E. Eckenrode, Baltimore.

25-Acme, N. S. H. Sanders, Boston, Mass.

26-Reno, John J. Loughran, Philadelphia, Pa.

27-Matheson, Matheson Automobile Company, New York.

28-Renault, L. H. Shaab, Baltimore, Md.

29-Hupmobile, Hupp Motor Car Company, Detroit, Mich.

30-Marmon, Nordyke & Marmon, Indianapolis, Ind.

31-Washington, Carter Motor Car Corporation, Washington.

32-Washington, Carter Motor Car Corporation, Washington. 33-Franklin, Franklin Automobile Company, New

34-Selden, T. S. Patterson, Rosemont, Pa.

35-Michigan, Michigan Motor Car Manufacturing Company, Detroit, Mich.

36-Elmore, Frank Hardart, Philadelphia, Pa. 37-Pullman, H. Clay Waldman, Jr., Baltimore.

The tour started from Washington yesterday, September 21. The contestants will compete for one grand prize trophy and six other trophies, all of which have been specially designed for the occasion.

The grand trophy has for a base a board slab of Flemish oak, upon which a design of silver is worked out. Engraving and etching are employed to reproduce a touring scene in which a large touring car is shown just making a turn in a country road. On the upper right hand section of the slab the dark sky is lighted by cloud effects in silver, while the upper left part of the space is devoted to the lettering. The relief work of the silver against the dark oak background makes a most attractive contrast. The whole scene is surrounded by a broad band of etched silver.

Plates also form the design for the awards in the six divisions. The plates are oval in shape and 22 inches high, measured through their greatest diameter. The base is mahogany mounted with silver. Near the top of the silver plate is an automobile with the Capitol as a background. Just below this is the inscription, which reads, "Frank A. Munsey Reliability Contest. First prize (name of division), Washington, D. C., to Boston, Mass., and return."

The technical committee, which has complete charge of the run after the start, is composed of Frank H. Trego, of the Chicago Motor Club, chairman; Dr. J. R. Overpeck, of the Quaker City Motor Club, and Jesse L. Cassard, Jr., of Baltimore, Md. Mr. Munsey is the publisher of the Washington Times, the Boston Journal, the Baltimore News and the Philadelphia Evening Times, and the contest touches all of the different cities in which his newspapers are published. Following is the complete itinerary:

	Miles.
September 21-Washington, D. C., to Bal-	
timore, to Philadelphia, Pa	195-3
(Via York and Lancaster.)	
September 22-Philadelphia, Pa., to Mil-	
ford, Pa	132.6
(Via Allentown and Delaware Water	
Gap.)	
September 23-Milford, Pa., to Albany,	1354
N. Y	158.5
(Via Goshen and Kingston.)	
September 24-Albany, N. Y., to Boston,	
Mass.	194.2
(Via Springfield and Worcester.)	
September 25—In Boston.	
September 27—Boston, Mass., to New	
York City	239.4
(Via Providence, Wilimantic, Hartford,	239.4
New Haven, Bridgeport.)	
September 28-New York City to Phila-	
delphia, Pa	194.3
(Via Perth Amboy Ferry, Atlantic City,	. 34.3
Camden.)	
September 29-Philadelphia, Pa., to Balti-	
more, to Washington, D. C	163.9
(Via Wilmington and Newark.)	
Total mileage	1,282.2
Number of running days-7.	
Average per day-182 miles	

#### Plantation Rubber Production of the Federated Malay States.

Vice Consul General G. E. Chamberlin, of Singapore, reports that the output of cultivated rubber in the Federated Malay States for the first five months of 1909 shows an increase of 72.5 per cent. over the same period of last year. The production during the first five months of 1909 was 1,976,898 pounds, as against 1,142,084 pounds during the first five months of 1908.

We have received a copy of the Official Guide and Route Book of the Professional Chauffeurs' Club of America. The book, which is bound in flexible leather covers, contains numerous touring routes in all parts of the East and the Middle West, a list of official hotels and garages (not very extensive), and a list of the officers of the club.

## Commercial Applications.

## The Taxicab Business in Detroit. By F. E. Watts.

This summer is the first season that taxicabs have been operated to any great extent in the city, so the business is not yet old enough to furnish any conclusive data as to what its future will be. Those who have been interested enough to look into the matter, however, appear to think that good profits will be realized if too many companies do not enter the field. The two companies actively engaged in the operation of cabs both plan to put more vehicles in service in a short time, and at least one new company will probably be started in the near future.

#### THE DETROIT TAXICAB COMPANY.

This is the oldest and largest taxicab operating company in the city. It is the successor of the Auto Express Company, which formerly operated a delivery service that was fully described in these columns. The development of the auto livery business in the city caused the management of the Auto Express Company to investigate the situation. They concluded that there was more money in carrying people than parcels, so discontinued their express business and established a rather extensive livery service. When the taxicab business first began its rapid growth in New York and some of the larger Eastern cities a few taxicabs were placed at the leading hotels. These proved profitable, and the number was increased. At the present time twenty-six machines are in service, and nineteen more will be added in a short time.

The offices and garage of the company are located on Randolph street, a few blocks from the business centre and from the leading hotels. Up to the present time this building has also accommodated the Detroit agency for the Oldsmobile, but as the new Oldsmobile Garage is nearing completion the sales and garage business will be moved to the new location in a short time.

These changes are at present so occupying the attention of Manager Scrimger that the writer has been unable to get the details of the business for this article. These details will probably appear in an early issue.

A few details of the equipment may be mentioned. The cabs are all Oldsmobiles, equipped with front wheel driven taximeters. Fisk tires and demountable rims are used. The company have also been trying out solid rubber tires and spring wheels made by a local company. Both a hacking and a stand business are conducted. All repairs are made in the company's own shop.

#### THE TAXI-CAB SERVICE COMPANY.

This company is better known to the general public as the "Yellow Bonnet Taxicab Company" on account of the distinctive color which the bonnets of their cabs are

painted. The cabs are Chalmers "30" limousines, and, although not designed for this work, are said to be giving most satisfactory service. Fifteen of them are in operation at the present time. Both a hacking and a stand business are conducted. There are some six stands, located at the principal hotels. Cabs are also sent to the depots to meet all trains and to the numerous boats which arrive from all ports on the Great Lakes.

For one or two passengers the rates are 30 cents for the first half mile or fraction; 10 cents for each quarter mile thereafter, and 10 cents for each six minutes waiting. For three, four or five passengers the running rates are increased to 30 cents for the first one-third mile or fraction, and 10 cents for each one-sixth mile thereafter, the rate for waiting remaining the same. No charge is made for idle mileage in answering calls from points within I mile radius from the City Hall, but when cabs are ordered from outside the mile circle a charge of 20 cents for each mile or fraction thereof, from the mile circle to the point ordered, is made under the heading of "extras." Fisk tires and rims are used under a maintenance guarantee on the basis of 3 cents a mile for each cab. The daily mileage of a cab varies widely. But the superintendent, Mr. Gareau, stated that he believed that the average would be about 70 miles.

During the past few months the business has developed into a twenty-four hour rush, but as the company has not been engaged in the service for a year yet no prophecy can be made as to what the demand will be during the winter months. A considerable business is done at special monthly rates, and quite a number of the customers have monthly bills of between \$300 and \$400. Plans for extending the business are under way, but have not yet taken definite form. It is thought, however, that Packard and Fiat chasses will be used when more cabs are put in service. Minor repairs are made at the garage.

#### A RETIRED COMPANY.

A call at the large new Woodward avenue garage, occupied by the Postal & Doherty Auto Company, disclosed the fact that they had discontined their taxicab service. At one time they ran five cabs. These cabs were put on as an experiment, and various makes were used, including a White steamer, a Maxwell and an Aerocar. The business was found to pay well, and calls were received during the entire twenty-four hours. It was practically impossible to get good drivers, however, and a few accidents occurred which cut down the profits. The management became convinced from watching the manner in which the cars were handled that the item of repairs would be considerable as time went on, so they decided to discontinue the business. At the time of the writer's visit their cabs had been out of service some months, but they still had about forty telephone calls for cabs each

At the present time the problem of get-

ting good drivers, men who will handle their cabs carefully, seems to be the greatest difficulty in establishing a profitable taxicab service in this city. In this connection Mr. Gareau told the writer of one driver who had increased the daily receipts of his stand from about \$5 to nearly \$40 a day, and who at the same time had decreased the repair bills on his cab in something like an inverse proportion.

#### Taxicab Business in the South.

While the automobile business in the South has proved very lucrative, the taxicab business is practically in its infancy, especially in Tennessee, where the business is limited to three cities—Nashville, Chattanooga and Memphis. However, the companies operating the machines are well pleased with results.

The State of Tennessee requires every automobile to be listed with the Secretary of State, for which a fee of \$2 is required, and the city ordinances also impose a nominal license fee. The fees for licenses are, therefore, of little moment, so that individuals or firms with small capital may engage in the business with profit, and doubtless the next year will see many more companies engaged in this business in Tennessee.

#### NOVELTY ATTRACTS

In practically every line of commercial endeavor, if something new or novel is introduced it at first draws patronage by reason of its novelty. If in the meantime the practicability of the innovation is demonstrated an established trade results, and the business is listed among the successful ventures. So far the taxicab business in Nashville promises to be so listed, and the Nashville Taxicab Company, which began operations three months ago, is making arrangements to quadruple its "rolling stock."

The municipal authorities make no very burdensome requirement. A license of \$10 for each cab is charged and \$12 per year for automobiles in the draying business. No machine may be driven within the business district at a rate exceeding 8 miles an hour, or over the streets in the residence section at a rate exceeding 25 miles an hour. Otherwise there are trouble and fines, which run from \$10 for a first offense to \$25 for the second and revoking of the license for the third offense.

The introduction of taxicabs in Nashville was attended with the usual rush for rides. The society element especially welcomed the taxicabs, for in days gone by ladies had been accustomed to paying from \$3 to \$4 for a cab of the "horse" variety in which to make calls and attend the various social teas, card parties, etc., and the reduction in social expenses was very pleasing. The novelty still clings and the business is good—so good, in fact, that the cabmen are on the anxious seat, with "fares" getting fewer and fewer all the time.

#### SOMETHING OF THE BUSINESS.

The Nashville Taxicab Company was chartered under the laws of Tennessee and capitalized at \$30,000, with E. C. Lewis, D. S. Williams, George E. Bennie, J. S. Frazer, George Frazer, Henry Frazer and Banks Bennie incorporators. J. S. Frazer is president, D. S. Williams vice president and Banks Bennie secretary and treasurer. The company maintains a garage at 112-114 Third avenue South, in which the taxicabs are stored and repaired, although the repairs have been of a very insignificant nature. The office of the company is in the same building.

The company operates the Sultan make of cars, manufactured by the Sultan Motor Company, of Springfield, Mass., the cars being 12 horse power, French rating. At the time of writing only three cabs are being operated, but within the month six others which the company has ordered will be placed at the command of the traveling public. The taxicabs are operated from public cab stands—one at the corner of Fourth avenue and Church street, another at Eighth avenue and Church street and the other at Fourth avenue and Cedar street, all taxicabs being in front of the leading hotels of the city and in the business district.

The machines have pneumatic tires and the Stepney spare wheel is used.

The rates are the same day or night. When the flag is lowered on the taximeter 30 cents appears, and this pays for the use of the cab until service to that amount either in driving or waiting has been rendered. Thereafter the taximeter registers to cents for each quarter mile or for each six minutes of waiting. For the first half mile or fraction thereof a taxicab costs 30 cents. If the taxicab is driven through a toll gate the passenger must pay the toll, although such a contingency will not arise in Davidson County, where all pikes and ferries are free. While the cabs or touring cars may be engaged by the hour, all such arrangements are made with the officers of the company, the regular rates being charged as are in vogue at the other garages.

Baggage, such as handbags, grips and suit cases, which the passenger may carry inside the cab, are not charged for, although baggage carried outside is charged for at the rate of 20 cents for each package.

The cabs will be prompt!y dispatched day or night on call to any address within 2 miles of the garage free of charge, but where the distance is over 2 miles a charge of 20 cents is made. When the cab is dismissed at any point over 2 miles from the garage, a charge of 20 cents is made for the return service.

The driver is charged with all amounts registered, and is not permitted to make any reductions therefrom, but will if required give a receipt for the amount paid. If the cab is disabled the service up to the

time of such disablement is charged for. A cab ordered and not used must be paid for up to the time the driver is dismissed, including sending charge of 20 cents.

#### NO DIFFERENCE FOR CAPACITY.

Whether one passenger or four occupy a taxicab the charge is the same, and for this reason ladies with invitations to a party living in the same neighborhood have been enabled to cut down "transportation expenses" considerably, and at the same time go to every party in a taxicab, whereas before, except in threatening weather, the street cars were used. The taximeters are driven from the front wheels.

The Nashville Taxicab Company has no maintenance contract with either tire manufacturers or manufacturers of cars, all repairs being done in the repair department of the company's garage.

The drivers are paid a percentage of the earnings. The daily average mileage of each car is seventy-five. Oil is furnished the drivers free, but gasoline is charged for at the rate of 12 cents per gallon.

While the patronage has been good all along, the officials of the company state that the most revenue comes in between 10 o'clock at night and 2 o'clock in the morning. On Sundays the cabs are busy most all the time.

In Nashville there is an interesting system in the operation of the street cars which plays into the hands of the taxicab company. The street car company has what is termed the "line up," all of the cars on the system being lined up at midnight in the transfer station, one car going out each line, and none after that until the next morning. This may be responsible for the increased patronage of the taxicabs, as many persons miss the midnight car, and have to get home. Whereas formerly the cabs were used, the taxicab now takes its place as it is faster and cheaper.

SPLENDID PUBLIC ROADS.

The man with an eye for investment would naturally ask about the population first and the condition of the roads next. While Nashville has approximately 125,000 inhabitants, they are not all of the class that can afford taxicab rides. In the matter of roads, however, the city is perhaps more fortunate than any city of its size in the South. Nashville is located in the limestone belt, and as a result the materials that enter into roads of the substantial type are easily accessible, and this fact has been noted by tourists who have made cross country runs through this section, the same being most favorably commented upon in their accounts of tours through the South. With bad streets and a big repair account there is scarcely much encouragement to the man in the taxicab business; in fact, the same causes have operated against the owner of machines for pleasure in many cities and towns, and it may be that the fact of Nashville being so favorably located in this respect is responsible for over half the automobiles in the State being owned by residents of this section.

## Motor Cab Items from Allentown, Pa.

There are now three companies operating motor cabs in Allentown, Pa. The Allentown Taxicab Company have recently moved to their new garage at 113 South Seventh street. They have seven cabs in service, most of them being Fords. The company's rates of fare are as follows: Day rates, in effect from 6 a. m. to 6 p. m., within city limits, for one or more persons direct to one address, 25 cents per person; for each five minutes of waiting, 10 cents. Night rates, for one person to one address, 40 cents; for two persons to two addresses, 70 cents; for each additional person, 30 cents; for each five minutes of waiting, 10 cents. For calling or shopping, a flat rate of \$1 per hour, or fraction thereof, is made between the hours of 6 a. m. and 6 p. m., while cars are let for continuous service for one to four persons at \$2 for the first hour and \$1 for each additional hour or fraction thereof. The company also makes special rates to a number of points outside the city.

The Maxwell Taxicab Company, whose garage is located at Church and Baumer streets, operates five Maxwell taxicabs and are said to be doing the greatest amount of business in Allentown at the present time. E. A. Krause is the proprietor of the service. The fare in the city is uniform, 25 cents per passenger per trip, day or night. The rates by the hour are \$2 for the first hour and \$1 per hour thereafter. The company also has a number of five passenger touring cars, which can be hired by the day or hour.

The Hamilton Auto Company, 943-947 Hamilton street, Allentown, operate four Ford taxicabs and charge the same rates as the above mentioned companies. They occupy the whole Roller Rink Building, which affords a floor space of 290x65 feet.

It will be observed that all of the above mentioned companies operate on a hacking schedule of so much per trip, and do not use taximeters.

## More Municipal Cars for Milwaukee.

Three new municipal cars will soon be purchased by the city of Milwaukee, if the council committee recommendations are adopted. The water works and the health department will each be given a touring car, while a roadster will be added to the automobile equipment of the fire department. It is the intention of Chief Clancy to provide all assistant fire chiefs with roadsters to replace the two horses each maintains. It is probable that all city owned cars will have the name of the city and department painted on the sides. The purpose of this, it is said, is to avoid the use of municipal automobiles for private uses. This evil has already taken root in Milwaukee. Alderman Stern, father of the ordinance, calls attention to the fact that the President's steam car and many Eastern municipal cars are so designated.

## Pennsylvania Railroad to Discard Horses.

It is reported that the Pennsylvania Rail-road has decided to substitute electric trucks for all of its horse trucks, and will begin the transformation of its service in connection with its shops at Altoona, Pa. At present the question is being studied whether it is best for the company to build the vehicles themselves in their shops at Altoona, or to have them built by outside firms making a specialty of such work. The company owns a large electric plant, so that the current necessary for charging need not be obtained from a central station.

#### Taxicab Service in Reading, Pa.

The Reading Taxicab Company, the only concern of the kind in the city, now operate seven Franklin cabs and two touring cars. Rates are 30 cents for the first half mile, 10 cents for each additional quarter mile, \$3 per hour, and \$1 per hour while waiting. Touring cars rent at \$3.50 per hour.

The cars are stored and cared for at the garage of the Reading Automobile Company, 28 South Fifth street.

#### Commercial Notes.

An automobile line for carrying the mails, passengers and freight is to be established between Las Vegas and Nelson, Cal.

Newton & Woodside, Buffalo, Wyo., are operating a steam car in a public service between Buffalo and Sheridan. The roads in the vicinity are very mountainous.

Automobile stages are being used in the Palo Verde Valley, Cal., for conveying land seekers to the tracts for sale. A trip that formerly required two days is covered in five hours with the autos.

Richard Nye, Santa Barbara, Cal., will shortly inaugurate a sightseeing service in Santa Barbara with two sightseeing cars. One will be operated between Santa Barbara and Montecito, while the other will run to Hope Ranch and Goleta.

The Municipal Hospital in Philadelphia has purchased its first motor propelled ambulance, which was built by the Knox Automobile Company, of Springfield, Mass. The car is equipped with a standard ambulance body, with all conveniences, including electric lights, folding seats, etc. The weight complete is 3,600 pounds.

Charles Ilten, Portland, Ore., will establish a taxicab service in that city with Franklin 18 horse power taxicabs, of which he has bought twelve through the Portland agency. It is expected that all of these cabs will be in operation by November 1. Mr. Ilten will operate the cabs from his new garage at Fourteenth and Burnside streets.

The trustees of Queens County, N. Y., who have charge of the Public Library system, have included in their budget for the coming year an item of \$2,500 for an automobile and \$1,200 for a chauffeur. The

automobile is to be used for transferring books between the sixteen branches and the main library, and to carry the trustees on tours of inspection.

The Motor Transfer Company at Fort Wayne, Ind., has placed four Cadillac taxicabs in service between the depots and hotels, and also for other trips around the city.

The Seeing California Traffic Bureau, of Los Angeles, Cal., has established a service in Pasadena in charge of C. A. Hubert. The Pasadena branch conducts a service from the Hotel Green to Orange Grove, for which trip a 5 cent fare is charged, and also a round trip of the city, including the ostrich farm in South Pasadena, for which the fare is 75 cents.

Chas, Day, of Navajo and St. Michaels, Ariz., will open a garage in Gallup, N. M., and establish automobile services from Gallup to St. Michaels, Fort Defiance, Ganado and Chin Lee; also from Gallup to Tohatchi and Chrystal, and from Gallup to Zuni and the various posts to the South. Mr. Day has four high powered cars, including a seven passenger Pope-Toledo, which he will employ in the various services.

## Philadelphia Garage Owners Organize.

The Philadelphia Garage Association has been organized during the past few weeks. and is said to already embrace 60 per cent. of all the garages of the city. The main object of the organization is said to be to correct the "joy riding" and commission evils. As long as the garages were unorganized it was practically impossible to put a stop to joy riding, because if an attempt was made the chauffeurs would take their cars to other places where they were allowed to take them out whenever they pleased. To incur the enmity of these chauffeurs practically meant bankruptcy for the garage owner. The new organization also plans to conduct an employment bureau which will maintain a register of chauffeurs. Owners of cars may there secure drivers whose records show them to be honest, careful and sober men against the payment of a small fee. Owners storing cars in the garages of members of the association have the privilege of examining the records of applicants for positions free of charge. The means by which the association hopes to defeat grafting and joy riding are explained in the bylaws which contain the following two paragraphs:

"A member (garage) found guilty of paying a commission to a chauffeur shall pay into the treasury the sum of \$25, and upon failure to pay this fine promptly shall be reported to the board of directors, and may be suspended by them.

"Each member shall, at the request of an owner, send the owner a car check sheet showing day by day the time his car entered and left the garage during the preceding month."

#### The Selden Case.

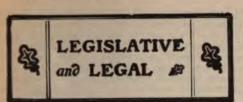

Proceedings in the Selden case are now resting, pending the entering of the decree. As the suit asks for an injunction to restrain the defendants from infringing the patent and for damages for the infringement already committed, it is expected that the decree will order the issuing of injunctions. Defendants then will have thirty days in which to file an appeal to the United States Circuit Court of Appeals. Ordinarily, this is the highest court to which a case of this kind can be carried. A petition can, however, be made to the United States Supreme Court, and if this court finds that the case involves questions which have never before been decided by it, it may take the case up. It is stated that very many such appeals are declined each year, but the Selden case admittedly involves novel points, and it would not be surprising if it were taken up by the Supreme Court.

As to the line of action that will probably be taken against other infringers, nothing can be learned at present. This matter will probably come up for decision before the executive committee of the Association of Licensed Automobile Manufacturers. The members of this association, as licensees under the patent, are interested in seeing it upheld, and it is understood that the association virtually conducted the litigation, although the complainants named in the suit are George B. Selden and the Electric Vehicle Company, now the Columbia Motor Car Company. Mr. Selden is the patentee and owner of the patent, the Columbia Motor Car Company are sole licensees under the patent, and the members of the Association of Licensed Automobile Manufacturers are sub-licensees.

It is to be presumed that aside from conducting the case in the Court of Appeals with vigor, the complainants will immediately take steps to enforce the rights conferred upon them by the patent against all other infringers. Suits have already been brought against some thirty or forty manufacturers, and whether preliminary injunctions are applied for on the strength of the decision remains to be seen.

#### Around Long Island Tour.

The New York Automobile Trade Association will hold its second annual "Around Long Island Tour" on Tuesday, Wednesday and Thursday of next week. Last year the trip was completed in two days, the run to Montauk Point being made on one day and the return the next. The start on the first day will be at Columbus Circle, New York. and the first day's destination is the Orient Point Inn. The second night's stop will be at the Irving Hotel, Southampton, and on the evening of the third day the tour will end at the Automobile Club of America in New York. The total length of the route is 335 miles. The roads are in good condition almost all the way, and if last year's event is a criterion the tour will be more an outing than a contest.

#### The Selden Decision.

One of the most celebrated cases in the annals of patent ligation was decided in the lowest court last week, when Judge Hough at New York sustained the Selden patent. The case against the Ford Company had been pending for six years, and the long delay before a decision was rendered caused interest in the case to wane, to a considerable extent, in recent years. It probably also lulled many of those interested in the outcome into a false feeling of security. The importance of the decision makes it worth the while to briefly review the litigation. The entire automobile world is interested in the matter, because not only the manufacturer of an infringing article but also the seller and user thereof are liable to the inventor or the owners of the patent.

The Selden patent, of which infringement was alleged, is No. 549,160, which was issued to George B. Selden, of Rochester, N. Y., November 5, 1895. Application for the patent was made as far back as 1879 (on May 8), the issuing of the patent being delayed by the applicant by making changes in the claims or taking such other steps as are allowed by the patent law. The broad claims of the patent were first drawn attention to by the Commissioner of Patents in his annual report for 1895, and the claims were printed in a special article in THE Horseless Age of December, 1896. Although the existence of the patent was thus early brought to the attention of the motor vehicle industry, no heed was given it by experimenters during the next few years, and no decisive steps appear to have been taken to compel its recognition by the industry until the patent was sold to the Electric Vihicle Company, of Hartford, Conn., which was in 1900.

Suit for infringement was then brought against the Winton Motor Carriage Company, of Cleveland, Ohio, at that time the principal American makers of gasoline automobiles in the United States, and their New York agents. Defendants entered a writ of demurrer, claiming that the patent was void for lack of patentability, but this was overruled on November 9, 1900. The Winton Motor Carriage Company some time later acquired a license under the Selden patent. The claims under the patents were then strongly urged, and about 90 per cen, of all American manufacturers of gasoline automobiles were induced to take license under the patent, and formed the Association of Licensed Automobile Manufacturers in New York in May, 1903. Under the terms of the license agreement each member of the association has to pay a license fee on the selling price of his product, of which nearly equal parts go to the Electric Vehicle Company and the association, respectively. The first action under the patent taken by the association was against Smith & Mabley, agents for French Charron cars. This suit was brought in April, 1903, but was settled out of court.

Among the few important manufacturers at the time the Licensed Association was formed, who did not join, was the Ford Motor Company, of Detroit. A suit was brought against the company and against its New York agents in October, 1903. It is this suit which has now been decided by Judge Hough. The complete opinion, with the exception of foot notes, follows:

The application for the patent on which these actions are based was filed in 1879—or more than sixteen years before the grant was made.

The principal claim in suit (No. 1) reads thus:

"The combination with a road locomotive, provided with suitable running gear, including a propelling wheel and steering mechanism, of a liquid hydrocarbon gas engine of the compression type, comprising one or more power cylinders, a suitable liquid fuel receptacle, a power shaft connected with and arranged to run faster than the propelling wheel, an intermediate clutch or disconnecting device and a suitable carriage body adapted to the conveyance of persons or goods, substantially as described."

The second claim varies from the first only in requiring the "suitable carriage body" to be "located above the engine," while the fifth claim sets forth substantially the same combination, but specifically describes the engine as comprising a plurality of cylinders with "pistons arranged to act in succession during the rotation of the power shaft."

These three claims are alleged to be infringed by all the defendants.

This statement of complainants' position seems sufficient to show that the subject matter of these suits is the modern gasoline automobile. The defendants are severally the manufacturer, seller and user of the Ford machine (a well known American make) and the maker and importer of the Panhard, a celebrated and typical French product. If these defendants infringe, it is because complainants own a patent so fundamental and far reaching as to cover every modern car driven by any form of petroleum vapor, and as yet commercially successful.

Such a claim lends interest even to such a record as is here submitted, and requires careful examination, to the end that the parade of forces in this court may at least serve to shorten and simplify the certain conflict in the appellate tribunals.

Upon one question of law all counsel are agreed—the patent claims under consideration are all for combinations; there is, of course, no agreement that the combinations set forth are patentable, and none as to the interpretation of their language if valid at all, but there is no denial that in form nothing but combinations are claimed.

This is emphasized because it seems to open and simplify the discussion. Selden does not pretend to have invented any new machine or combination of matter in the same sense that Whitney invented the cotton gin or Howe the sewing machine. He does not in application or claim specify any one mechanical device for which in branch of art a prototype cannot be found; there had been and were in 1870 running gears, propelling wheels, steering mechanisms, gas engines, etc., of many forms, and his patent covers no one form of any of these parts of his "road locomo-tive." He does assert that he released modified, co-ordinated and organized the enumerated parts (including the usual mechanical adjuncts of each part) into a harmonious whole capable of results never before achieved, and of an importance best measured by the asserted fact that after thirty years no gasoline motor car has been produced that does not depend for success on a selection and organization of parts identical with or equivalent to that made by him in 1879. If this be true, it may be held at once that in such a mental operation and such an important result therefrom, invention, and that of a high order, undoubtedly does reside. Where Bradley, J., declined definition, he would be a bold man who tried it, but I am sure that invention is easily discernible as that which vitalizes Selden's selection, and if that selection and its results have been truly described.

Broadly speaking, the defense in these cases rests on a denial of the truth of the foregoing summary of Selden's performance, which denial has two parts: (1) Selden did not do what he now asserts, and (2) defendants' combinations differ from Selden's, being neither identical nor equivalent.

In considering what Selden did, and the meaning of the words in which he described and claimed his achievement, it is to be remembered that whether his combination constitutes invention and whether it possesses novelty and utility are primarily questions of fact, as to which the very grant of the patent raises a presumption in favor of complainants, while the demurrer decision (in Electric Vehicle Company vs. Winton Motor Company, 104 F. R. 814) is here controlling authority to the effect that on its face, plus all matters of which the court can take judicial cognizance, the patent is valid.

To ascertain, therefore, how far defendants have succeeded in meeting the burden of proof, which in all matters of fact lies on them, it seems fair to begin by discovering from all the evidence what was the state of the art when Selden filed his application in 1879.

But what is the art as to which this inquiry is to be made? On this preliminary point it seems to me that defendants' testimony and argument have taken too wide a range, or at least laid undue emphasis on matters of little moment. This invention does not belong to the steam engine art, nor that of any engine, regarded alone; nor is it fruitful to examine carefully the development of traction engines, whether primarily designed to haul "trailers" or transport persons and goods over their own wheels. Boats also, and tram cars, propelled by engines of any kind furnish but a limited field for useful investigation; the inquiry is, how stood art (and science, too) in 1879, in respect of a self propelled vehicle with a considerable radius of action over ordinary highways, and capable of management by a single driver, and he not necessarily a skilled engineer?

Or (to use a phrase frequently occurring in the testimony and exhibits) what was known of the "horseless carriage" industry in 1879, either at home or abroad?

The answer given by the evidence is entirely plain—there was no such industry, the art existed only in talk and hope, no vehicle even faintly fulfilling the requirements above outlined had ever been built, and there is no competent and persuasive evidence that any experiment had ever moved a hundred feet, or revealed an organization warranting the expectation that it ever would do so.

Some examination of the kindred arts, above alluded to, serves to explain this situation. For more than one hundred years steam, as a prime motor, had dominated the world of mechanic art. Steam as the power for a self propelled road vehicle had been exhaustively worked over, and patents obtained, from Trevithick (British 2,599 of 1802) to Monnot (U. S. 197,485 in 1877), and the result was the traction engine; it made no difference whether it carried passengers or hauled freight, the actual type and only type was a boiler on wheels, of enormous weight, slow speed and small radius of action.

But the numerous experiments with steam road wagons had (however meagre the success attending them) served to make known to that wholly ideal and fictitious person, "the man skilled in the art," something of the organization of any road vehicle capable of operation by a small crew. Steering mechanism operated by wheel before the driver, independent turning of the fore wheels, the chain drive, as well as beveled gear connection between power and driving shafts, devices for disconnecting power from running gear and letting engine run free, plans for brake control of quite

a modern sort, and stowage of motive power in parts of the vehicle remote from passengers—all had been practiced or suggested. From patents and publications scattered over two continents and more than two generations there can be reconstructed (and defendants have done it on paper) something that is very far from even a good theoretical road wagon, but which does contain most of the elements of Selden's combination—and this represents the art, known to the man skilled in both theory and practice, a good mechanic, with a scientific education and widely read in the technical literature of all civilized nations, by whose incredible knowledge the achievements of patentees are so often measured.

Obviously if a fairly good road wagon cannot be reconstructed in 1909 out of materials so industriously collected from the scattered knowledge of 1879, it is desirable to ascertain whether there then existed some one lack, whether the art then required some one thing which was wholly missing—in order to produce a practical self propelled road vehicle.

It seems to me plain that there was such lack, and it may be stated in the language of one of the numerous inventors who procured long and elaborate patents relating to road locomotion, and never (so far as this record shows) did anything more.

Savalle (French 77,644 in 1867) says in a certificate of addition dated March 16, 1869:

"I have tried to apply to road locomotives several motors operating by air expanded by the heat produced, either by the explosion of the gas, or by air forced over a metallic surface, heated by coal or other combustible, or also by petroleum.

"These divers forms of motors apply perfectly when it concerns the traction of omnibuses or other large vehicles of this kind; but when it is necessary to apply this kind of locomotion to light carriages, only carrying one to six persons, or to drive a velocipede, these means become impracticable by the large space which they require."

The lack, the something that had to be supplied before it was worth while to organize the vehicle was the engine. Steam had thus far failed, and this record seems to show that at about the time Savalle wrote the gas engine as a road wagon motive power began to be mentioned in serious publications, and patent specifications.

Savalle was much mistaken in asserting that any of the assorted motors mentioned by him had successfully driven an omnibus or any similar conveyance, but he early hinted at the truth that in some form of motor, actuated by a product of petroleum, would be found, if not the immediate solution of the problem, at least the missing element that would make the solution sure.

This missing element Selden avers he discovered, and it follows that over his engine the conflict in these cases has raged through several volumes. In trying to ascertain, however, the status in 1877-9 of engines in any way resembling Selden's the court is fortunate in having in evidence a book entitled "The Gas Engine," published in 1885 by Dugald Clerk, who has also testified with admirable clearness as an expert for complainants.

It appears that the materials for this book were gathered during the very period of Selden's experiments, while so completely has Clerk furnished a classic on the history of the gas engine art that even counsel who sharply criticise his evidence support their arguments from his book to such an extent that it is not too much to say that many chapters thereof could be reconstructed from their briefs.

In 1879 "internal combustion" engines were well known, and had reached a considerable degree of commercial success—despite the fact that the reasons for their success or more frequent failure were very ill understood.

The fact that fuel might be burned in the engine cylinder itself, that such burning (if of gases) produced an expansion thereof, and that such expansion might be utilized by allowing it to push the piston, was and is the basic proposition.

This knowledge had produced the Lenoir engine in 1860 and the Hugon in 1865, constructed in close adherence to the steam engine of the day, and giving less than one horse power per ton of weight. Both normally used illuminating gas at atmospheric pressure.

The Otto free piston engine of 1867 marked an advance in effectiveness, but no form of gas engine had yet appeared, which (so far as shown) was more than suggested as the propulsive power of a road wagon.

In 1861 Million, and a year later Beau de Rochas, Siemens and others pointed out the advantage of compressing the gaseous fuel before ignition in order that the expansion should be both greater and quicker, with the greatest possible pressure at the beginning of the expansive movement; and in 1872 Brayton in America, and in 1876 Otto in Europe, introduced compression engines, the latter with great commercial success.

The change from a gaseous fuel burning at atmospheric pressure to the same 'fuel burned under compression was a change of kind, for, though formed of the same chemical elements, the compressed fuel possessed a power when used by men who live by breathing atmospheric air, that uncompressed and commercially possible gases did not and could not exert in any non-compression engine even as yet imagined. It therefore seems clear that the phrase "compression type," as applied to internal combustion engines, is reasonably indicative of a class, and appropriately describes an unmistakable and invariable species of the genus gas engine.

The evidence is persuasive that the increasing success of the gas engine, produced in the middle '70s of the last century, repeated dreams (they are no more) of applying a gas engine to a road wagon.

In 1877 Rosenwald (French 116,871) made a picture of a brougham having an Otto free piston engine perched in an apparently insecure position between passenger and driver. His is a paper patent only, and is in my opinion clearly shown to be inoperative for reasons of which one only may be mentioned—the most improved type of Otto engine then known weighed over half a ton per horse power; he did not use the most improved type, and did not propose any improvement or modification which would have prevented his brougham from going to pieces at the first jar of his motor. This patent is the suggestion nearest to Selden, and is mentioned for comparison hereafter.

Although by 1870 internal combustion engines had separated into the compression and non-compression classes, they were (and still are) all known as gas engines, irrespective of the condition of their fuel immediately before the work of preparing it for combustion begins. The term originated doubtless when coal gas was the only gaseous fuel known-but the vapor of petroleum or of any product thereof (gasoline or petrol) is just as much a gas as another, and thirty years ago there was, and there is now, no distinction generally obtaining between engines whose fuel as ordinarily purchased is coal gas, and those using gasoline or crude petroleum, provided that what ultimately burns in the cqlinder is that vapor substance, "capable of expanding indefinitely"which is gas.

But if the substantial difference between compression and non-compression engines was known and recognized, certain other terms of art which have been far too much used in this litigation were non-existent in 1879. A great superstructure of argument has been built upon the difference between 'constant pressure" and "constant volume' gines. These terms appear to have been devised by Mr. Clerk, and first used in his book before alluded to, as convenient phrases useful in studying the operation of engines, and classifying their phenomena. The terms are instructive, as is the separation of nouns into declensions and verbs into conjugations, but much of the argument about the words attaches an undeserved importance to them. In all internal combustion motors the result of expanding the burning gaseous fuel is to drive the piston; that is, the cylinder chamber in which the expanding gas is confined gives way on the piston side (so to speak). If the piston head offers no more resistance than will permit it to move under the expansive force produced by the initial compression alone, evidently since the piston moved under that pressure, it will be maintained to the end of the stroke, the expansion produced by ignition serving to keep up that "constant pressure."

If, however, the compressed charge must be ignited before the piston moves, then whatever volume thereof is introduced into the cylinder increases (by combustion) its pressure on the piston head, before the engine operates, and the machine is described as "constant volume."

In both phrases "constant" refers to condition, at the instant piston movement begins, compared with that at the moment the fuel charge is inserted. If between the two moments pressure increases, then the volume is constant; while if volume increases, pressure is constant.

These conditions are theoretic. If in a constant pressure engine the load or piston resitance is suddenly increased, the expansive power produced by compression alone may not start movement before ignition or explosion-and accordingly (if too much importance be attached to phrases) the type of engine has changed. Of course nothing of the kind has occurred-the relation of piston head to cylinder walls relative to time of explosion has changed, and it may nowadays (in many engines) be changed at will to suit load and speed by throttling and by timed ignition. These variations have been observed in all the engines testified about in this case. They occur, or may occur, in all compression engines, and are no more significant of specific or generic differences than are variations in rapidity of breath in different men, or in the same man at different times.

From this attempted outline of the knowledge and achievements of 1879, it seems to me that the way was singularly clear for anyone who would really produce the thing described in Selden's first claim.

Success is never anticipated by any number of failures, and when it is clearly kept in mind that what Selden claims is a combination, and not any one of its elements, the defendant's references to prior patents and publications may be thus finally disposed of so far as this court is concerned.

Much has been said concerning this inventor's personality and there is some importance therein as showing the likelihood of his comprehending his own experiments, and telling the truth about them. The record shows him always interested in mechanical pursuits, receiving an appropriate education for the theoretical side thereof, but not himself a skilled practical mechanician.

His application for a patent on a rubber tire wheel made in 1869 is significant and interesting, and, in view of quite recent litigation in this circuit, instructive. Taking his evidence in connection with his letters and notes, he is shown especially attentive to traction problems from his early manhood. I am persuaded that he carefully studied Brayton's engine and understood it practically-but his knowledge of the theory of thermodynamics seems fairly illustrated by a remark to his workman Gomm when his original engine turned over: "We have struck a new power." There is no satisfactory evidence that before application filed he knew thor oughly anything of Otto's compression engine. All this was not a very complete equipment: but he had the true inventor's enthusiasm, and for more than five years (as the Chief Justice said of Morse-15 How 108): "He pursued these investigations with unremitting ardor and industry, interrupted occasionally by pecuniary embarrassments."

When he was ready to file his application he had completed and experimentally operated one cylinder of a three cylinder engine of the general type Brayton has patented in 1872 and 1874. He intentionally built a plurality of cylinders, to obviate or minimize the necessity for a flywheel, he produced an enclosed crank case (which immediately reduced weight to an enormous extent) and used a small piston with a short stroke (which made possible the speed that would compensate for the loss of piston head area).

This engine (with allowance for adjuncts Selden did not use), but (as experience has shown) should have used, weighed less than 200 pounds per brake horse power, as compared with over 800 pounds in the lightest form of Brayton's, and is capable of

over 500 revolutions per minute, as against less than 250 by any type of gas engine known, built or suggested in 1879.

These I find to be the facts regarding the engine built by Selden before application filed. He then caused to be made a model and mechanical drawing of his suggested vehicle and actual engine and submitted the same with specifications and claims

to the Commissioner of Patents.

Avoiding for the present the language of his original application, and the effect of the numerous changes therein during its many years in the Patent Office, was the thing fairly revealed by the model and drawings, and conceived under the circumstances above set forth—the embodiment of a combination patentable in 1879?

think the answer is emphatically yes; that which is not obvious to skillful men is usually (as remarked by Mr. Clerk in his evidence) invention, and certainly what Selden shows in his model, and by the drawings which have remained unchanged for thirty years, was anything but obvious. The inventive act is shown by comparing Selden and Rosenwald. If the latter's brougham had actually carried its engine, and traveled even a little, he might nevertheless (on defendant's own argument) have found his patent invalid by American law, because each part of his vehicle was doing just what it had always done, without any new operative law," while his engine in particular was the same motor which before it was applied to the brougham had perchance driven a lathe and might tomorrow do something else. Rosenwald might held a mere aggregator (however successful), but Selden's combination cannot be taken apart and each element recognized as something that had done the same thing or sort of thing before,

The adaptation of the engine alone was something never before attempted (so far as shown); such adaptation might have involved an infringement on Brayton, but that did not prevent Selden's combination from being strikingly new, useful if it would work, and eminently patentable.

To sum up what is shown to have been the mental concept embodied in 1879 by Selden's model and drawings—with Brayton's engine in mind he organized a new road vehicle; to be sure, he did substitute one old and well known prime mover (gas) for another (steam), but in so doing he devised and used an arrangement of Brayton's engine never before attempted, one that Brayton himself never suggested, made or patented, and without which the road vehicle was an impossibility.

This mental concept constituted invention, if capable of reduction to operation, and if any operative example (not all operative examples) thereof was shown by the parentee.

If this doctrine be admitted or found, defendants before attacking the operativeness of Selden's vehicle seek to limit the scope of the patent by asserting that the combination is not infringed by any vehicle whose engine is not substantially identical with that described in drawings and specifications—notwithstanding the language of the claim "liquid hydro-carbon gas engine of the compression type."

Thus it is asserted that since Selden and Brayton show a spray of petroleum mixed with and carried by compressed air into the combustion chamber, they do not show a true gas engine; that the use of a carburetor separate from the engine proper and producing gaseous mixture which it feeds to the engine is something outside the patent and avoiding infringement; that a water jacket being shown by Selden in a peculiar and unusual equivalent, or attempted equivalent, is something outside the combination, and when used by defendants differentiates defendants' engine and combination from anything that infringes; and that since Selden evidently shows in his drawings ignition by a constant flame, he is confined thereto, and cannot use electric ignition, while defendants by using the same do vary the combination.

I have already tried to show that Brayton's petroleum engine, Lenoir's illuminating gas engine, and an Otto machine driven by gasoline are now, and were in 1879, not only "gas engines" in the

sense that they all operate on the same scientific principles, but they were known as and called "gas engines" by those best qualified to speak.

To make gas in one place rather than another must be an immaterial variation where a primary patent (such as this by complainants' contention) is under consideration; water jackets were old in 1879, and had been used in many forms, and both flame and electric ignition had been used and were well known to gas engineers of the day, although in 1879 it seems to me that the flame method was by far more successful than the electric as applied to compression machines.

The force of these objections, based on the face of the drawings and specifications, as compared with the claims, depends on whether the patent is viewed as a primary or pioneer one, or the contrary, and this in turn depends on the state of the art at the time of invention.

The art I have attempted to describe at perhaps too great length, because upon its condition this whole litigation seems to hinge.

If I have correctly apprehended it, there was clearly room for a pioneer patent, and it must now be held that on its face and in view of the art, Selden's is such a patent. This means that Selden is entitled to a broad range of equivalents and this rule as applied here results in this crucial inquiry: Was Selden (or anyone else) entitled in 1879 to appropriate as one of the elements of any patentable combination a "llquid hydro-carbon gas engine of the compression type"?

I think he was, and so was any other inventor, but he was the first so to do. If this he true, then the use or disuse of any then well known mechanical appliance which will increase the efficiency, usefulness or commercial success of such combination, without changing what defendants call its co-operative law, is on the one hand open to Selden, and on the other will not free defendants from infringement.

Although there were in 1879 many liquid hydrocarbon gas engines of the compression type, there was not one which in its then form could be made an element (and the most important element) in a road wagon combination, and the radical difficulty was the same that Savalle had confessed to ten years before.

Selden (on paper certainly, whether actually will be considered later) solved that difficulty, and such solution gave him the right to claim broadly the thing which was the leading element in his invention—when used in his combination. Thirty years have passed, and counsel admit that no successful gasoline motor car fails to use a liquid hydro-carbon gas engine—of the compression type—with a short rapid stroke, and enclosed crank case, and a plurality of cylinders.

These are the very things which are at the foundation of success. To be sure (as will be considered more fully later) no very great degree of success can be reached without improvement over 1870 in carburetors, and electric ignition, and increase of knowledge concerning the respective mechanical possibilities of two, four and six cycle engines; the faster also the reciprocating parts of an engine move the greater the necessity of constant and abundant lubrication, and Selden's lubriis confessedly primitive, and great difference between any results Selden's most optimistic supporter can claim for him in 1879, and the successes of 1909, arises from increased compression, so that engine weight per brake horse power has now been reduced to about 10 pounds.

But these are non-essential, if, in 1879, Selden could lawfully use as an element in his patentable combination, the "compression type," or species of a whole genus of engines. As already stated, I think he could, and did, and further showed and made an exemplar of said "type."

Thus far the claims and specifications have been treated as though they were presented to the commissioner in 1879, in the shape they left his office in 1895. This was not the case; nothing remained in 1895 of the language of 1879 but the description of the vehicle and engine (and not all of that); the claims were reworded and the specification amplified many times, and usually after a rejection made or criticism offered by the examiner,

Selden did nothing by way of amendment or reply for about two years—the extreme limit of inactivity permitted him by these rules of Patent Office practice.

By these means he received in 1895 a patent for an invention of 1879, and in the meantime had never built a motor car, and never succeeded in getting anyone sufficiently interested in his theories to experimentally try them out with larger means and better mechanical ideas than Selden himself had.

During the later years of this period, and while Selden was in very leisurely fashion combating examiners who evidently had small conception of what was meant by light self propelling vehicles usable on the common roads, Duryea, Olds, and others in America, the Panhard and Peugeot companies (and many others) in France were experimenting with actual cars, and in 1894 a public race meet was held in France, whereat cars now as archaic in appearance as Selden's demonstrated that they actually could propel themselves from Paris to Rouen at about 12 miles an hour. The engines of some of them were modified Ottos, and 'liquid hydro-carbon gas engines of the compression type," and it must be found that when den's patent issued there had been developed engines answering to his phrase, which as a matter of history are not derived from his engine-that others reached his type without knowledge of him or his labors; indeed (while certainty is impossible), it is my belief from this evidence that Selden has contributed little to motor car advancement in the United States, and nothing at all abroad. As a matter of fact, I believe that nearly all the cars made in the United States when these actions began were modeled on French ideas, and used engines descended from Otto through Daimler, and not from Brayton through Selden or any other American. In short, this American patent represents to me a great idea, conceived in 1879, which lay absolutely fallow until 1895, was until then concealed in a file wrapper, and is now demanding tribute from later independent inventors (for the most part foreign) who more promptly and far more successfully reduced their ideas to practice.

But the patent speaks from the date of its issue, and unless Selden did something unlawful during his sixteen years' wrangle with examiners, or unless intervening American rights, available to defendants, sprang up while Selden was rewording claims—he is within the law, and his rights are the same as those of the promptest applicant.

Without prolonging discussion, it may be held briefly that Selden did not overstep the law. He did delay; he was not in a hurry. He could not get anyone to back him, and doubtless appreciated that if he was ahead of the times it was wise not to let his patent get ahead too. If he had gotten his grant in 1880, without a moneyed backer, the patent might and probably would have expired or nearly so before anyone saw its possibilities; and if the business world had seen them within seventeen years, that term would then so nearly have expired that Selden would never have been able to get to final hearing before it run out. At best, an accounting and not an injunction would have been his lot. The difference he may well have considered as a lawyer, and personally I believe he did think of it.

If he did not delay unlawfully, what intervening rights did he permit to spring up?

Remembering that Selden clearly showed a "liquid hydro-carbon gas engine of the compression type" in 1879, and actually manufactured one, I think it clear that his original claim was wider than any of those in suit.

The third claim as originally filed read thus:

"The combination in a road locomotive provided with suitable running gear and steering mechanism, of a gas engine, traction wheels, and an intermediate clutch or disengaging device, substantially as set forth."

It is true that throughout the original papers he speaks continually of "Gas Engine L." that being the alphabetical designation given his motor in the drawing submitted; but the claim quoted shows how wide was his original demand, and without further elaboration I hold with complainants that all subsequent changes of claim are in diminution or contraction of this first statement of invention.

The file wrapper, cross examination thereon, and argument concerning it form a bulky volume, but it seems to me sufficient to quote from the amendment of June 6, 1889, when Selden amplified his specification by inserting the following:

"I have succeeded in overcoming these difficulties by the construction of a road locomotive propelled by a liquid hydro-carbon engine of the compression type, of a design which permits it to be operated in connection with the running gear, so that the full carrying capacity of the body of the vehicle can be utilized for the transport of persons or goods, and which, by dispensing with skilled attendance and with steam boilers, water, water tanks, coal and coal bunkers, very largely reduce the weight of the machine in proportion to the power produced and enables me, while employing the most condensed form of fuel, to produce a power road wagon which differs but little in appearance from and is not materially heavier than the carriage in common use, is capable of being managed by persons of ordinary skill at a minimum of trouble and expense, and which possesses sufficient power to overcome any usual inclination."

And at the same time he put what is now Claim into substantially its present shape.

The language last quoted is in the final specification, it describes the thing which Selden conceived and pictured in 1879; and in 1889 the man skilled in the art, though he knew more than he did in 1879, did not know as much as Selden sets forth in the quoted words. It was still possible for the gasoline compression engine to be made part of a patentable road wagon combination. No one in the United States had passed, or even caught up with Selden--while foreign efforts have been fairly and attractively told by Mr. Krebs, of the Panhard Company. He quite fully depicts the history of meritorious and successful efforts in road locomotion apparently as ingenious as Selden's, and more vigorously pursued, but they did not begin until after 1879, and in 1889 were still clearly behind Selden's concept.

Defendants have advanced many other arguments based on the contents of the file wrapper.

Thus the original third claim above set forth declares a combination in a road locomotive, while the first claim in suit covers a combination with a road locomotive. The change is declared to be an abandonment of the original combination. It is further shown that some patent examiner rejected certain claims, referring to the Pinkus patent (supra), and thereupon Selden amended the claims and disavowed and disclaimed Pinkus. The argument based on this is that since Pinkus "co-operative law" is the same as Selden's, the disclaimer of Pinkus was in effect an abandonment of the very combination now relied on.

I have already indicated my view of the major premise of the last proposition, but these arguments, and many others of the same ilk, cannot prevail if it be true that Selden clearly showed in 1879 the thing he had invented. If so, he could rewrite the description of that thing as many times as the rules of practice permitted down to 1895. That such rewriting is all Selden did I believe to be true.

Defendants now urge that Selden's invention is inoperative. The one cylinder engine built by Selden on the three cylinder casting in 1877-8 was put in evidence as Exhibit 47. Thereafter the cylinders of Exhibit 47 were all bored out or rebored, new working parts fitted to them, and the engine put into a vehicle, the whole called Exhibit 89, completed in the winter of 1905-6, and constituting the first physical embodiment of Selden's patent. The complainant licensee, Electric Vehicle Company, also constructed a new engine from the patent drawings (Exhibit 132) and a complete vehicle (Exhibit 157).

Defendants aver that neither of these vehicles is a Chinese reproduction of Selden's drawings, and have devoted volumes of print to recording and arguing about the performances of Exhibit 80.

In my opinion Exhibit 89 as constructed was such Chinese reproduction, Exhibit 157 was not—

complainants having changed the water cooling device, used only electric ignition and made some other departures from the mechanical details shown in the drawings. But these variations were (as previously indicated) within the range of equivalents permitted to a primary patent.

The evidence on the subject of operativeness is the most flagrant example of unsupervised testifying I have ever seen or heard of.

Whether in 1905 Exhibit 47 was any better than scrap, whether Exhibit 89 would start on flame ignition, whether Exhibit 132 showed diagrams revealing volume or pressure constant, were perhaps interesting but unimportant questions. They raised a false issue over which months of time and volumes of print have been expended.

The serious and I think only question was and is whether a machine made in substantial conformity to drawings and specifications, without going beyond the range of equivalents permitted, was operative, even though rudimentary. Exhibit 157 answers to this description, and its performances may I think be thus summarized—it is a wretchedly poor car for 1905; there were probably as good, if not better, cars in 1895, but it is a marvel of invention for 1879—and that is more than enough for the purposes of these cases.

One instance of alleged prior use remains. Before 1879 Brayton undertook to furnish an engine which would drive an omnibus to certain men in Pittsburg. It is shown that he endeavored to adapt his then well known engine to traction purposes. That he failed utterly is clearly proved; the reasons for his failure are not so clear, but the failure is enough to invalidate the defense.

No litigation closely resembling these cases has been shown to the court, and no instance is known to me of an idea being buried in the Patent Office until the world caught up to and passed it, and then embodied in a patent only useful for tribute.

But patents are granted for inventions; the inventor may use his discovery, or he may not, but no one else can use it for seventeen years. That seventeen years begins whenever the United States so decrees by its patent grant. That the applicant for patent rights acquiesces in delay, or even desires delay, is immaterial to the courts so long as the statute law is not violated. On these principles complainants are entitled to a decree.

The Panhard machine does not in my judgment infringe the second claim. Construed as they have been in this opinion, infringement of claims one, two and five by the Ford machine, and of one and five by the Panhard can hardly be said to be denied. It is so found, and decrees will pass accordingly.

C. M. HOUGH,

September 8, 1909. U. S. D. J.

Spark Plug Patent Litigation.

A. R. Mosler & Co., of New York, have commenced a suit in the United States Circuit Court in New York against the Auto Supply Company for infringement of the well known Canfield United States patent No. 612,701, granted October 18, 1898, for spark plugs, and owned by them. This patent is claimed to broadly cover a spark plug provided with a deep chamber or recess around the electrode for the purpose of preventing an injurious accumulation of soot or other foul matter on the insulation of the electrode, which is a feature of many spark plugs now upon the market in this country. Messrs. Mosler recently acquired the Canfield patent from the Association Patents Holding Company, a subsidiary organization of the Association of Licensed Automobile Manufacturers.

The City Council of Pasadena, Cal., has so amended the automobile ordinance of the city as to permit the transfer of a license from one car to another, if the original car is sold.

## To Manufacture Motor Trucks in the Far West.

The Spokane Motor Car Company has been organized with a capitalization of \$600,000, and incorporated under the laws of Washington, to manufacture in Spokane an original type of commercial automobile. The incorporators are V. E. Funkhouser, Portland, Ore., president; Edward Schulmerich, Hillsboro, Ore., vice president; F. M. Skiff, Portland, secretary; A. L. MacLeod, Portland, treasurer, and Thomas Bilyeu, Portland, general manager, who, with F. H. Whitfield, of Portland, and W. P. Lafferty, of Corvallis, Ore., compose the directorate.

President Funkhouser announced in Spokane that work on a plant to give employment to 150 mechanics would begin in a short time. The product will be confined to heavy commercial cars, propelled by gasoline, with power applied directly to all four wheels. A fifth wheel construction enables the car of 171/2 feet length to turn within its own length.

The truck has no rear axles. The rear wheels are supported by two suspension axles, supported themselves by steel frames and blocks on each side. The axle of the front wheels "plays" up and down in a groove 6 inches long, enabling the truck to pass over obstructions from 6 to 24 inches high without noticeably disturbing the platform. The loading space is so arranged that the load will be distributed on all four wheels, instead of the entire load being carried on the rear wheels, in order to get sufficient traction. A four cylinder gasoline engine is used, generating 50 horse power. The company plans to manufacture the car in several different sizes, from 11/2 to 7 tons capacity.

#### To Build Cars in Oswego, N. Y.

The Pell Motor Car Company has been organized at Oswego, N. Y., with \$150,000 capital stock, to manufacture low priced automobiles. The directors for the first year are C. C. Place, A. N. Radcliffe, John P. Miller, D. W. Pell, E. D. Long, H. A. Wilcox and C. A. Bentley. The election of officers will take place at an early date. The company has secured quarters in the Ontario Industrial Building now in course of erection, and will begin work just as soon as the building is finished. A model car has already been built to order outside. The organization of this company was first announced in these columns about a month ago.

#### Short Measure Gasoline.

Rudolph Baumert, Indianapolis manager of the Standard Oil Company, was arrested by Isidor Wulfson, inspector of weights and measures in that city, for giving short measure in selling gasoline. W. B. Craig, an automobile owner, made the complaint, and investigation showed there were 4½ pints short in 20 gallons. Baumert was fined in police court, but has taken an appeal to a higher court.

#### **OUR FOREIGN EXCHANGES**

#### Benz & Cie.'s Annual Report.

The annual report of Benz & Cie., the well known German firm, for the business year which ended on April 30 last, is not at all satisfactory. A reason assigned for this fact in the report is that during the past year the entire business was transferred to the new, large and modernly equipped factory, and this removal had a retarding effect on the work for months, besides causing considerable difficulty in the acquisition of new skilled metal workers. Interruptions were also caused by the necessity for acquainting the workmen with the new machines. This made it impossible to materially increase the output, while, on the other hand, the expenses were considerably increased by the enlarged scale of operations. The report continues that during the current year the output has been constantly enlarged, and a favorable balance is to be expected. The gross earnings of the company for the past year amounted to 2,092,094 marks, as compared with 2,342,-341 marks the previous year. The sales expenses rose from 1,036,655 marks to 1,345,-The operating expenses 617 marks. amounted to 369,782 marks, as compared with 362,973 marks. After writing off 320,-367 marks, there remained a surplus of 56,-326 marks, which was carried forward. The company distributed a dividend of 15 per cent. in 1906-1907, and of 8 per cent. in 1907-1908, but for 1908-1909 the dividend was passed.

#### British Patents Act.

According to Consul Horace Lee Washington, of Liverpool, the result of the first year's working of the British patents act has been that \$2,500,000 of foreign capital has been introduced into the United Kingdom, as the following indicates:

The value of the land and premises acquired by foreign firms who have decided to carry on their manufactures in this country in order to maintain patent rights is estimated at \$635,000. The expenditure for buildings was \$880,000; plant and machinery, \$895,000, making a total of \$2,410,-000. The annual local assessments on these new enterprises is estimated at \$135,692. In addition it is stated that a great many firms have arranged for English factories to manufacture their patented articles on a royalty basis. A specialist in factory property stated in a recently published interview that his firm was in negotiation with several German and American firms for the acquisition of sites and factories, principally in the chemical, engineering, electrical and rubber making trades, and that a French firm of pottery makers are seeking a site for a model village. He estimated that twenty-four firms are already manufacturing there as a result of the act.

#### Royal A. C. Does Not Want Speedways.

The Royal A. C. of Great Britain and Ireland held a discussion of the Lloyd George Road Improvement Funds Bill on September 3, and unanimously adopted the following resolution:

"That the general committee of the Royal Automobile Club and associated clubs expresses its satisfaction with the Development and Road Improvement Funds Bill (Par II), and further expresses the lrope that the attention of the Road Board will be specially given to the improvement and

francs more French automobiles than during the first seven months of last year. The imports of foreign cars into France remain in almost negligible quantity, the aggregate value for the first seven months of the year being hardly 4,000,000 francs.

#### Brazilian Rubber Exports.

Consul George H. Pickerell, of Para, transmits the following statistics and comments on the shipment of rubber from that Brazilian district for the past three fiscal years ended June 30 (kilo = 2.2 pounds):

				Europe		
Quality.	1907. Kilos.	1908. Kilos.	1909. Kilos.	1907. Kilos.	1908. Kilos.	1909. Kilos.
Fine	8,785,388	7,086, <b>966</b>	8,730,908	9,894,955	11,158,327	9,616,696
Medium	2,024,044	1,501,987	1,752,602	1,597,343	1,890,246	1,732,844
Coarse	5,839,035	4,414,167	6,074,267	3,245,317	3,452,788	2,684,025
Gaucho	1,627,631	1,655,160	<b>2,</b> 504,856	4,653,064	5,263,165	5,138,673
Total	18.276,098	14,658,280	19,062,633	19,390,679	21,764,526	19,172,238

widening of existing roads for facilitating motor traffic, rather than to the construction of special motor roads.'

The Scottish A. C. executive and legal committees held a joint meeting on September I, and the discussion brought out the fact that the views of these committees are substantially identical with those of the Royal A. C.—that is, they hold that the construction of speedways should be deprecated, and the improvement of existing roads encouraged.

#### French Exports for Seven Months.

The French exports of automobiles for the first seven months of the current year show a material improvement over the corresponding figures for last year, and only a slight decline over the record year of 1907. The value of the exports during the first seven months of 1909 was 85,687,000 francs, as compared with 77,694,000 francs during the same period in 1908, and 89,865,-000 francs during the same period in 1907. The distribution of the exports among the different countries was as follows:

	rrancs.
United Kingdom	38,207,000
Belgium	10,363,000
Germany	6,072,000
United States	5,395,000
Argentine	4,369,000
Algiers	4,000,000
Russia	2.966,000
Spain	2,120,000
Switzerland	2,085,000
Italy	1.941,000
Brazil	722,000
Austria-Hungary	623,000
Turkey	385,000
Various countries	6,439,000

Five of the above named counties have reduced their imports of French automobiles in comparison with the previous years, particularly Germany, whose imports show a decline of 1,679,000 francs; Brazil, 630,000 francs; Turkey, 71,000 francs; United States, 53.000, and Spain, 14.000 francs. The imports of the other countries show an increase, especially those of Belgium, which imported for 3,600,000 cost of ordinary methods.

"Contrary to the anticipation of producers the rubber production of last year has been considerably greater than that of the previous equal period, and has almost reached the amount produced in 1907, the year of greatest production. Notwithstanding this unexpected large yield prices have shown an enormous tendency to rise, and it would seem from present reports that the end has not yet been reached; \$1.65 per pound f. o. b. New York is high when one considers that just a little more than one year ago the same article was selling in the same market for 63 cents. It is too soon to tender any opinion upon the coming season's crop, but I feel sure that every effort will be made to take advantage of the present high prices. The effect of all this good fortune will hardly be felt before 1910, but some in anticipation of another successful year have commenced to lay plans for increasing and improving their present production facilities."

#### Lion Motor Car Company Organized.

The Lion Motor Car Company, of Adrian, Mich., was formally organized at a meeting at the Griswold House at Detroit on September 15. The new company is capitalized at \$350,000. The plant is to be located at Adrian, that city having granted a bonus of \$15,000 for the factory. The officers are as follows: President, Henry C. Bowen, Adrian; vice president, Fred Postal; secretary, Leslie Robertson, Adrian; treasurer. William E. Morey; assistant treasurer, William Shierson. The company plans to produce 2,000 cars next year. Work on the remodeling of the building was ordered begun at once. It is generally understood that the manufacture of the machines will begin the later part of this year.

Successful experiments are under way, near Nottingham, England, with a Britishmade agricultural motor. It is claimed to do plowing and harvesting at one-sixth the

#### MINOR MENTION

The Phoenix Automobile Accessories Company, of St. Louis, Mo., have established a branch at Kansas City, in charge of Chas, Thayer.

The W. A. Patterson Company, of Flint. Mich., one of the largest carriage concerns in the West, has broken ground for a new factory building for manufacturing automobiles.

According to a report from Anderson, Ind., the Indiana Rubber and Insulated Wire Company is erecting a new building in Jonesboro, Ind., to experiment with automobile tires.

The Kissel Motor Car Company, of Hartford, Wis., has doubled its capital stock in order to provide for the growing business. The capitalization now is \$400,000. Several additions are being built at Hartford.

Mr. Greenlaw has purchased all of Mr. Wordingham's interest in the Wordingham Foot Horn Company, of Milwaukee, and the name of the company has been changed to the Wordingham Manufacturing Company.

The new factory building of the A. O. Smith Company in Milwaukee, Wis., is nearing completion. The main building, which measures 1.025x287 feet, and is of solid concrete, steel and brick construction, is now under roof.

Wm. B. and Milton O. Bard, of Johnstown, Pa., have secured a patent on a four wheel drive, and are at present constructing a machine embodying the invention. They are planning to organize a company to manufacture the machine.

In the recent Lowell stock chassis race the cars finishing first to fifth were all equipped with Michelin tires. In the race for the Vesper Club trophy the first five places also fell to cars equipped with Michelin tires, and in the contest for the Yorick trophy first and second places were secured by cars fitted with Michelins.

Horace De Lisser, president of the Ajax-Grieb Rubber Company, has offered a trophy to be known as the Ajax Cup for the Star Tour, which started September 20 at Kansas City, Mo. This cup will be awarded to the contestant in the runabout division in either the dealers' or owners' class who crosses the finish line with the best score.

The Embree-McLean Carriage Company, of St. Louis, Mo., have entered the automobile field, and plan to turn out about 500 cars the coming season in three models, as follows: A 30 horse power light roadster, with 105 inch wheel base; a 35 horse power light touring car, with 116 inch wheel base, and a 40 horse power seven passenger touring car, with 120 inch wheel base. All three cars will be equipped with four cylinder, four cycle motors and three speed

selective steering gears. The first cars will be ready November 1.

The Overland Automobile Company have let the contract for a new building for its Toledo, Ohio, plant, to be located on Central avenue.

It is reported that the receivership of the Kauffman Buggy Company, of Miamisburg. Ohio, will shortly be terminated, and that the factory will be sold to a company which plans to make automobiles.

The Nordyke & Marmon Company inform us that they have not issued a statement to the effect that they will not take part in track races in the future, as was reported in one of our recent issues.

The Great Western Motor Car Company, Peru, Ind., held its annual meeting on September 14, and elected the following directors: Milton Kraus, R. A. Edwards, E. A. Myers, Albert Kittner, R. H. Bouslog, W. S. Mercer and A. L. Modurtha.

An improved steel guide post for country crossroads, which can be produced at low cost, has been invented by B. H. Cooley, of Campbellsport, Wis., and will be manufactured there. It consists of a 2 inch cast iron pipe, with a special interchangeable cap.

The York Motor Car Company, of York, Pa., who have been represented in San Francisco by Frank O. Renstrom for a number of years past, have decided to open a factory branch in that city, and have sent C. B. Gardiner there to represent them.

In Youngstown, Ohio, there are said to be about 125 electric vehicles in operation, and the Electric Storage Battery Company, of Philadelphia, is planning to establish a branch there for assembling batteries and doing repair work. A site on Belmont avenue is being considered, and the branch may be opened within a month.

The Hartford (Conn.) Auto Parts Company at its recent annual meeting elected the following officers: W. H. Cadwell, president and treasurer; F. H. Bogart, vice president and manager; F. L. Martin, secretary. The company manufactures universal joints and other parts. The company has increased its capital stock from \$50,000 to \$100.000.

This year Richard G. Wagner, of Mil-waukee, Wis., president of a syndicate of beet sugar manufacturers, inspected the beet sugar crop from an automobile, and shortened his annual tour of beet sugar fields by one-half. The factories as well as the fields are widely separated throughout the State. Mr. Wagner was able to drive directly into the fields and inspect the crop without leaving the car.

E. T. Rogers and R. T. Overbolt, who are said to be connected with a well known Wisconsin automobile company, are endeavoring to interest Des Moines, Ia., capitalists in a proposition to locate a factory there for the manufacture of automobiles for farm use, ranging in price from \$500 to \$800. Messrs, Rogers and Overbolt went to Des Moines on the invitation of

the Commercial Club, and while there were entertained by the Greater Des Moines committee.

Leslie Elliott, of Pomona, Cal., has bought a building on West State street, and will establish a tire repair shop there.

The Sellers Motor Car Company, which began manufacturing automobiles in Hutchinson, Kan., last summer, is now said to be turning out three cars a week, and plans to produce 200 cars for next season.

Nine cars have been entered for the twenty-four hour race, to be held on the Brighton Beach "motordrome" on Friday and Saturday of this week, viz., two Loziers, Buicks and Rainiers each, and Fiat, Palmer-Singer and American Roadster.

A meeting was recently held at the office of Mayor Breitmeyer, of Detroit, to discuss a proposition to establish a permanent automobile exhibition in that city. It was attended by representatives of most of the leading manufacturers. No definite action seems to have been taken.

Space diagrams and application blanks have been issued for the tenth National Automobile Show, which is to be held at Madison Square Garden January 8-15. First allotments of space will be made October 7. M. L. Downs, 7 East Forty-second street, New York, is secretary of the show committee.

The St. Louis branch of the Fisk Rubber Company, of which A. N. Stanley is manager, will soon have a new two story building, with an office and a salesroom on the first floor, and a repair room on the second floor. The present quarters of the company, at 3907 and 3909 Olive street, have become inadequate.

The Charles Waugh Company, of Cambridge, Mass., an old established carriage manufacturing company, has entered the automobile business and secured the agency for the trucks made by the American Motor Truck Company for Boston and vicinity. The Waugh Company makes bodies for these trucks to suit the different requirements.

The Reo Motor Car Company, of Lansing, Mich., on September 15 presented all their employees who had been with the company for a year or more with a check for a sum equal to 5 per cent. of their wages for the year. The company made a similar present to their employees a year ago. This year the aggregate of the checks amounted to \$10,000, which is \$3,000 more than the amount last year.

Following the resignation of Alfred S. Koto, assistant manager of the Warner Instrument Company, of Beloit, Wis., it is announced that Mr. Koto, with Thomas Odee, will start a manufacturing plant at Beloit. It is said that the product will consist of automobile devices, parts and accessories. Mr. Odee has been superintendent of the gasoline engine department of the Fairbanks-Morse Manufacturing Company at Beloit for several years, and is an experienced designer and builder. The T.

A Johnson wagon works factory has been leased for the new plant.

#### Club Notes.

The new clubhouse of the Dixon (Cal.) A. C. was dedicated on September 17. The club owns its own garage, the use of which is free to members and their friends.

Motorists of Athens, Sayre and Waverly, Pa., organized a club at a meeting held on September 7, starting with a charter membership of sixty-two. The officers of equipped with tachometers, which is to be of of Athens, president; Frank A. Bell, of Waverly, vice president; J. T. Corbin, of Athens, secretary, and C. C. West, of Sayre, treasurer. A committee on constitution and bylaws was appointed.

## New Commercial Vehicle Concern in Minneapolis.

The Robinson-Loomis Motor Truck Company have been incorporated in Minneapolis, with \$50,000 capital stock, and have secured a plant at Second avenue North and Seventh street. The company will manufacture the Gopher truck, and handle the Reliance trucks and delivery wagons in the Northwest. T. F. Robinson, president and general superintendent, has been engaged in the commercial vehicle business for some years, having been manager of the only exclusively commercial garage in Minneapolis, while F. L. Loomis, secretary and treasurer, was formerly sales manager for the Reliance Motor Truck Company.

The Gopher truck, Model A, is a two cylinder, 22 horse power vehicle, while Model B is equipped with a 30 horse power motor. Both machines have force feed lubrication and a water cooling system. Engine speed is controlled by spark and throttle levers on the steering column. The cars are fitted with a selective type of change gear, giving three forward speeds and one reverse. The rear axles are of solid square section, 2x2 inches, while the front axles are of 2 inch I section. The car has a wheel base of 98 inches and a side chain drive to the rear wheels. The I ton model sells at \$1,800 and the 2 ton at \$2,200.

Overland Southern Company Organized.

The Overland Southern Company has been organized at Atlanta. Ga, and on Octoher 15 will occupy the Peachtree Auditorium as a garage. The building is at present being overhauled and remodeled. H. L. Hopkins, manager of the Atlantic Refining Company, is president of the Overland Southern Company. R. C. Smith, formerly of Lansing, Mich., who has been connected with the Reo interests, will be sales manager of the company, and John N. Willys and F. A. Barker, of the Overland Automobile Company, will be memhers of the advisory board of the Overland Southern Company. The territory of the new company will comprise North Carolina, South Carolina, part of Virginia, eastern Tennessee, Georgia, Florida, Alabama and the West Indies. The company plans to open a showroom on Peachtree street in the vicinity of the Auditorium.

## Rambler Factory to Drop Forge Its Own Crank Shafts.

Thomas B. Jeffery & Co. have just put in a giant forging hammer, for making all crank shafts, connecting rods, front axle yokes and other heavy forgings. It has a falling weight of 3,500 pounds, making it capable of striking a blow of approximately 15,700 pounds. The anvil block weighs 70,-000 pounds, and the total weight of the hammer is 98,000 pounds. This press has been set up on a foundation of solid concrete 16 feet deep and 15 feet square, with cushions consisting of oak timbers. In addition to this a 500 ton drawing press for the shaping of brake drums, clutch cones and other heavy drawn steel parts, has been installed. This press weighs 60,000

#### Overland Capital Increased.

Directors of the Overland Automobile Company held a meeting at the factory in Indianapolis on the afternoon of September 15, and voted to increase the capital stock from \$800,000 to \$1,500,000. It was also decided to change the name of the company to the Willys-Overland Company. The company states it will build 20,000 cars during the coming season, of which about 9,000 will be made in Indianapolis and 11,000 at Toledo, Ohio. Recently three large factory buildings have been completed in Indianapolis.

#### Ohio Agencies Consolidated.

By the incorporation of the Charles Schiear Motor Car Company, with a capital stock of \$25,000, the Southern Ohio Motor Car Company, of Columbus, and the Evanston Auto and Garage Company, of Cincinnati, have been merged into one corporation. The incorporators were Charles Schiear, C. Roy Clough and others. A branch will be operated at 3705 Main avenue, Cincinnati, and another at 61 East Spring street, Columbus. The principal part of the wholesale business will be conducted at the Columbus branch, of which C. Roy Clough will be manager. The corporation has about fifty counties in central and southern Ohio for the Hupmobile and Velie lines. Others will be added as soon as contracts are signed.

## Wheel Company to Make Motor Buggies.

The Whiteside Wheel Company at Indianapolis, which has devoted its attention to the manufacture of wheels, will bring out a high wheeled car for the season of 1910. It will be known as the Vaughn runabout, and will have 38 inch wheels, fitted with 2 inch solid tires. The engine will be of the two cylinder, 20 horse power. Beaver type, while the Vaughn friction transmission will be used.

## Transcontinental Dash Has Fatal Ending.

A car which started from Philadelphia at noon on Saturday on a transcontinental trip for the Philadelphia *Press*, carrying a messenger who was to deliver a message from President Taft to the president of the Alaska-Yukon Exposition at Seattle, was wrecked at 3 o'clock in the afternoon near Reading, Pa., and the courier, Henry L. Buckley, was mortally injured, and died later in the Reading Hospital. Other passengers of the car were more or less injured, and the trip was immediately called off. It appears that the car got beyond the control of the driver, and collided with a telegraph pole.

#### Lipman to Manufacture Cars.

Carl E. L. Lipman, of Beloit, Wis., who has been engaged in the manufacture of automobile parts, particularly circulation pumps and speed indicators, for many years, is at present constructing a six cylinder, 35 horse power car, to sell at \$1,500. The car has a very long wheel base and 34 inch wheels. Mr. Lipman is at present looking for a suitable location for a factory.

#### Business Trouble.

An involuntary petition in bankruptcy was filed September 9 in the United States District Court against the Kelsey Company, Inc., manufacturers and dealers in automobile and bicycle supplies, 45 Niagara street, Buffalo, N. Y., by Wm. E. Kelsey and others. Kelsey presented a claim for \$3,555.52 on a note, and other petitioners presented claims for amounts on open accounts. It is charged that the alleged bankrupt expressed its willingness to be adjudged a bankrupt, and admitted its inability to pay its debts.

Bids for Ohio Tags.

Bids for furnishing the Ohio State automobile department with 35,000 sets of tags for the year 1910 were opened by the Secretary of State September 15. Five bids were submitted, all of which were under the price for the present year, 50 cents a set. Samples of the tags will be furnished by each bidder, and these will be given a thorough physical and chemical test by Professor Edward Orton, of the ceramics department of the Ohio State University.

When translators not versed in technical matters are asked to make translations of letters, etc., containing technical terms exceedingly queer expressions are sometimes coined. The Marine Review reports a case where a Syrian interpreter in translating a letter in Arabic to a Manchester firm made use of the term "water sheep," which was finally made out to be an hydraulic ram. The Arabs, in adopting a name for this modern mechanical appliance, evidently followed the lead of the French, who call a ram a "mouton." An Italian translator of an article on gasoline motors spoke of the crank shaft as the elbow tree.

Garage Notes.

The Packard Motor Car Co. has recently opened a branch in Hartford, Conn., on Allyn street.

The Washington Boulevard Garage, 41-3 Washington Boulevard, Detroit, Mich., has been opened for business.

W. J. Courtney and W. N. Wesn, Newhampton, Ia., have purchased the Putney livery property, which they will remodel into a garage.

The Horton Motor Co., who have stores at Minneapolis, Minn., and Mayville, N. Dak., are building a garage in Devil's Lake, N. Dak.

Ramsthel Brothers, Grand Island, Neb., will shortly open a garage in the Donner Building, which has recently been purchased by H. L. Hayden,

A three story cement block garage building is to be erected on the Schriver property on North Perry street, Johnstown, N. Y. Work on the building may begin this fall.

The R. G. Dobbins estate, Philadelphia, are erecting a garage building at 253-9 North Broad street, at a cost of \$28,000. Work on the building was started September 15.

Guy Bailey has purchased the interest of his uncle, E. C. Bailey, in the Bailey Garage in Grundy, Ia. Young Mr. Bailey has been connected with the business for some time.

The Studebaker Automobile Sales Co., Columbus, Ohio, has leased a new building at North Fourth and Chestnut streets, in which it will conduct a garage and agency. A. J. Pray is general manager.

Mayor Wm. F. Brooks, of West Somerville, Mass., is erecting a 150x55 feet garage on the site of the historic Porter's Hotel on Massachusetts avenue, North Cambridge, which has been torn down.

Leece & Watterson, Bishop, Cal., have erected a corrugated iron garage in the rear of their store for their commercial vehicles. The building will also serve as a salesroom for gas engines and pumps.

F. B. Henderson, of New York city, will erect a garage on Cheyenne street, between Fifteenth and Sixteenth streets, Denver, Col. The building will cost \$25,000, and will have a warehouse and salesroom.

The Metropolitan Motor Car Co., Seattle, Wash., will erect a one story concrete garage building, 70x100 feet. Bruce A. Griggs is manager of the company, which has the agency for the Acme and Pullman cars.

L. B. Vollmer, Monrovia, Cal., has installed a charging plant in R. B. Cowan's garage on Lemon avenue, and will open as an electric garage on October 1. Mr. Vollmer handles the Detroit electric and the Columbus electric.

H. Schaffer, of Fullerton, Cal., is heading a company of Santa Paula, Cal., capitalists which has purchased the California Hardware and Tool Co.'s shops and will remodel the same into an automobile and oil tool repair shop.

E. W. Alfriend. Atlanta, Ga., is planning to erect a new building on Peachtree street, with a front of white enameled brick and plate glass, two or more stories in height, the first story of which will be used as an automobile salesroom.

Carl Jones and Louis Indra, Green Bay, Wis., have opened a garage on North Broadway under the style of the West Side Garage. Mr. Jones was formerly manager of the Kruger Garage at Oshkosh. The new company intends to handle several lines of cars.

The Empire Motor Car Co. has been organized in Syracuse, N. Y., and has secured headquarters at 244 West Genesce street. The company will handle Regal cars in eighteen counties of central New York, and are introducing them to the public by exhibiting at the New York State Fair this week. Geo. D. Wilcox is manager of the new company.

The Rambler Automobile Co., Cleveland, Ohio, has taken a lease of a new building to be erected on Sixty-fifth street and Euclid avenue. The building, which is to be completed by February 1, is to have ground dimensions of 60x100 feet. The front portion of the first floor, 60x60 feet, will be used as a showroom, and will have a polished

maple floor and frescoed walls. Geo. S. Patterson is manager of the company.

The Reading (Pa.) Automobile Co. have established a branch store in Pottsville, Pa., at 202 South Centre street, which premises they have leased for a number of years. The company handle Buick and Franklin cars. H. O. Koller, of the Reading Automobile Co., will manage the branch, which is to be known as the Pottsville Motor Car Co.

The Kenny Motor Car Co., which has just secured the agency for Rambler cars in Brooklyn, New York, and vicinity, has purchased a corner property at Sterling place and Bedford avenue, Brooklyn, where a modern building, including a garage and a storeroom, will be erected immediately. The members of the firm, Wm. F. and T. A. Kenny, are well known Brooklyn business men.

New Incorporations.

Fry & McGill Motor Supply Co., Denver, Col.— Capital stock, \$100,000. Incorporators, John E. Fry and James McGill.

Lloyd Automobile Co., Portland, Ore.—Capital stock, \$40,000. Incorporators, W. E. Cook, C. B. Lloyd and L. Templeton.

Western Garage, Marysville, Cal.—Capital stock, \$10,000. Incorporators, J. E. Coombs, W. G. Humphrey and H. B. P. Gardiner.

Evansville Taxicab Co., Evansville, Ind.—Capital stock, \$10,000. Incorporators, Gustav Zeidler, J. F. Charley and A. O. Harnishfeger.

Miller Motor Co., New York, N. Y.—Capital stock, \$30,000. Incorporators, Chas. Miller, Lawrence H. Cummings, Geo. W. Schaefer.

Dahl Punctureless Tire Co., Minneapolis, Minn.

—Capital stock, \$50,000. Incorporators, A. N.

Dahl, Benj, Dahl and F. H. Stevens.

The Taxicab Co., Cleveland, Ohio.—Capital stock, \$10,000. Incorporators, Moses R. Braily, F. E. Braily, C. B. Gaw and R. M. Gaw.

The Red Ball Automobile Co., Enid, Okla.— Capital stock, \$10,000. Incorporators, W. H. Hill, Geo. J. Emrick and Orie J. Wilkinson.

Wright-Rye Motor Co., Troy. N. Y.—Capital stock, \$40,000. Incorporators, Wm. D. K. Wright, Wm. H. Rye and George A. Hubbard.

Maxwell-Briscoe-Toledo Co., Jersey City, N. J.— Capital stock, \$2,000. Incorporators, S. A. Anderson, L. H. Gunther and H. O. Coughlan.

Anti-Friction Wheel Company, Pittsburg, Pa.—Capital stock, \$150,000. Incorporators, Thos. Bernston, Geo. D. Williams and Geo. L. Lothamer. Connersville Auto Supply Co., Connersville, Ind.—Capital stock, \$4,000. Incorporators, A. E. Goble, Alva Adams, Ray Thornburg and John Keucht.

Mosher Automobile Co., Anderson, Ind.—Capital stock, \$6,000. Incorporators, A. T. Mosher, J. E. Van Deventer, J. L. Vermillion and E. E. Young.

The St. Paul Motor Vehicle Co., St. Paul, Minn. —Capital stock, \$100,000. Incorporators, John Vieregge, Alma Vieregge, Felix Joswich and Jessie Joswich.

The National Automobile Co., Cincinnati, Ohio.—Capital stock, \$50,000. Incorporators, D. Linn, Abraham Tuttleman, E. M. Harris, J. L. Kohl and Edward E. Keeney.

The Acorn Motor Car Co., Cincinnati, Ohio.— Capital stock, \$20,000. Incorporators, Henry Louhier, Wm. C. Meyer, Emilie M. Maitre, B. F. Bryan, William Elwood.

The Ohio Electric Co., Toledo, O.—Capital stock, \$75,000. Incorporators, Henry P. Dodge, Rathbun Fuller, Henry E. Marvin, James Brown Bell and Robert R. Lee.

The Bergen and West Side Motor Car Co., Jersey City, N. J.—Capital stock, \$100,000. Incorporators, Chas. E. and Martha L. Collard, and Beverly D. Sparks. (To carry on a general garage business.)

The Euclid Automobile Co., Cleveland, Ohio.— Capital stock, \$25,000. Incorporators, John H. Watson, Jr., W. D. Turner, N. J. Webster, R. E. Robinson and J. C. Reforth.

The Toledo-Mitchell Co., Toledo, Ohio.—Capital stock, \$10,000. Incorporators, J. J. Vollmayer, Fredk. C. Schaal, Samuel McIntyre, William A.

Cavanaugh, William C. Vollmayer and W. H. McIntyre.

Petrie Auto Co., St. Louis, Mo.—Capital stock, \$10,000. Incorporators, C. G. Petrie, T. D. Petrie, F. M. Curlee, Roy Britton and A. D. Brown.

East St. Louis Automobile Co., East St. Louis, III.—Capital stock, \$2,500. Incorporators, M. L. Harris, Carl C. Housmann and J. R. McMurdo. Victoria Motor Car Co. Minneapolis, Minn.—

Victoria Motor Car Co., Minneapolis, Minn.— Capital stock, \$50,000. Incorporators, C. H. Robinson, A. W. Armatage, R. H. Rose, J. W. Hohman.

St. Paul Motor Vehicle Co., St. Paul, Minn.— Capital stock, \$100,000. Incorporators, J. A. Vieregge, Alma Vieregge, Felix Joswich and Jessie Joswich.

Ideal Auto Starter Co., Indianapolis, Ind.—Capital stock, \$25,000. Incorporators, W. K. Bellis, R. T. Snapp, S. A. Woodard, N. D. Woodarl and R. L. Smith.

The Franklin Motor Car Co., Columbus, Ohio,—Capital stock, \$10,000. Incorporators, F. H. Lawell, R. M. Todd, G. S. Ferguson, M. L. Welch and H. L. Clevenger.

Indiana Auto Parts Co., Marion, Ind.—Capital stock, \$75,000. Incorporators, G. R. Stewart. Richard Ruddell, H. D. Reasoner, F. C. Stephenson and J. D. Kennedy.

#### Trade Personals.

E. R. Lausier has been appointed assistant manager of sales of the Timken Detroit Axle Co., Detroit, Mich., and the Timken Rouer Bearing Co., Canton, Ohio.

W. F. Reynolds, who has been Texas representative for the Franklin Manufacturing Company, has been made manager of their new branch house at Pittsburg.

J. S. Draper, sales manager of the Mora Motor Car Co., of Newark, N. Y., is at present in Atlanta, Ga., with the object of establishing an agency for Mora cars there.

Carl A. Broesel, sales manager of the Simplex Automobile Co., of New York, was in St. Louis last week, with the object of establishing an agency for the Simplex car there.

R. G. Stanton, formerly with the H. O. Harrison Co., of Los Angeles, Cal., has been appointed sales manager of the Oldsmobile branch of the Woolwine Motor Car Co., of the same city.

The Pope Manufacturing Co., of Hartford, Conn., inform us that their engineer, L. B. Hubbell, has not resigned, as was stated in our last week's issue. The report originally appeared in a Wilkes-Barre paper.

H. J. Snider, who recently entered the employ

H. J. Snider, who recently entered the employ of the H. H. Franklin Manufacturing Co. as assistant to one of their office department managers, has been appointed manager of the Albany branch of the Franklin Automobile Co.

C. B. Warren, Pacific Coast representative of the F. B. Stearns Co., Cleveland, Ohio, has resigned his post to enter business for himself in St. Paul, Minn. He will be associated with Burney Bird in handling the Maxwell and several other cars.

Claude E. Cox has resigned his position as engineer and assistant manager of the Interstate Automobile Co., of Anderson, Ind., and has assumed a similar position with the Wilcox Motor Car Co., of Minneapolis.

At a meeting of the board of directors of the Oakland Motor Car Co., Pontiac, Mich., held on September 14, to elect a successor to the late E. M. Murphy, former general manager, L. L. Dunlap, factory manager of the plant, was appointed.

#### New Agencies.

Atlanta, Ga.—A. J. Haas, Winton.
San José, Cal.—W. T. Warren, Renault.
Philadelphia, Pa.—Frink & Co., Kline Kar.
Hartford, Conn.—Brown, Thomson & Co., Loier.

Philadelphia, Pa.- Longstreet Motor Car Co.,

Waltham, Mass.—Waltham Automobile Co., Winton Six, Stevens-Duryea, Overland, Marion, Stoddard-Dayton, Winton Model K, Regal and Speedwell.

NEW YORK, SEPTEMBER 29, 1909

NUMBER 13

#### The Second Annual Good Roads Convention.

CLEVELAND, Ohio, September 23.—The farmer and the automobilist joined hands at the second national good roads convention held in Cleveland September 21-23. The public highways are the primary means of transportation, all delegates to the convention agreed. Before the railroads there were highways. Since the building of the railroads there have been highways, although until very recently the city resident has appeared ignorant of the fact.

The railroads worked the first great change in the highways of the country—a change for the worse, according to George S. Ladd, special good roads lecturer of the National Grange, who addressed the convention Tuesday morning. The city resident almost forgot that there was such a thing as a country road; while the farmer, left alone to struggle with mud and dust, hole and rut, accepted bad roads as a necessary evil.

Then at length came the automobile, and the second great change in the highways of the country is being worked—a change for the better. The automobile, according to National Grange Lecturer Ladd, at first considered in rural communities as an intruder and a nuisance, is now credited by the thinking class of farmers as the source of the good roads movement. The farmer and the city man again are able to meet upon a common ground. Good roads are as much demanded by the one as the other. On the one hand the vision of the farmer has been broadened. He realizes today, as never before, the advantages of community life, the benefits of organization, of communication with his brother farmers and with the outside world, the need of centralized schools for his children, the advantage of easy access to his market. All these things he knows depend upon good

On the other hand the city resident, the manufacturer, the professional man, the merchant, is turning to the hills and the plains for his recreation and pleasure and for his health. He is finding a summer home next door to the farmhouse. And he, too, desires good roads. "Just how great a part the automobile has played in this united effort of the farmer and the city resident in behalf of good roads it is difficult to state," said National Grange Lecturer Ladd. "We can only say that until the day of the automobile the city resident was not concerned about country roads. He had turned the whole problem over to the farmer and then forgot that it existed. And

the farmer, before the automobile went spinning through his farm, didn't realize how far he was from his neighbors, how isolated was his life."

#### DOMINANT INFLUENCES.

The two dominant influences in the second national good roads convention were the American Automobile Association, representing the autoists and the cities, and the National Grange, representing the farmers. Co-operating with these organizations were the American Road Makers' Association, the National Association of Automobile Manufacturers, the Association of Licensed Automobile Manufacturers and the American Motor Car Manufacturers' Association. The Federal Government was represented by Logan W. Page, director of the United States Public Roads Office; while officially accredited delegates from forty-two States were in attendance.

"What we hope to accomplish by this national good roads convention," said Lewis R. Speare, of Boston, president of the American Automobile Association, before introducing George C. Diehl, of Buffalo, as chairman of the convention, "is the cooperation of State and Federal governments, of automobilists and automobile manufacturer, of farmer and city resident, that, working together, we may effect the improvement of our highways, the construction of new and the maintenance of

old, along some broad general plan calculated to bring the greatest good to the greatest number."

#### STATE AID AND CONTROL.

The sentiment of the convention was well defined in favor of centralized control by the various States of all highways within their borders and of the policy of annual appropriation known as "State aid" pursued by a majority of the Eastern States. National aid played but little part in the discussions. It was agreed that until the States were thoroughly aroused national aid in the good roads movement was beyond hope.

The three days of the convention were devoted to the reading and discussion of a series of papers, the list of speakers including the foremost men in the fight for better roads-men of the authority of Logan W. Page, of the United States Public Roads Office; ex-Governor N. J. Bachelder, of New Hampshire, Master of the National Grange; J. H. McDonald, State Highway Commissioner of Cennecticut; James C. Wonders, State Highway Commissioner of Ohio; S. Percy Hooker, State Highway Commissioner of New York; George S. Ladd, special good roads lecturer of the National Grange; T. C. Laylin, master of the Ohio State Grange, and F. N. Godfrey, master of the New York State Grange.

#### POINTS OF POLICY.

Direct State control of the construction and maintenance of all public highways, the

SPREADING THE CRUSHED STONE FILLER—THE TOP COURSE.

creation of the office of State highway commissioner in every State in the Union, the expenditure by this commissioner of all State aid road funds, the adoption by each State of a definite policy of trunk line roads, greater co-operation between the States, a reduction of the cost of road work so as to make improvement appeal to the farmer -these were the features, with but few exceptions, of all addresses and discussions. The futility of State appropriations to be used by local county officials in road improvement was generally conceded. This plan has been abandoned in most of the Eastern States, and it is there, the speakers asserted, that the good roads movement has reached its highest efficiency and greatest accomplishment.

The local system still prevails in Ohio, but was freely censured by the Ohio commissioner. James C. Wonders. "Ohio should not continue building State aid roadsin the indiscriminate manner pursued under the present law," said Commissioner Wonders. "Main market highways should be so selected that the roads of one county would connect with those of another, giving continuous highways that connect all important towns of the State. Furthermore, most of the State money now appropriated for new roads is spent by the counties in maintenance of the old. Though the counties are supposed to maintain existing roads at their own expense, almost without exception they have used the State aid funds for this purpose. I hope to secure at the next session of the Legislature the passage of a law making it illegal for the counties to expend State aid funds in any other work than the construction of new roads. In this way only will the mileage of the highways of Ohio ever be increased."

MILEAGE AND COST OF ROADS.

The most comprehensive address of the

convention was that delivered by Logan W. Page, of the United States Public Office of Roads, "In mileage we have the most tremendous system of roads which any country has ever possessed since the world began," said Mr. Page. "According to a careful road census, the length of all of our roads amounts to 2,155,000 miles. The most liberal estimate of our annual expenditure for these roads, both in money and in labor, was a fraction over \$70,000,000 in 1904. or about \$1.05 per capita. According to our road census, we have less than 40,000 miles of stone surface road, or about 2 per cent. of the total mileage. We have 108,000 miles of gravel road, or about 5 per cent. of the total mileage. Small as our annual expenditure for roads has been, it has aggregated, during the thirty year period from 1870 to 1900, a total of upward of \$1,800,000,000. We may, therefore, say that road building in the United States is, area, population and wealth considered, at the same point at which it stood thirty years ago, and the \$1,800,000,000 expended have produced few appreciable results."

Mr. Page then dwelt upon the necessity for good roads. "We need and must have more money for roads, definite provision for maintenance, a system of continuous repair and a centralized supervision," he said. "When we turn to the subject of road administration in the United States," Mr. Page continued, "we find that about half of the States are operating under practically the same road laws as prevailed in England when America was a colony. This system of road administration provides for the payment of road taxes partly in labor, and localizes the work to an extreme degree by placing in authority the district or township overseers, no requirement being made to secure skill or knowledge of road building on the part of these petty officials. This is

the system which prevailed in all the States until less than twenty years ago. It is, therefore, easily understood why at the present time the concrete results in the matter of road building are so few, are confined to a comparatively recent period and are found in those States which have broken away from the inadequate and ineffective system which I have just described.

ROAD ADMINISTRATION,

"Road administration has either been placed on a sound and practical basis, or steps have been taken in that direction in about half of the States of the Union, comprising the New England States, New York, Pennsylvania, New Jersey, Delaware, Maryland, Virginia, West Virginia, Ohio, Michigan, Illinois, Wisconsin, Minnesota, Missouri, Kansas, California and Washington. These States have adopted in principle or practice, or both, the system of centralizing under a State highway department the conduct of all or part of the road work of the State, thereby securing uniformity in methods, economy in administration and skill in supervision,

"In some of the States' highway departments the work is educational and investigative, with a view of ultimately giving these departments administrative powers. Some of the States, notably Kansas, Missouri and West Virginia, have provided for skilled supervision in the counties through the appointment of county highway engineers. In most of the States appropriations have been made from the State treasuries, or the aid of the State convict force has been given toward carrying on road work throughout the various counties.

"Be it said that the principle of State aid and supervision constitutes the germ of the only road administration which has proved successful. This movement is gaining headway at a very rapid rate, and, when we consider that it has been little more than a decade and a half since its inception, the fact that half of the States have adopted it in principle and have actually expended from State treasuries considerably over \$56,000,000, we may feel encouraged for the future of road building in this country."

EUROPEAN ADMINISTRATION SYSTEMS.

Mr. Page then outlined the various systems of road administration employed in the countries of Europe.

"In France we find the administration of roads highly centralized," said Mr. Page. "There are in France at the present time 23,656 miles of national routes, which cost \$303.975,000 to build. There are 310,898 miles of local highway built at a cost of \$308,800,000, of which sum the State furnished \$81,060,000 and the interested localities \$227,740,000." Speaking of England. Mr. Page said: "There are 149,759 miles of road in England, for which the annual expenditure for the year 1905-1906 amount ed to \$78,059,000. It is, therefore, apparent that the annual expenditure per mile amounts to about \$520. In view of the fact that most of the principal roads of Eng-

APPLYING ONE OF THE PATENT DRESSINGS. CARBO VIO.

land have already been constructed, this large annual expenditure would appear to be devoted in a large measure to maintenance. It would seem that a system which requires an annual outlay of \$520 per mile for the entire mileage must be ineffective and costly. The explanation of this is found perhaps in the fact that in England the maintenance of the public highways devolves entirely on the local authorities, these numbering about 1,000. The English system lacks strong central control, there being four different units of Government control-the county boroughs, the urban districts, the rural districts and the rural parishes.

"In Germany we find a federation of states," Mr. Page continued. "It follows that road administration is conducted separetly by each state of the Empire. The Imperial Government exercises very little control over the highways, and does not in any way contribute to the expense of their construction and maintenance.'

#### FAVORS CENTRALIZED STATE CONTROL.

From his study of the road systems of Europe Mr. Page draws an unqualified conclusion in favor of centralized State control. "England is the most striking example of extreme localization," he said. "And it is a significant fact that England is also the most striking example of lack of uniformity in road work and of excessive expenditure in proportion to mileage. It is also a significant fact that the most perfect road system, conceded to be such by all authorities on highway construction, is that of France, admittedly the most highly centralized of all the road systems. France, with a total mileage of about two and one-third times that of England, expends about the same amount annually for maintenance. Certainly the inference must be plain that centralization makes for economy and efficiency in the administration of the public

#### COSTLY MAINTENANCE.

"Road maintenance is the most important good roads question engaging the attention of American road builders and legislators," Mr. Page declared. "In the years that have passed," he said, "by far the largest portion of our annual expenditures has been made for maintenance, a maintenance which may be justly considered a mockery, for it has been a maintenance of the roads in almost their primitive condition. Now that we are actually building roads which compare favorably with the best of Europe, it is of the gravest importance that we make provision for safeguarding and maintaining these roads built at so great an expense.

"In a careful study of the highway laws which have been enacted within the past fifteen years I find almost no provision for the maintenance of the roads, although large sums are authorized for construction. The erroneous impression generally prevails that when a so called permanent road is constructed it is built for all time, and the expense has practically all been met. I have

A SECTION OF THE FINISHED ROAD. DARK LINE IS DIVIDING LINE BETWEEN TWO SECTIONS.

investigated the cost of maintaining roads in the leading countries of Europe, and the figures may almost be said to be a revelation. These express most forcibly two facts -that even the best of improved highways are not self maintaining, and that the cost of maintenance varies tremendously with the degree of centralization of the administrative organization which has the roads in

"Many of our States have spent and are spending large sums of money on their highways with but little thought or provision for maintenance. This, if the experience of European countries is of any value. must prove disastrous in two ways: First, granting that the roads constructed at so great a cost will not be allowed to go entirely to ruin, the cost of maintenance will be higher the more local and loosely centralized the organization for maintenance; second, systems of intermittent maintenance are sure to increase in cost from year to year as they have in Europe.

"It is high time that our legislators take note of these facts and provide ways and means so that our roads, once constructed, can be maintained efficiently and economically, and that exorbitant sums need not be expended on fruitless efforts to maintain them unsystematically and in an unscientific manner."

NEW YORK STATE COMMISSIONER'S VIEWS.

Although Mr. Page's address was generally approved, it met with opposition from at least one delegate, S. Percy Hooker, chairman of the State Highway Commission of New York. "It is a fallacy that all highways should be built directly by the State," said Commissioner Hooker. "This idea in New York State, at least, is not borne out by the facts. There the best of results have been obtained with the roads built and maintained by local officials, backed by State advice and funds." Commissioner Hooker also opposed the trunk line plan, contending that in New York better results have been secured by connecting populous centres without specific intention to complete a through State trunk line.

#### IMPORTANCE TO FARMERS.

To convince the farmer that the good roads movement was not entirely in the interest of the automobile owner was unanimously declared to be a pre-eminent necessitv.

James H. McDonald, State Highway Commissioner of Connecticut, voiced the sentiment of the convention when he declared that the roads of this country are its greatest public service corporation. The farmer here and there is blind to this fact, though to him it is most vital.

"The farm and city alike, the people of this country in general, do not appreciate the importance of this great question of good roads," said Commissioner McDonald. "The railroads have not settled the question of transportation. The farmer is still back there in the rural community, far removed from any railroad. The solution of the highway question lies in State aid and State supervision. But I would impress on this convention and upon this country that State aid and State supervision is not a political hatrack. It is not an eleemosynary institution. It is not a ladder to allow any man to climb to the height of his ambition. It is not an emergency hospital for the financially crippled. It is simply and solely a means to secure uninterrupted highways throughout the State and the Union. It must be so presented to the farmer, to whom in the last analysis we must turn for the furtherance of the good reads movement."

#### ATTITUDE OF OHIO GRANGE.

Speaking for the Ohio Grange, T. C. Laylin, master, said: "While we of the Grange may at times have differed with our city friends as to the best methods of raising

A SECTION OF THE ROAD BEING ROLLED

and expending the good roads fund, there has been no question of our attitude favoring the rapid improvement of the entire road mileage of this State. Unfortunately, however, there are thousands of farmers not allied with our organization. There is still urgent need of missionary work in rural communities on behalf of better highways.

"Good roads mean much to the farmer's comfort. He should be made to understand the variety of benefits which will flow from highway improvement. Good roads will result in centralized and better schools for the farmer's children, in an advantageous social and business organization of his community, in better communication of farmer with farmer and with the outside world, and, ultimately, I believe, in that greatest need of the farmers-the parcels post. These are the things pointed out some time ago by Theodore Roosevelt as necessary if the farmer is to remain on the farm. While there is no immediate danger of the failure of this country's food supply, there is such future danger unless the tide in the direction of the city is turned. Unless farm life can be made attractive America one of these days will be forced to import much of its food supply."

#### CONNECTING THUNK LINES.

George S. Ladd, National Grange lecturer, speaking upon the New England plan for connecting lines of trunk highways, said: "The New England plan of State co-operation in obtaining a system of connecting trunk lines of improved highways was evolved in a convention of State officials representing the six States. The plan determined upon has been faithfully followed. The result is speedily becoming apparent in a connected trunk line system unapproached anywhere else on the continent. Today we have available \$4,000,000 for the further prosecution of this work."

A feature of the convention was an exhibition of road building machinery and materials.

#### RESOLUTIONS ADOPTED.

Following the adoption of resolutions, in which the representatives of the National Grange, the American Automobile Association and the American Road Makers' Association pledged themselves in behalf of their respective organizations to enlist the cooperation of each of their constituent and affiliated bodies in highway improvement both by Federal and State aid, the convention adjourned Thursday noon to meet in 1910 in St. Louis.

"The convention has proved a complete success, especially from the educational standpoint," said President Lewis R. Speare, of the American Automobile Association. "Never in the history of the country has the subject of public highways received a more expert and scholarly treatment. The attendance also has been gratifying. The registration of delegates was 50 per cent. higher than last year in Buffalo."

The joy rider was given a rap at the last moment, when the convention resolved to request the aid of all law abiding automobilists in the enforcement of just speed regulations and in the apprehension of "the comparatively few offenders who are deaf to persuasion and persistent in disregarding the rights of their fellow occupants of the road."

Township, county and State officials, where empowered, were called upon to see that all roads are properly marked, and, where such authority does not exist, were urged to obtain the necessary legislation. The convention placed itself on record as favoring the Currier good roads bill, now pending in Congress.

#### NATIONAL COMMITTEE,

Following is the national committee, as named Thursday, to be in charge of the convention next year at St. Louis; George C. Diehl, Buffalo, chairman of the good roads board of the American Automobile Association; N. J. Bachelder, Concord, N.

H., master of the National Grange; James H. McDonald, Hartford, Conn., president of the American Road Makers' Association: Logan W. Page, Washington, D. C., directof the United States Office of Public Roads; C. F. Clarkson, of the Association of Licensed Automobile Manufacturers; S. D. Waldon, Detroit, president of the National Association of Automobile Manufacturers: Alfred Reeves, New York, general manager of the American Motor Car Manufacturers' Association; R. W. Smith, president of the Colorado State Automobile Association; S. D. Capan, president of the St. Louis Automobile Association; Louis R. Speare, Boston, president of the American Automobile Association; J. T. Drought, Milwaukee, secretary of the Wisconsin State Automobile Association, and F. H. Elliott, New York, secretary of the American Automobile Association

The accompanying photographs were taken on the experimental road near Columbus, Ohio, which was the subject of an article in our issue of September 15.

#### After the Cars Are Sold. By F. E. WATTS.

After a car passes from the hands of the agent to the user the factory's interest in it should by no means cease, for it has entered upon the work to prepare for which all the care in manufacturing and testing was expended. It is busily making a reputation for the company, and the company's interests demand that they know whether that reputation is good or bad.

Two departments are especially interested in the performance of the cars in the hands of their users, viz., the sales department and the designing department. The sales department needs to know just how far the cars are "making good," so that they may perfect the details for the next season's campaign. The designing department should keep in close touch with the cars so that faults may be remedied in future models, and so that each detail of the performance will be available as the basis of future designs.

As the men employed in these two departments are likely to change, this information should be recorded in such form as to be readily available to newcomers. Comparatively few companies have developed any systematic method of doing this, but I believe that the few who have considered the work almost indispensable.

Three sources of information at once present themselves when this subject is considered, namely, agents, users and the records of repair parts furnished. The first and the last are most commonly taken advantage of, while the users' troubles are ordinarily taken up in an unsystematic manner as they are told in a more or less coherent fashion by letters. Some manufacturers employ a force of "trouble men" whom they keep on the road most of the time, looking into faults and alleged faults making minor adjustments, keeping the cars

in tune, and the owners in good humor, all of which adds greatly to the reputation of the car they represent. In other factories this work is done in a half hearted manner, and only when an especially aggravating case makes it imperative. If a company has trouble men on the road it is comparatively easy to get detailed reports from a good many owners. Otherwise this must be done largely by mail.

Many companies do not take the trouble to get lists of the owners of their cars, but there are other makers who find it profitable to have their agents furnish them such lists at stated intervals. They can then use these lists when sending out information regarding new models, improvements applicable to old models, and new accessories.

Information regarding the performance of cars may be obtained by sending blanks to agents or users at regular periods. Such blanks may have headings somewhat as follows:

INFORMATION REGARDING THE CONDITION OF .....

Model..... Number.....

(Please record any breakage, looseness or other indications of undue wear in any of the following parts. Give details in full. Mention parts by serial number if you have repair list.)

Engine.

Radiator.

Clutch.

Change Gear,

Universal Joints and Driving Shaft.

Rear Axle.

Front Axle.

Springs.

Frame.

Bod▼.

Steering.

Brakes.

Control.

Wheels.

Tires (mention make).

General. (Under this heading note undue noise, appearance and ease of riding, and power as compared with when new.)

If the records of the repair stockroom are properly kept they form an invaluable list of the length of service a part gives. In some factories a copy of every repair part furnished is sent to the engineering department. These slips are classified so as to form a complete record of the percentage of repairs furnished on every piece. When a certain percentage of replacements is exceeded the part which is giving trouble is carefully examined for faults in design, manufacture or material.

These repair stockroom reports alone form an excellent basis for a system for keeping track of the performance of cars. When they are taken in conjunction with outside reports as detailed information as is required may usually be obtained.

Of course the method must be adjusted to the number of cars produced, and the price obtained per car. Obviously much less attention can be paid to the performance of each car by a company making 10,000 cars a year, and selling them for \$700 each, than by a company with an annual output of 100 cars, which retail at \$5,000 each.

#### That Costly Back Counter Boring. By G. E. P.

There is probably no more costly machine operation than back counter boring, which is a very slow operation and eats up time. A man may be making good time on a piece of work, but if the work requires a back counter boring operation, his effort does not show so well after it.

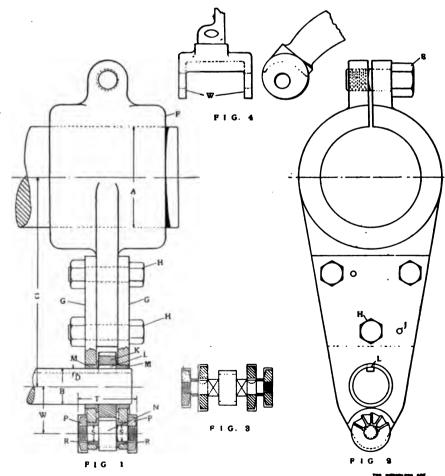

A sketch is herewith shown of a tool which I have used with great success, and, although it may not be entirely new to some of the readers of this paper, it will, no doubt, help a great many out of trouble. I have used this tool for straddle milling, as shown by the sketch, Fig. 3.

Fig. 1 shows the tool above mentioned, and a little explanation ought to make its construction clear. This tool was designed to be used on a plain milling ma-

chine with overhanging arm, the fixture being fitted to the arms at A and also at B, the arbor B fitting the spindle.

We have the usual spline D in B which when we loosen the hexagonal head cap screw E, Fig. 2, can be adjusted to suit the work. The body of the fixture F is made from a machine steel forging. Two plates of tool steel are fastened to F by the hexagonal head cap screw H and dowel pins J (Figs. I and 2), after the other parts have been assembled. The gear K is made of machine steel and is driven from B by a key L. Tool steel bushings are forced into the plates Q and are hardened and ground to a nice running fit on B.

Gear N meshes with gear K and the hub integral with N on either side is threaded to receive the cutters P. One thread is left hand and one is right hand. The part N is made of machine steel. The bushings R are of tool steel and are hardened and ground to fit N at S. The milling cutters P are made of a good grade of tool steel, and, of course, the diameter and the width T are made to suit the work. You are limited to the diameter of the cutters by whatever you make B and W. This fixture is very inexpensive when the amount of time it saves is considered. Fig. 4 is a sketch of one of the pieces for which this fixture was designed. The pieces alone paid for the fixture.

Tool for Milling Spring Horns, Etc.

## The Effect of Spark Timing on Engine Power as Shown by the Manograph.

By W. A. STILES.

It is a fact not generally recognized that nine out of ten cars are driven at all times with a decidedly low spark. This is due partly to the fact that it is difficult to tell just when the spark is timed exactly right, and partly because the speed of the engine is constantly changing, and drivers find that much less attention is required when the mixture is exploded late enough at moderately high speeds, so that no change is necessary should the engine slow up a little at times. It is often the case, too, that after two or three years' service the mechanism or couplings which drive an ignition system become badly worn, and the "backlash" represents the exact amount that the spark has been retarded; but the driver, having become used to setting the spark lever at a certain place, continues this practice without realizing that the engine should really be retimed. Often we will find a magneto being driven through a coupling, an oil pump, then another coupling and a set of gears, and the aggregate wear of all these parts in two years' service is surprising, although not when one considers that approximately one-tenth to one-fifteenth of a horse power is being driven constantly through this train.

#### EVILS OF LATE SPARK.

The evils of a late spark, or some of them at least, are well understood by the majority of car owners. Cracked cylinders, warped valves and boiled out radiators are all the direct result of the terrific blast of flame which tears out of the exhaust when the firing is retarded for too long a time. In fact, an air cooled car will not perform its duties unless the spark is advanced almost to the limit. But there is one other result which, although recognized, is not understood so well as these others, namely, loss of engine power. A dynamometer test will, of course, make any change of timing apparent at once, but the manograph will make it so obvious that one will at once realize the recessity of a spark which is timed just .ight.

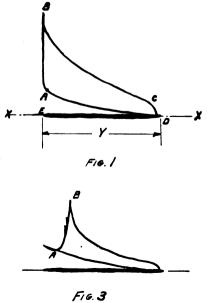

To follow this discussion further it is necessary that the use of the manograph card be understood, together with an appreciation of the meaning of the various curves and lines shown on it. Without going into a description of how the car is produced, then, we will consider the card shown in Fig. 1. In this figure the point A represents the point of explosion, B the peak of pressure which is instantly reached on explosion, B to C the line of work or expansion, C being the point of exhaust valve opening, D to E being the expulsion stroke. and from E back to D on the lower line the suction stroke. X-X represents the atmospheric line, and the dimension Y is the length of the stroke. The area enclosed by the compression, explosion and work lines represent power, and as a matter of fact a

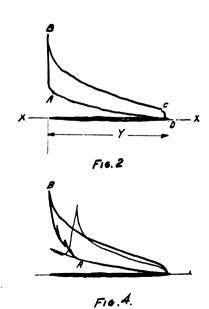

millimeter constant could be taken and the horse power developed at different times be figured. From this area, however, the area enclosed by the loop of the expulsion and suction strokes must be subtracted, as this latter is a dead loss. It will be noted that the spark is timed exactly right, for while it occurs a trifle before centre, yet by the time that the piston reaches dead high centre the combustion is just fairly under way. (This card was taken at 1,225 r. p. m.) A very high peak is obtained, and consequently a very large card area is shown, indicating a good power output. The compression curve is normal and does not show any overheating of gas, and the exhaust is chopped off fairly sharp and smoothly, this being a matter of exhaust valve setting.

In Fig. 2 we have another excellent card. which was taken under light load, and consequently the engine had less gas fed to it. It will be noticed that the explosion peak is much lower, and the expansion curve follows to some extent the curve formed by the compression and explosion, thus giving a thin card, showing that the engine is doing very little work. Fig. 3 shows us the beginning of a spark which is retarded quite decidedly. The compression line is brought up very normally to the high centre, but as the mixture is not exploded the curve travels back again almost in the same line. If the engine is new, with tight rings and running at a fairly high rate of speed, the return curve will either be exactly on the same path as it traveled coming forward, or a little above, due to the gas heating during the stroke. If, however, the engine speed be slow, and the rings or valves leaky, the back curve will drop somewhat below the forward one. It will be noticed that the line of combustion, when it does start, does not travel upward in a straight line, but is carried forward by the travel of

the piston. It indicates poor combustion. and the peak, besides not rising high, occurs too near the exhaust. This is an indication that trouble is at hand for the engine, and in Fig. 4 we see the results. of a spark carried late for too long a time. The firing point in this figure, instead of being considerably after centre, occurs when the piston is from one to two inches from top centre. The combustion line travels from the firing point in a ragged, broken line forward, as the piston has not yet finished its up stroke. The peak is low. due probably to leakage in the engine. The light line shown on the same card is the normal late firing line, which is imprinted on the manograph plate whenever the mixture does not explode prematurely. Often the engine will run on its late spark for fifteen minutes or so, and will then fire prematurely in quite regular fashion for a while, when it will shift back to the spark again. The premature firing is just about as hard on the engine as the late firing, as it knocks the bearings to pieces, strains the motor, and is apt to split a cylinder should the latter be at all weak.

There is one improvement the development of which has been badly neglected. I refer to the automatic spark governing advance. We have had automatic throttling governors of all sorts, but a governor which would be sufficiently sensitive to advance and retard the spark in exact proportion to the speed of the engine, and which would have the additional merits of being cheap and compact, would undoubtedly demand attention at the hands of the best motor designers of the country. Its first cost would be more than offset by the fact that there would be no advance lever, lever rod, universals or knuckle joints, and the fact that no hand manipulation is required would be a good selling point for a car, as well as a source of delight to its owner. It would certainly solve the problem of late timing, and eliminate many of its unpleasant results, and would probably increase the power of many motors.

#### Road Building Experiments.

Road building is an old art, and may be considered to have practically reached finality when only roads suitable for ordinary horse traffic are considered, but it is a well known fact that the best macadam and Telford roads leave much to be desired from the standpoint of automobile traffic. Such roads when subjected to considerable heavy and fast automobile traffic deteriorate rapidly, and in dry weather so much dust is raised on them by fast automobiles that both road users and residents along the roads are greatly annoyed. It has already become generally recognized that automobile traffic requires special road construction. In this country we have as yet comparatively few improved highways, and it is therefore possible, as our road system is developed, to adapt the roads to the automobile, and it is not imperative that the automobile should be adapted to the roads, as is practically the case where a complete network of improved roads already exists. Of course it must not be understood that automobiles may be built absolutely without regard to their effect on the road surfaces. The best results will undoubtedly be

obtained, and the problem will be solved soonest if endeavors at adaptation are made on both sides; that is, if automobile designers endeavor to build cars having the least destructive effect on existing roads, and if road builders try to provide road surfaces which offer the greatest resistance to destruction by present day automobile traffic.

The authorities of the various States having charge of road construction seem to fully realize the importance of adapting the new roads to the new form of traffic. Treatments for effectively binding the filling material add considerable to the cost of road construction, but the fact is recognized that almost every main road now constructed will be used by automobilists to a large extent from the start, and that if the road is to last it must have the filling material and top dressing securely bound. The various processes of constructing dustproof roads are all quite new, and information as to their relative merits is quite scarce. Probably the best way to encourage invention in this line and to bring the meritorious processes to public notice consists in the construction of experimental roads, adjacent sections of which are built according to the different processes. This enables a good idea of the relative costs to be obtained, and the proximity of the different sections makes it easy to compare roads of the different types after different periods of use, such comparisons being particularly valuable because the weather and traffic conditions have been the same for all sections. The United States Government has built such experimental roads near Washington, D. C., and the States of Ohio and New York are carrying on similar experiments at the present time.

#### Twisting Stresses in Control Rods.

While the twisting stresses which rough roads impose upon the power plant and transmission elements of a car are pretty well recognized and their destructive effects provided against by universal joints, it is not always realized that other minor but not less important operative parts are subjected to stresses of this character and are not always safeguarded against the evil results arising therefrom

Control linkages, the rods of which extend from the chassis frame to various points upon the rear axle, are especially subjected to twisting, resulting from deflections of the axle out of the horizontal when the two rear wheels traverse paths of unequal contour.

Brake pull rods and the shifting rods of rear axle mounted change speed gears come under this head. The voke ends of the rods connecting the ends of the equalizer bar with the bell cranks of the mechanism at the rear hubs suffer a relative change of plane when one side of the axle is lifted or depressed more than the other. A twisting action is thus set up which is more severe in proportion as the rod is of short length. When this twisting action is complicated with the severe stresses arising from the front end of the rod being far out of line with the front end of the distance rod, the material of the rod and the rod ends is very severely tried. These stresses recur very rapidly when a car is driven at speed over rough roads, and may alternate in direction, and it is not unlikely that some disastrous failures of brake riggings have been due to the fatigue resulting from long continued stresses of the above described character. The breakages very frequently occur near the rod ends, where the material is presumably weakened by the cutting of the adjusting

It is of the very first importance that brake pull rods be relieved of all stresses save those imposed by legitimate operation, and the same is true of all other rods extending from the chassis to the constantly vibrating axles. Some makers are providing a universal joint in one end of each pull rod, which acts to prevent twisting stresses. Not only should a very liberal factor of safety be allowed in thse rods, but they should be anchored in front at points so located that they may fully follow the upward and downward movement of the axle along nearly the same arc which it describes under spring action.

#### The Automobile in Military Service.

Every new invention relating to means of transportation or communication is immediately investigated with respect to its applicability for military purposes, especially in Continental Europe, where immense sums are spent annually for armies, and the most stremuous efforts are made to keep the fighting forces up to the highest pitch of efficiency. The automobile has played a more or less prominent part in the annual manœuvres of the German and French armies for years, and the great services

which motor cars may render in times of war are now so thoroughly recognized in these countries that the respective governments are paying bonuses to the owners of certain classes of motor vehicles which are available for the use of the governments in the event of war. Both countries also take up a periodical census of all motor cars over a certain horse power in the country, which are subject to conscription in the event of war, the same as horses.

In this country the possibility of employing automobiles for military work was recognized probably as early as abroad, for as early as 1896 or 1897 Major Davidson, of the Northwestern Military Academy of Highland Park, Ill., made an attempt to demonstrate its value for dispatch bearing purposes by starting on a three wheeled gasoline car from Chicago to New York. The task, however, was too severe in view of the state of development of the industry, and the absolute failure of that experiment would appear to have had a discouraging effect on the Army authorities. That they became rather dubious of the reliability of the gasoline motor may be inferred from the fact that in 1902 the Army adopted electric ambulances. Steam automobiles were also adopted for various purposes, and, aside from the acquisition of a gasoline motor propelled portable machine shop about five years ago the United States Army authorities do not seem to have introduced any gasoline motor cars.

Of late a number of manufacturers have been endeavoring to demonstrate to the authorities the different kinds of work gasoline vehicles can accomplish in connection with military operations. At the recent manœuvres in Massachusetts a 3 ton truck did very creditable service. In February, 1908, while the roads in the Middle West were first deeply covered with snow and then deep with mud, a touring car made a very successful trip, bearing a dispatch from New York to Fort Scott, Ark., and just recently another car has completed a similar dispatch bearing trip from ocean to ocean. We have, of course, had many other demonstrations of the ability of modern cars to make headway under practically all road and weather conditions and of their entire reliability; but these direct demonstrations of the utility of gasoline vehicles in military work should carry particular weight, and the first time the question of improving the equipment of our Army comes up again the automobile certainly deserves consideration.

#### Improvements in the Fuel System.

Instances of the failure of fuel flow to the carburetor in the case of cars equipped with the gravity feed system, when climbing excessively steep grades with nearly empty tanks, have been by no means uncommon during the present season. In some cases the expedient of turning the car around and backing up the hill has had to be resorted to. In several of the 1010 announcements it is to be noted that the carburetor will be placed lower than formerly, so that the difference in level between it and the tank may be increased and a flow assured under more extreme conditions than formerly.

Quite a large proportion of the cars now built are equipped with an emergency or reserve fuel tank, which, as a rule, is merely a compartment within the main tank, the flow from which is independently controlled. This reserve compartment should be, and usually is, in the extreme upper portion of the main tank, and the gasoline within it is thus under ample head, no matter how low the level in the main tank may be. A full emergency tank usually insures immunity from the above mentioned annoyance of arrested fuel flow on excessive grades, and it is rather remarkable that all cars are not fitted with such tanks. The provision of an emergency tank upon the dashboard or a small tank under the hood, which is automatically kept filled from the main tank, constitutes another solution of the problem. In order to secure full benefit from the ordinary form of emergency tank, its contents must be capable of being turned on conveniently and quickly when conditions arise that cause the supply from the main tank to fail. It should not be necessary to raise the floor boards or to take up the cushions and seat boards in order to manipulate the valves. One well known car is now provided with a small hand wheel conveniently placed upon the side of the body. This handle controls both tanks, and usually indicates the "on" and "off" conditions of both the emergency and the main supplies. In this connection it may be remarked that rather more attention is now being paid than hitherto to making gasoline shut-offs accessible. If the gasoline valve is conveniently located, it is a safeguard in case a car takes fire and is more likely to be shut when the car is left standing, thus reducing the likelihood of theft and the danger from fire should the piping or the carburetor develop leaks.

It is believed that if the elevated emergency fuel compartment, with easy means of turning it on and off, is provided on all cars, there will be little need of resorting to the use of emergency air pumps for creating the necessary head to cause fuel feed in gravity systems, except possibly in the case of very long, low hung runabouts, with their front seats very far toward the

#### More Complete Equipments for 1910.

In previous seasons it has been the common policy for manufacturers of low and medium priced cars to furnish a rather meagre equipment, so as to sell the car at as low a price as possible. In the announcements of 1010 models a great change is observable. Quite a number of manufacturers are furnishing their cars with a very complete equipment, and some of them have even increased the selling price in order

Even though the car is sold at a higher price in order to include a liberal equipment it may still prove a good bargain to the buyer, for the maker usually gives the customer at least part of the very considerable saving which comes from buying equipment in large quantities.

Many people wonder why cars are not more generally listed at two prices, one with and the other without equipment. But as a matter of fact it is of considerable. advantage to a manufacturer to know from his orders as soon as possible just how many of each article of equipment he will require for his season's output. If he can tell this he can buy to much better advantage, and, of course, can furnish the material to the purchaser much cheaper. So, as it is advantageous to both maker and user, we may expect the practice of furnishing a rather liberal equipment to become common.

#### Coming Events.

September 21 to 29-Munsey Reliability Run, Washington, Boston and return.

October 7-Philadelphia (Pa.) Second Annual 200 Mile Stock Chassis Race in Fairmount Park, Quaker City M. C.

October 30-Vanderbilt Cup Race, Long Island Motor Parkway, Long Island, N. Y.

November 6 to 13-National Automobile Show under the auspices of the N. A. A. M. at Atlanta. Ga.

November 9-Atlanta, Ga., Track Races, Atlanta Automobile Association.

November 22-Flag-to-Flag Reliability Run, from

Denver to City of Mexico. 29-30-Philadelphia

Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7-New York City Asnual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

January 8 to 15-New York Annual Show, Medison Square Garden, Association of Licensed Astomobile Manufacturers.

#### Advantage of Offsetting Cylinders.

A paper on "Offsetting Cylinders in Single Acting Engines," read by Prof. T. M. Phetteplace before the American Society of Mechanical Engineers, has brought out a rather interesting written discussion, which is published in the latest issue of the society's Proceedings.

Winslow H. Herschell states that in December, 1907, he had occasion to investigate the question of offsetting cylinders for large sized gas engines, the conditions being somewhat different from those of the automobile engines considered by Professor Phetteplace. Only the variations in maximum and average pressure on the cylinder walls are considered, these being the main questions at issue

For the sake of simplicity the graphical method mentioned in Tolle's Die Regelung der Kraftsmaschinen, page 32, was used. The computations were based on an actual card from a four stroke cycle producer gas engine, and upon the following data:

R. P. M. = N = 225 W/A = 4.18 R = 12 inches = 1 foot L/R = 50.00034 W/A N<sup>2</sup> R = 71.8

This last value, 71.8, happens to be very nearly the average of the two corresponding values, 34.4 and 111.38, given by the author. Computations were also made using speeds of 450 and 1,000, giving inertia constants of 289 and 1,430, respectively, but it soon became evident that there could be no gain from offsetting under these conditions, and the investigation was restricted to the speed of 225.

The author of the paper considered only vertical engines, or horizontal engines where the weight of the reciprocating parts is so small that its direct effect in increasing or decreasing the pressure on the cylinder walls need not be taken into account. In the present case, however, a distinction must be made between vertical and horizontal

engines. For the latter, when the side pressure acts downward, due to gas pressure or inertia forces, the weight of the piston must be added, but when the side pressure acts upward the piston weight is subtracted. It should be noted that for a vertical engine, for a given value of 0.00034 W/AN2R, that is, for a given inertia constant, it would make no difference whether this value were obtained with a large value of W/A and a small value of N, as in the present case, or with a small value of W/A and a large value of N, as in the cases used by the author. But, on the other hand, it would make considerable difference for a horizontal engine where the value of W enters

ertia forces we have line GH for a vertical and line JK for a horizontal engine,

It will be noticed that line JK is not parallel to line GH. The reason for this is that for the line JK we must use the inertia force near the end of the second stroke, which gives a downward pressure on the cylinder walls to be added to the weight of the piston, and this downward pressure is not as large as the upward pressure near the beginning of the second stroke, which was used for the line GH.

In the case of a two stroke cycle engine, where we must use the fourth instead of the second stroke, our maximum inertia force will be near the beginning of the fourth

TABLE I .- OFFSET AND PER CENT REDUCTION IN SIDE PRESSURE.

Curves.	Dominating Factors.	Case,	Offset.	Gain.	
	Gas middle first, inertia beginning 2d.	Vertical late ignition, 2-4 cycle.	37.0	41.5	
	Gas middle first, gas beginning 1st.	Vertical early ignition, 2-4 cycle.	28.7	31.6	
DE and JK	Gas middle first, inertia end 2d.	Horizontal late ignition, 4 cycle.	37.7	34-7	
DE and QR	Gas middle first, inertia beginning 4th.	Horizontal late ignition, 2 cycle.	61.3	54-3	
DE and JK	Gas middle first, inertia end 2d.	Horizontal early ignition, 4 cycle,		34-7	
DE and NP	Gas middle first, gas beginning 1st.	Horizontal early ignition, a cycle.	40,6	37.2	

into the computation apart from the inertia constant.

By using the same indicator card as for the four stroke cycle computations, and disregarding the second and third strokes, the approximate side pressures for a two stroke cycle engine were obtained.

Fig. 1 shows the variation in the maximum pressure of the cylinder walls, or side pressure, due to variations in offset. The ordinates above the base line ST are proportional to the side pressures. The line A B shows the maximum side pressure for a vertical engine at about the middle of the first stroke. As the offset increased the angle of the connecting rod for this middle position decreases, while the angle at the end of the stroke increases, so that for large offsets the maximum side pressure is found at the end of the stroke, with values as shown by line BC. Similarly, for a horizontal engine we get the lines DE and EF. For the maximum side pressure due to instroke acting upward, so that the weight of the piston must be subtracted, giving line Q R.

If we imagine a somewhat earlier ignition than that shown in Fig. 2 of the paper, the maximum side pressure at or near the beginning of the first stroke will be increased. Whether for this reason or not it was found that with large offsets the maximum side pressure of the first stroke was at the beginning of the stroke, acting upward, with values as shown by line L M for a vertical, and line N P for a horizontal engine.

Table I gives the offset and the per cent. reduction in side pressure in each case.

The author of the paper found the most favorable offset to be 50 per cent. of the crank length for slow speed, and about 20 per cent. for high speed. These values may be compared with the first line of Table 1; for the case of a vertical engine with late ignition, the offset is 37.0 per cent., which is nearly the average of 20 per cent. and 50

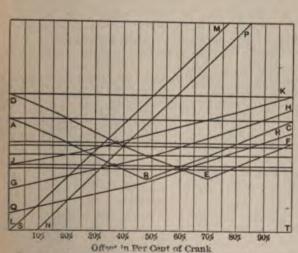

Fig. 1.—Diagram Showing Variation in Maximum Pressure on Cylinder Walls Due to Offsetting Cylinder.

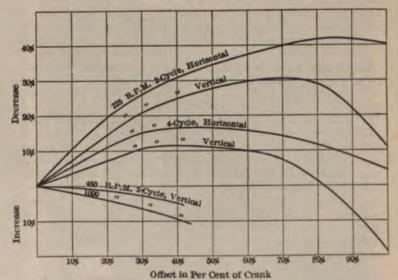

Fig. 2.—Diagram Showing Change in Average Pressure on Cylinder Walls Due to Offsetting Cylinder.

per cent., as might have been expected from the inertia constants.

Fig. 2 shows the decrease or increase in average side pressure or total loss of work from side pressure in per cent. of lost work with zero offset. While the use of a different indicator card with a later ignition might have made some difference, it obviously could not have changed the result so materially as in the case of maximum side pressure.

The curves marked 450 and 1,000 r. p. m. show the results of the few computations concerning these speeds not considered in Fig. 1.

Both Table 1 and Fig. 2 appear to indicate that more could be gained from off-setting with a two cycle than with a four cycle engine. But at present it is difficult to make general statements about this type of engine, and whether or not this advantage will be attained will depend upon the inertia constant and indicator card shown by these engines.

#### PRINCIPAL CONCLUSIONS.

- a. An offset cylinder may be employed with least benefit on a high speed, four stroke cycle vertical engine.
- b. It may be employed with most benefit on a slow speed, two stroke cycle horizontal engine.
- c. The maximu advantageous offset is limited by the side pressure near the beginning of the first stroke.

## Cornell University to Make Road Tests.

The engineering department of Cornell University, Ithaca, N. Y., has arranged with the United States Office of Public Roads to conduct a series of comparative tests of road building materials. A road consisting of a number of different materials will be built, the road to be utilized for this purpose being a continuation of the State road at East Ithaca, N. Y. It will be constructed in sections of brick, concrete and bituminous macadam of different kinds. Nearly a dozen manufacturers of bituminous macadam have decided to co-operate with the university authorities.

## Cleveland Auto School Changes Hands.

The automobile school formerly conducted by the Central Y. M. C. A. at 2160 East Ninth street, Cleveland, Ohio, has been purchased by C. H. Pratt and W. B. Pettibone, former principal and instructor of the school, and M. N. Fowler, former educational director of the Central Y. M. C. A. The school opened September 27 with both day and night classes. The evening class meets two evenings each week, and completes the course in three and a half months. The day class meets every day and completes the course in four weeks. The course consists of fourteen explanatory lectures, shop practice and twelve driving lessons. New day classes are opened each month, and evening classes every two months.

#### Motor Fire Appliances in Glasgow.

It is nearly four years since the corporation of Glasgow introduced motor power into the service of its fire department, and the results have been so satisfactory from every point of view that it is the intention to gradually substitute motor fire vehicles for steam fire engines, so that ultimately horse and steam power will be entirely dispensed with.

Detailed specifications for a gasoline driven motor fire brigade tender, covering the following accessories and appliances, have been transmitted by Consul McCune, and are on file in the Bureau of Manufactures, Washington, D. C., and cover engine, carburetor, ignition, cooling, gasoline tank, lubrication, clutch, gear box, wheels, back and front axles, steering, frame, wheel base and wheel track, springs, brakes, body, outfit and fire escape; also for chemical engine, its composition and weight.

There are in the central district of the city fire department three gasoline engines, which have each four cylinders and are capable of developing 50 to 55 horse power. Equipped with 12 feet of canvas hose, 25 feet of suction hose and other necessary gear, and manned by ten men, they easily maintain a speed of 30 miles an hour. They are provided with duplicate systems of ignition, one by high tension magneto and the other by accumulators and trembler coil. The pumps are geared to the gasoline motors by means of shafts runnig down the centres of the vehicles, having spur wheels engaging with steel pinions on the first motion shafts of the gear boxes. These pinions can be thrown in and out of gear by hand levers operated from the sides of the machines, enabling the pumps to be instantly put to work on arrival at a fire.

The change speed gears have three speeds forward and one reverse. The wheels of the machine are interchangeable. The weight, manned and fully equipped, is 4 tons 8½ cwt.; length, 14 feet over all; wheel base, 9 feet 8 inches; track, 5 feet 6 inches.

When stationary, and pumps working, cooling is maintained by supply from the delivery to the cooling tank, the water being allowed to flow away through the overflow-pipe. These pumps are of the turbine type.

FIRST AID MOTOR AND MOTOR FIRE ESCAPE.

The department has also in use a motor first aid machine to carry an officer and twelve men, with 650 yards of 2½ inch canvas hose, 18 feet of scaling ladder, in two lengths, ambulance box on rear footboard, and all necessary tools and gear. It is a four cylinder, 24 horse power machine, and weighs when fully equipped and manned about 3 tons. It has four speeds forward —7, 11, 16 and 22 miles an hour—and one reverse.

At present the department has but one motor fire escape, which carries an extension ladder of 85 feet on a turntable. When traveling the machine is 26 feet long, 10 feet high, weighs 6!2 tons, and is driven by a four cylinder, 30 to 40 horse power gaso-

line motor, with battery and magneto ignition. The gasoline motor drives a dynamo or generator, which transmits the current, through flexible cables, to two electric motors, hung on the front axle and geared up to the front wheels, which have solid rubber tires. There are five speeds forward, up to 20 miles an hour.

The control of power and brakes is by one hand lever, situated below steering wheel. The machine is easy to drive and steer, and, owing to the extremely quick action of the electric brakes, can be safely handled in heavy traffic. The ladder, when raised from its horizontal position on the carriage to the angle at which it is desired to work, is extended by means of a small engine, bolted to the side of the main ladder. and driven by carbonic acid gas, the gas being contained in four cylinders fastened on the turntable. Enough gas is contained in the cylinders to extend the ladder a number of times without refilling. Automatic safety catches are fitted to the sliding ladders for security in raising or lowering. An oil brake is fitted to the foot of the ladder to allow of ladders being lowered without using winch handles. All the bearings throughout are anti-friction, ball or roller, and the releasing gear, to unlock ladder by same action, takes weight of whole machine off back springs, thereby preventing any chance of the ladder, when in action, sagging to either side. The machine has a 12 foot 4 inch wheel base, and a 6 foot track, and its stability is such that, while self supporting, four men can safely manipulate two lines of hose from any desired position on the ladder.

#### British Motor Spirit Imports.

Consul J. N. McCunn, of Glasgow, makes the following report on the increase in the consumption of motor spirit in Great Britain:

"Official statistics show that during the past few years the sale of motor spirit has developed enormously in this country, and that expansion of the business continues. Over 32,000,000 gallons were imported in the six months ending with June, 1909. 12,000,000 gallons more than in the corresponding six month of 1908, and upward of 17,000,000 gallons more than in the same period of 1907.

"Fully 50 per cent, of the total supply of gasoline imported into the United Kingdom is received from the Dutch Indies. The United States is a good second in furnishing the supplies, having new producing fields of high grade oil. During the first six months of 1909 the United Kingdom thus secured about 10,000,000 gallons of American motor spirit, fully 8,000,000 more than in the corresponding six months of the previous year. Russia is pushing its motor spirit export trade with great energy and heavy shipments from the Grozny field are now reaching the British market. . The new oil producing countries exporting to Great Britain are Roumania and Mexico.

#### The Haynes Model 19.

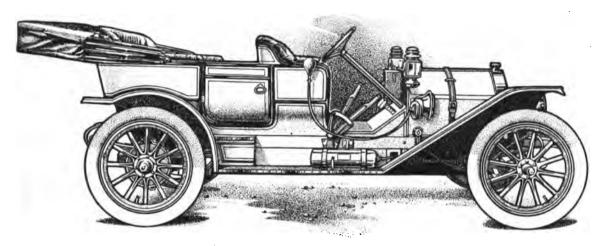

In addition to the large car which they have been manufacturing for the last several years, the Haynes Automobile Company, of Kokomo, Ind., are bringing out for 1910 a five passenger "30," which they are making a leader. Since the former car is too well known to require descrip-

warm water discharged from the top over the combustion chamber. These water jackets are designed so that the greatest amount of water is at the top of the cylinder, where the temperature is the highest. A large opening over the water jackets provides for the removal of core sand, and also provides for the easy inspection of the cylinder casting at any time. A large brass plate covers the cylinder head, and forms an outlet through which the heated water passes to the radiator.

The compression in the cylinders is 65 pounds. The inlet valves and carburetor

and also a dental clutch between the pump and magneto, which latter is situated at the rear of the pump. This arrangement of joints allows for the removal of either pump or magneto without disturbing the other.

The valves are 2½ inches in diameter, have a thirteen-thirty-second inch lift, and are interchangeable. They have three-eighth inch diameter stems. The valves are mechanically operated by two cam shafts, one on either side, and are actuated by cams and roller lifters. The valve lifters are drilled and tapped in the top, and an

THE NEW HAYNES LIGHT CAR MODEL 19.

tion, the smaller car will only be dealt with in this article.

The cylinders are of gray iron, cast in pairs, with offset intake and exhaust valves on opposite sides, the motor being of the well known T type. The cylinders are bored, reamed and ground to size. The cylinder dimensions are 4½ inch bore by 5 inch stroke. The water jackets are spacious, and the cool water is taken in on the exhaust side of the motor, and the

are located on the right side of the motor, the carburetor (a Stromberg) being located midway between the cylinders in such a position as to afford convenient adjustment. The exhaust valves are located on the left side, and directly beneath the exhaust manifold are located the water circulating pump and the magneto, both of which are driven by the same shaft and gear. There is, however, a joint in the shaft between the pump and driving gear.

adjusting screw is inserted, with a lock nut, which allows for close and accurate adjustment of the valves at all times. The valve lifters work in cast iron guides, and are hardened and ground, as are the valve stems. The valve seats are also ground. Nickel steel valve heads are used, which are electrically welded to the stems. The valve springs are held in place with a key and cup, the cup being counter bored to receive the spring and hold it in position.

HAYNES MOTOR, INTAKE AND EXHAUST SIDES.

The pistons are long, and are turned and ground to the proper diameter. Each piston has three compression rings and a snap ring to hold the piston pin in place. These rings, which are not eccentric, are ground on three sides, and have a 45 degree joint.

The piston pin is made hollow, to aid in oiling the bearing; it is of 3½ per cent. nickel steel, one inch in diameter, and held in place, as before stated, by a snap ring around the outside of the piston.

The cam shaft shows careful thought as

The crank case is cast of aluminum alloy, in two pieces. The top portion contains a compartment or housing for all gears. These gears run in an oil bath, and are thus protected from wear and are quiet in operation. The lower half contains the oil reservoir, and is entirely independent of the crank shaft bearings. This lower half has a well the full length of it, into which the surplus oil from the splash pans runs, and from where it is pumped by a small gear pump back to the bearings. A constant level of oil is maintained in the

ened by one edge being turned at right angles to the blade, this stiffening rib being one-quarter inch high. The fan runs at two and one-half times the engine speed.

The water pump is a gear pump, with a good sized sediment chamber below it, in which is inserted a wire gauze cone. This cone strainer prevents any foreign substance, such as solder, getting into the pump gears and causing damage. The pump shaft is supported on both sides of the pump gears by liberal bearings. On the outer ends of these bearings are stuffing boxes, which are easily accessible for repacking. These bearings hold the pump shaft in perfect alignment, and the stuffing boxes take care of any possible leakage.

A cellular radiator is used, and the whole system holds 5 gallons of water. A breather pipe is located on the right hand forward crank case arm to relieve the crank case compression, and is so situated as to entirely avoid any splash of oil through it onto the motor or hood. A Splitdorf low tension magneto is used, with a non-vibrating coil, which is located on the dashboard. A single glass sight feed is also located on the dash for the oiling system.

The clutch is the well known Haynes contracting band type, 14 inches in diameter and 2 inches wide, with steel working against bronze. It can be adjusted very quickly. The clutch is now piloted on the end of the crank shaft, which keeps it perfectly central and insuring smooth, uniform engagement.

A sliding gear selective type transmission is used, with Timken bearings throughout. Liberal gear surfaces are used, but the whole gear is very compact and is located underneath the footboard, where it is easy to get at. All gears in the transmission are of nickel steel, harveyized, and run in oil, the gear casing being oil tight. A propeller shaft, with double universal joints, transmits the power to the rear axle. The yokes of the universal joints are slotted, hardened and ground. In these slots

DRIVE SHAFT.

to bearing size and location. Each shaft is one inch in diameter, and has four bearings. The front bearing in the outer gear casing is 1¼ inches long; the next bearing, inside the cam shaft gear, is 2 17-32 inches long; the centre bearing is 6 inches long, and the rear bearing 2½ inches long. The long bearing in the centre tends to prevent the shaft from springing away under the pressure on the cams when in operation. The cam shaft is made of 0.40 per cent. carbon steel, hardened and ground. The cams are of nickel steel, heat treated and pinned to the shaft with hardened nickel steel pins.

The connecting rods are drop forged and to inches long. The top or piston pin end is split and provided with a screw and lock nut for tightening the piston pin bushing. This bushing is made of phosphor bronze, and is 2¼ inches long. The lower end of the connecting rod has a marine type bearing into which are fitted nickel babbitt bushings, with provision for adjustment. The lower bearings are 2 inches long and 1¾ inches in diameter. All the bearings on the crank shaft are of nickel babbitt.

The crank shaft is drop forged, with all bearings 134 inches in diameter, and has a combined bearing length of 133% inches. It has four bearings, the rear bearing, next to the clutch, being 434 inches long, the centre bearing 31/2 inches, the next bearing 334 inches, and the front bearing in the outer gear casing 13% inches long. At the extreme end of each of the end bearings on the crank shaft is turned a small cone shaped flange, which prevents the oil from working out of the end of the bearing onto the motor and parts. The oil flung off by the flange is caught in a small reservoir and returned to the crank case. The flange to which the flywheel is bolted and keyed is forged integrally with the crank shaft.

Great care is used to obtain perfectly balanced reciprocating parts. The connecting rods and pistons are finished to uniform weights and carefully balanced. A cast iron flywheel, 18 inches in diameter 1 weighing 82 pounds, is used.

connecting rod splash pans. The oil pump is placed at the rear of the motor on the right hand side, and operated from the inlet cam shaft. The oil pump drive shaft is so arranged that a timer can be attached if so desired.

The inlet manifold is T shaped, having but two outlets, with the inlet from the carburetor midway between the outlets. Each pair of cylinders has an inlet chamber common to both cylinders in the pair. The exhaust is arranged in a similar manner, the exhaust manifold being slightly tapering and connecting through a long pipe to the Kingston muffler, located at the rear end of the chassis.

The cam shaft gears are of open hearth steel, cut with helical teeth, and mesh with the steel pinion on the crank shaft. The water pump and magneto driving gear are driven from the exhaust cam shaft gear. Each of these several gears has a bearing on both sides, which prevents any springing away under load.

The fan is located on the top of the gear compartment, and provision is made for adjusting the belt. The fan has a ball bearing hub, and the blades are strength-

CLUTCH BAND AND GEAR BOX.

hardened and ground trunnions which in turn work on hardened and d pins. The rear joint is flanged, and lange bolts to a corresponding flange e bevel pinion shaft. This arrangepermits of removal of the rear axle ut taking down the universal joints. rear axle is of the full floating type, a pressed steel differential housing. a bevel gear and pinion drive, with er gear differential. Large Timken bearings are used on both sides of fferential case, which, of course, take e end thrust. Two Timken bearings ed on the driving pinion, and take up nd thrust on it.

rear axle drive shafts are of nickel squared at the ends. The inner ends o the differential gears, while to the ends the wheel hub flange is shrunk. seems to be a departure from the ordiaccepted method, as the flange is ted to the wheel by the hub bolts. method reduces the wearing surfaces ninium. The torque rod is of pressed

inches narrower in front, to increase the turning range.

Semi-elliptic springs, 39 inches long, 2 inches wide, with six leaves, are used in front, and three-quarter scroll elliptic, 41½ inches long, 2 inches wide and with six leaves, are used at the rear.

The speed control and brake levers are short, and are located at the correct angle to give comfort in manipulation. These levers are drop forged. The speed lever works in an H slot, the emergency brake lever on a ratchet quadrant.

The brakes are internal expanding and external contracting, the internal brake being the emergency or hand brake, and the external the service or foot brake. Both are provided with equalizers, and neither brake is connected with the clutch in any way.

A copper gasoline tank holding 18 gallons is located under the front seat. The front fenders are long and rakish, giving the car a good appearance, while both fenders are designed to protect the occupants of the car from mud and splash. The hood is

REAR AXLE.

of channel section, and is supported at

wheels are 34x4 inch, with twelve s and Marsh standard quick detachans for all four wheels. Brake drums hes in diameter and of 21/4 inch face tached to the rear wheels. The front is a one piece drop forging of 21/2 It is set at 15 tons. The pads are forged integral. The wheel es are It inches in diamter, and fittih Timken bearings. The steering of good length and insures comfort ving. All steering connections are of Il and socket type, and a 17 inch steerheel, with metal spider, is used. The ig wheel turns independently of the I levers, which latter move over a quadrant on top of the wheel. The ig gear is of the worm and gear type, orm gear being a complete wheel. By g the steering wheel through five comrotations with the steering levers disted an entirely new wearing surface

frame is of pressed nickel steel of el section. It is dropped 2 inches in of the rear axle, lowering the centre wity, making the car easier to handle asier riding. The frame is made 4 271/2 inches long and 21 inches high, and is of oval design. Plenty of room is left between the front seat and the dash, while pedals of different length can be had to accommodate either a short or a tall person. The steering column is set at a comfortable angle for driving, being neither too far away nor too close. The distance between the front seat and the dash is 25 inches; the depth of the front seat, 10 inches; the distance from the back of the front seat to the front of the rear seat, 25 inches; the depth of the rear seat, 19 inches; the width of the rear seat, 50 inches; the height of the rear seat, 141/2 inches; the extreme length, 153 inches.

The body is low and well proportioned. Steps over the brake levers into the tonneau facilitate ingress and egress. The color of the cars is either blue or green. The equipment includes five lamps, viz., two large gas lamps, two square side oil lamps and one round oil tail lamp; also a Prest-O-Lite tank, Diamond tires, a brass tube folding front and a top. Deliveries of these cars will begin October 1.

A new car called the Paige has appeared on the streets of Detroit. It has a three cylinder, two cycle engine.

#### The Regal "Thirty" for 1910.

The 1910 model of the Regal 30 is a continuation of the 1909, except for some minor changes not affecting the principles of construction, but adding to the convenience of the user or improving the operation of the car.

The motor is still a 4x4, with all valves on one side. A leather faced cone clutch, enclosed, grease tight universal joints, and a three speed selective transmission located on the rear axle are other features that are retained. The wheel base has been lengthened 2 inches, making it 107 inches. The body has been made a little roomier and the lines thereof have been improved, and this, together with the curved dash and new fenders, gives the car a somewhat different and improved appearance.

The engine has been refined in several particulars. The pistons now are fitted with three rings above the piston pin and one below, thus giving additional insurance against compression leakage and preventing an excess of oil from getting past the piston if at any time too much of the lubricant should be poured into the case by a careless user. A pressed metal float has been provided in the lower case which indicates the height of the oil by means of a stem which extends from the float up through a glass tube located on the upper crank case. As this tube is air tight and the oil never gets into it, it is always clean and the stem is easily seen. Any sight tube that contains oil will very soon become dirty and make it almost impossible to determine the level.

The fan has been removed from the radiator and is now placed on an adjustable bracket attached to the cylinders and braced by the lower crank case. This fan, equipped with ball bearings, is driven with a V belt and needs oiling only once or twice a season.

A gear pump is provided, as formerly, except that the housing of the pump is made in one solid piece, thus saving about onehalf the weight and doing away with the possibilities of a leak at the union of the two castings.

A long cylindrical strainer is provided at the intake, and the oil is discharged through a steel tube onto the main bearings. An overflow returns the oil to the reservoir, which holds about 1½ gallons.

A breather pipe about twice the capacity of the old one has been provided, which not only effectively relieves any crank case pressure but also provides a very easy means of filling the oil tank. A baffle is provided in this breather pipe which effectively prevents oil from being thrown out.

If a cam shaft has but a very slight end play in its bushing it will cause a knock, which is sometimes very hard to locate. To guard against this trouble the rear end bushing is threaded so that it may be moved backward or forward to adjust it endwise accurately, slots being cut in the bushing to hold it from turning by means of a

THE REGAL "THIRTY" 1910 MODEL

dowel pin while it is being moved endwise.

The Regal has a thermo-siphon cooling system which is said to have proven so successful that not a single complaint has been received on the whole year's output. The accompanying cut shows the principle of its action, and while it is very similar to the ordinary arrangement, it has some points which make it more efficient.

If the pipe extends from the engine to the top tank of the radiator a slight lowering in the water level will leave an open spot in the system so that the water will not circulate, except in spurts when enough steam has been generated to push the water over the intervening space. To overcome this difficulty the pipes have been lowered so that they rise on a silghtly inclined line, which permits the water level dropping to a much greater extent before the circuit is broken. Now, should this central tank extend entirely through the radiator there would be a hot stream of water tending to rise, which upon cooling would tend to drop through the same tube, so there would be two forces in opposite directions. In the Regal system, however, the tank extends only half way through the radiator, so that the hot water rises at the rear, becomes cooled, and descends through the front of the radiator, so that there is an uninterrupted flow. To further facilitate the circulation a 2 inch pipe is used at the bottom and two 13/2 inch pipes are used at the top, which, together with the free passage through the water jackets, allow an uninterrupted flow, which is necessary in a successful thermo-siphon system.

The leather faced cone clutch has proven entirely satisfactory, so that no changes have been made. This applies also to the universal joint in the ball end of the propeller tube.

The transmission, located on the rear axle, has been improved by the use throughout of high duty nickel steel Hyatt bearings. All these bearings are encased in solid, hardened and ground bushings, and run upon the hardened and ground ends of the shaft itself.

The shafts and gears are all of nickel steel, the gears being cut with teeth especially constructed for strength at their base. The diameter of the rear axle tubes has been increased from 2 to 2½ inches, to make a more rigid construction, and to further improve this member the axle shafts are now made of nickel steel.

The most frequent cause of noisy gears in the rear axle is the lack of adjustment for the driving pinion and bevel gear, which is attached to the differential. On many cars there is no adjustment in either case, but this construction is fitted with an adjusting collar which will move the small bevel pinion back and forth, while two other adjusting collars are found in the rear axle which will move the large bevel gear in either direction, so that it is possible to accurately adjust these gears for noiseless operation.

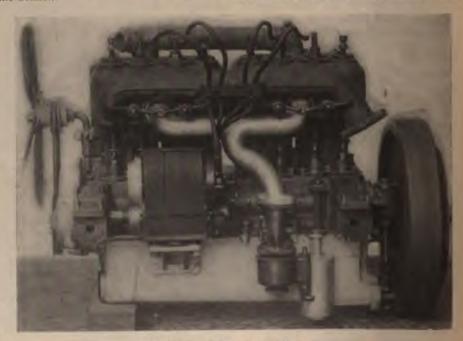

The lines of the body have been improved by slanting the seat backs slightly more toward the rear, making one straight line along the arms of the seats and the top of the door, and by making the door plain without a break at the middle. The seats and the doors are made of sheet metal, while the material of the under body is wood, as heretofore. More clearance has been provided between the wheel and the fenders, and the dash has been curved at the top to follow more closely the top of the bonnet.

Cadillac 1910 Model.

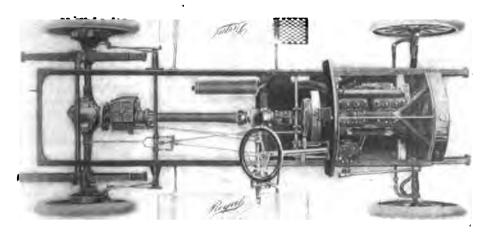

During the coming season the Cadillac Motor Car Company will again devote themselves to the production of a four cylinder, 30 horse power model. The new "Thirty" will be very similar to this season's car. Indeed the mechanical details are almost identical, and readers who desire a more complete description of these than is here given are referred to the description of the 1909 car, which appeared on page 932 of Vol. 22.

The new car is slightly larger than its predecessor. This increase in size is most apparent in the motor, which has been enlarged enough to make the car more powerful in proportion to the car weight than the former model. Its bore has been increased from 4 to 4¼ inches, but the stroke remains 4½ inches. While the A. L. A. M. rating is slightly under 30 horse power, the motor is said to develop 33 horse power on continuous dynamometer test.

The cylinders are cast separately, with the typical Cadillac copper water jackets and attached heads. Valves are all on one side. The crank shaft has five plain bearings. Lubrication is by splash, with oil level maintained by a mechanical oiler which circulates the oil through a sight feed on the dash. Cooling is by water circulated by a gear driven gear pump. The fan is mounted on two point ball bearings, and is driven by a V belt. In this season's car a magneto is supplied as part of the regular equipment. The Webster magneto is fitted, a new type which we expect to describe in a short time. It works on the low tension system, has a vertical shaft, and the motor may be started from the seat with this system as well as with the battery system. The battery system is the "Delco," which comprises a four unit coil attached to the motor, and a special switch on the dash. The battery consists of dry cells, carried in a metallic case under the front seat. When

REGAL THIRTY HORSE POWER MOTOR.

PLAN VIEW OF REGAL CHASSIS.

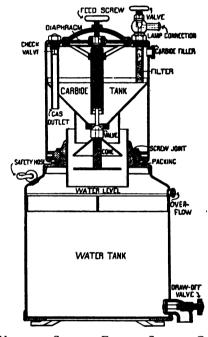

the dry cells are being used the ignition is by single spark, so the cells last for a long

The clutch is a leather faced cone with the male member cut in several places to give easy engagement. The change gear is a sliding selective, giving three forward speeds and a reverse. The drive to the rear axle is by a housed shaft, with enclosed globe joint to the frame, and single universal joint within the globe. Lubricant is supplied from under the seat, through a tubular connection. The rear axle and driving shafts are mounted on balls at their inner ends and on Hyatt rollers at the wheels. The axle housing is made from pressed steel. The front axle is an Eliott type forging of I section, whereas last season a tubular axle was used. The wheels run on two point bearings, and the pivots are provided with hall thrusts

As in the 1909 car, semi-elliptic springs are used in front and three-quarter elliptics in the rear. The dimensions are: Front, 36x2 inches; rear side springs, 42x2; cross spring, 38x2 inches. The side members of the frame are bent upward above the rear axle to give the proper clearance and bring the centre of gravity low. The height of the car is thus about the same as in this season's model, in spite of the larger wheels. At the rear the frame is 33 inches wide, but at the front it is narrowed to 30 inches. The steering gear is of the worm and sector type, with the case for the gear set placed rather higher than usual, so that the levers at the lower ends of the central control shafts are conveniently located for connecting to the timer and the throttle. The steering wheel is 17 inches in diameter. Both sets of brakes are on the rear wheels, the external brakes are operated by a pedal and the internal by a hand lever. Gear shifting is controlled by a hand lever working in an H slot.

The tire sizes have been increased from 32x31/2 inches to 34x4 inches. Quick detachable rims are provided. The hub flanges and spokes have been made heavier to correspond with the increased diameter. The wheel base has been lengthened to 110 inches, as compared with 106 inches on the previous model. This increase has permitted the use of a more roomy body. The tonneau seat is wider and there is more foot room. The tread is 56 inches.

The 1910 car is sold at \$1,600 instead of at \$1,400, on account of its more expensive

VERTICAL SECTION ELLIOTT STORAGE GEN-ERATOR.

cessories being included in the price of the

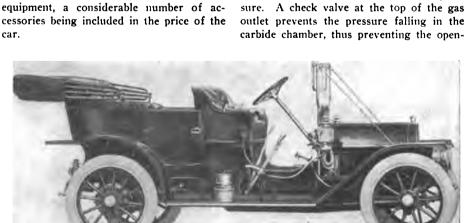

#### The Elliott Storage Generator.

This generator, manufactured by the Eco Manufacturing Company, of 53 State street, Boston, is of the carbide feed type, a principle which has not hitherto been applied to acetylene generators for automobiles. The gas is generated under a pressure of about 4 pounds, and as there is considerable storage space, gas may be available at all times, thus giving many of the advantages both of the ordinary generator and gas tank. In size this generator is only slightly larger than the ordinary type more frequently met with.

As can be seen from the section, the device is remarkably simple. The carbide chamber is above the water reservoir and is closed at the bottom by a conical valve which in operation is held open by a spring against the action of the gas pressure on a diaphragm. When the pressure rises above a certain predetermined point (about 4 pounds) the pressure of the gas on the diaphragm raises the valve to its seat, thus cutting off the feed of carbide. When the pressure falls the spring acts to open the valve against the pressure of the gas. The fluctuation is very slight, being only about 2 ounces.

The construction is such as to insure good, cool, dry gas being fed to the burners, the gas after generation being cooled by its passage through the water. It then passes through an outlet tube from the top of the water tank to the top of the carbide tank. It must then pass downward through the carbide to the bottom of the filter tube, from where it passes through the valve to the lamps. It will be readily seen that any moisture which may have passed over with the gas will be absorbed by this body of carbide.

There are quite a number of interesting features on this generator. One is the safety valve. This consists simply of a T on the top of the water tank. The ends of the T are closed by a short piece of rubber tubing bent round and embracing both ends. In case of the pressure rising to an abnormal degree the tubing will be burst, thus forming an exit for the reserve pressure. A check valve at the top of the gas outlet prevents the pressure falling in the

THE CADILLAC "THIRTY."

THE DEMOT.

ing of the feed valve, and also giving an opportunity for the replacement of the rubber safety tube, the burners in the meantime being supplied by the gas stored in the carbide chamber.

The water reservoir is emptied of the slacked carbide through the draw off cock. With this so situated as to drain directly on the ground, it can readily be seen that this can be easily and quickly cleaned out with a hose when the carbide chamber is removed.

#### The Demot Car.

The recently organized Demot Car Company, of Detroit, have announced the specifications of their little runabout, which are briefly as follows:

The car is strictly a two passenger machine, light and handy, designed so it can be well made and still sell at a low price. The cost of up-keep should also be quite small. Power is supplied by an opposed motor set crosswise in front. It has a 31/2 inch bore and 3 inch stroke, and is water cooled, using a vertical tube radiator and thermo-siphon circulation, without fan. Ignition is by magneto and dry cells. Lubricant is supplied by crank case pressure, and also by splash. This engine design is the result of a long series of tests. A large speed range is claimed to be obtained with automatic inlet valves. The inlet pipe is water jacketed. The motor is set in an aluminum casting, which also carries the change gear, and serves both to line up the power plant and to protect it from dirt.

The change gear is of the planetary type, giving two speeds and a reverse. The control is selective, by a single hand lever. Connection to the bevel rear axle is made through a propeller shaft with two universal joints. No torsion member is provided, the torque being taken by the semi-elliptic rear springs, according to the plan first adopted by the Hotchkiss Company. Ball bearings are used on the shaft for the driving pinion. Plain die cast bushings are used on the differential end of the axle shafts. Hyatt roller bearings are used at the wheels. The axle is, of course, of the fixed hub type. The front axle is a square section forging, which is claimed to be more practical than an I section for a car of this size. The front wheels are ball bearing. All four springs are of the semi-elliptic type. The frame is of pressed steel, and is straight. The wheels are 30 inches in diameter, fitted with 3 inch tires. The wheel base is 80 inches, and the tread is standard. Steering is by an irreversible gear. Pedal operated expanding brakes act on the rear hub drums. The weight is given as 800 pounds. Two side and a tail oil lamp, a dragon horn, tire repair and tool kits comprise the equipment.

#### The Great Western "Thirty."

The Great Western Automobile Company, of Peru, Ind., have just completed the first car of a new model, to be known as their "Thirty," of which a photograph is shown herewith. The cylinders have a bore of 41/4 inches and the piston stroke is 5 inches. The car has a gasoline tank of 20 gallons capacity. Ignition is by high tension magneto. The motor is lubricated by a gear driven mechanical oil pump integral with it. The cooling water is circulated by means of a gear driven centrifugal pump. The radiator action is enhanced by a ball bearing, readily removable fan. The clutch is of the conical type and is lined with a composition that is claimed to insure smooth engagement. A three forward speed and reverse, selective type of change gear is employed. The drive to the rear axle is by an enclosed shaft with a single universal joint. The rear axle is of the semi-floating type, while the front axle is an I section drop forging, forged in one piece with integral spring seats. The car has a pressed steel frame, narrowed in front to permit of turning in a short radius, and dropped in the rear to insure a low centre of gravity. The frame is carried by 48 inch semi-elliptic front springs and 52 inch three-quarter elliptic scroll springs. It has a wheel base of 112 inches and is made with either a 56 inch or a 60 inch tread. The wheels are 34 inches in diameter and fitted with 31/4 inch tires on detachable rims. The car is fitted with two separate pairs of brakes, of the internal expanding and the external contracting types, respectively, both acting on pressed steel drums secured to the rear wheels. The photograph herewith shows the car equipped with a four passenger short coupled body, but the standard body is a five passenger tonneau with divided front seats. The standard color is coach blue with cream running gear. Spark and throttle levers are mounted on top of the steering wheel, and the engine may also be controlled by means of a foot accelerator. A very complete equipment is furnished with the car.

#### The Bridgeford Bevel Gear Turning Lathe.

The accompanying photo illustrates the latest product of the Bridgeford Machine Tool Works, Rochester, N. Y., a lathe for turning bevel gears. This machine has been designed especially for turning simultaneously the face, front and back angles of bevel pinions and gears up to 18 inches diameter, although the first operation, consisting of boring and facing the back, may also be handled advantageously.

The frame, oil pan and reservoir are in one piece. The head stock is of simi-

GREAT WESTERN "THIRTY."

lar design to those used on the company's heavy duty geared head engine lathes. The drive is through a constant speed pulley, 15 inches in diameter, for a 6 inch belt, running at 440 revolutions per minute, and there are twelve spindle speeds, ranging from 5.8 to 214 revolutions per minute. This gives sufficient pulling power to enable three cutting tools to be used up to the limit. All gears within the head are steel and run in oil, and the bearings are self oiling.

The carriage has a travel of 13 inches and is provided with two cross slides carrying angle turning rests, the right hand one having a turret tool holder. The carriage, cross slides and angle rests have power feed and automatic stops, and hand wheels are arranged as shown, within easy reach of the operator for operating the angle rests.

The feed box gives ten ratios of feed ranging from .005 inch to .190 inch per revolution of spindle. The gears are steel and run in oil.

For the first operation the blank is chucked in a universal chuck, bored with a tool in the left hand rest, while the facing is done by tools held in the turret of the right hand rest.

For the second operation the blank is either chucked on a special hub or an arbor in the taper spindle hole, having a split bushing, the left hand turning rest carrying a roughing and a finishing tool for the face angle and the turret of the right hand rest a set of roughing and finishing tools for the front and back angles.

Two of these machines are already in operation in the plant of a well known gear manufacturer, and are said to have shown a great saving in time over engine lathe and turret lathe methods, as well as producing much more accurate work than can be done with forming tools. The total weight of the machine is 7,300 pounds net.

#### The Ronson Wrench.

Cryder & Co., Park avenue and Sixtythird street, New York city, have placed on the market a combination wrench under the above name. It comprises nine distinct wrenches, ranging in size from 18 to 16 inch. The over-all length is 6 inches. and the weight of the tool is only 8 ounces. Each of the four members shown in the illustration is said to be made of flawless plate steel, heat treated. The centre bolt and wing nut are drop forged, and when one of the ends is pulled out for use the rest form a handle which gives a great leverage. The wing nut bolt has a squared shank, making it impossible for the members to turn. The wrench is finished in nickel. The thinness of the members is an advantage in itself, as the wrench can

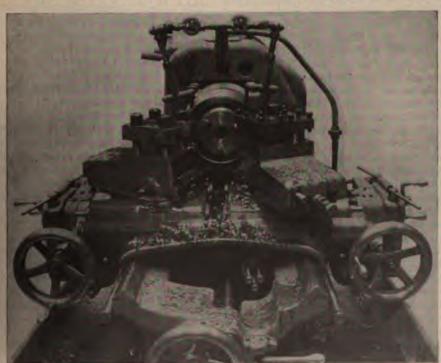

THE RONSON WRENCH.

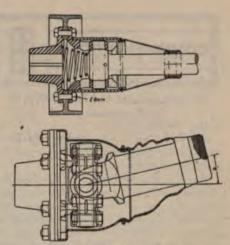

be used in places where no other wrench could be applied. This thinness, of course, requires material of great tensile strength. It is stated that the tool can easily be carried in the pocket without inconvenience.

#### Hartford Universal Joints.

The Hartford Auto Parts Company, of Hartford, Conn., are manufacturing universal joints of two different types in many different sizes and combinations. The first of the two types may be designated as the

BRIDGEFORD BEVEL GEAR LATHE.

HARTFORD UNIVERSAL JOINTS.

split ring type. In this the shafts to be joined are provided at their ends with forks with radially extending bearing pins, which have bearings in a split ring, the two halves of the ring being held together by bolts. The other type is that in which one of the shafts is provided at its end with radially extending bearing pins which have a bearing in sliding blocks adapted to slide in slots in a hollow, hub-shaped extension of the other shaft. The company makes universal joints in various sizes suitable for transmitting 20 to 60 horse power. All of the joints are thoroughly enclosed, and may be packed with grease. The type of joint comprising a sliding block is provided with a coiled spring at the end of the propeller shaft so as to take up all slack and prevent rattling. Some of the joints are assembled together with a brake drum and are designed for being secured to the rear end of the transmission shaft. Complete rear drives are furnished, comprising two universal points and a connecting propeller shaft of any desired length. A feature of these drives is that the shafts are made in one with one member of each universal joint, thus saving the extra weight of the hubs that would be required if the universal joint members were keyed to the shaft. Double universal joints with short length shafts for insertion between the clutch and transmission are also furnished. In these a coiled spring is also provided for taking up slack and preventing rattling. In one type of these double joints a leather boot extends from the housing of one joint to the other. The Hartford Auto Parts Company have recently issued a catalogue containing drawings and dimension tables of all of the different types of joints manufactured by them.

#### Another Motordrome Project.

The Monetary Realty Company has recently been organized in New York to handle a 6,000 acre tract of reclaimed New Jersey land near Hackensack. Among the incorporators of the company are P. S. Parich, Chas. Fish, Wilbur Fisk, Wm. G. McAdoo, Geo. Robertson, W. A. Post and Harold R. Gillette. It is said to be planned to construct a 3 mile automobile track.

### COMMUNICATIONS

## A Commercial Vehicle Driver's Experience.

Editor Horseless Age:

The following is a bit of my experience as chauffeur on a truck that may be of interest to your reader:

When I was introduced to my job, the machine, as left by my predecessor, was more like the proverbial scrap pile than anything else-most of it in one corner of a stable. It had been wrecked by one of the counterweights parting company with the crank shaft, a two throw with pins on the same side. The firm readily secured all replacements as required, for the truck had been purchased under some form of main-One of the curious tenance contract. things I early discovered was in connection with the mechanical oiler. It had five leads, and was operated from the cam shaft in the wrong direction by an irreversible ball ratchet. I reversed the position of the five ecentrics and the operating shaft, which, by the way, is no small job.

For the benefit of thise readers who are not familiar with this oiler, I will explain the peculiarity of these eccentrics. They are each in two parts, and are set in a plane not at right angles to the shaft. In other words they "wabble." This causes a slight rotation of the plungers, which properly open and close the oil ports, and for a given setting the running direction is all important. From inquiries I made I found that this oiler was part of the original equipment that had been in use two years. There was evidence that it had been tinkered with, and I suppose some driver had had the temerity to take it apart. It is almost inconceivable that he would have gotten the combination together again, not in part, but in an entirely reversed order.

This would seem to suggest an inusual oil economy. But such was not the case. I found in the basement two barrels containing a light and heavy grade of machine oil. I was informed that the practice was to mix the two grades together as needed, and every morning before starting out pour a "fire pail" full of it over everything in sight in the crank case. A word about this case. The engine was horizontal. The case contained everything from where the cylinders bolted on up to and including the differential on the rear axle. It was an all spur gear drive with the lowest point under the differential, where the case was partly formed by thin sheet steel secured to side castings by button head screws. This was anything but an oil tight arrangement.

For two-thirds of the time the most persistent annoyance was caused by the failure of proper lubrication. It was some fime before I got the management to supply a good gas engine oil, and I had trouble with leaking oil pipes. After trying flexible

metallic tubing without success, I adopted a one-eighth inch gas pipe, making it up with plenty of elbows and unions. This gave the best satisfaction. M. F. BATES.

## Cause of Peculiar Motor Action. Editor Horseless Age:

I have a new four cylinder, 30 horse power car, and I would like to know what is the cause and remedy of the following trouble:

Often when I switch off the magneto or batteries to allow the engine to stop, and the motor is just stopped, a spitting noise occurs in the carburetor and the engine runs backward a number of revolutions with a horrible knocking. To start again it requires quite a good deal of cranking. When this backing does not occur the motor starts on the push button. The motor runs fine and develops fine power.

A. STEGNER.

[If the motor runs backward a couple of revolutions it is a sign that an explosion occurred in the cylinder when the motor had stopped or almost stopped. That the motor turns the reverse way is due to the fact that ignition occurs before the crank comes to the dead centre position. Very likely the charge is ignited by incandescent carbon on the cylinder walls. It is also

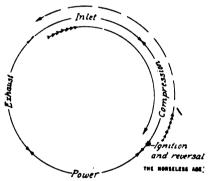

DIAGRAM OF CYCLE OPERATIONS.

possible that some part protruding into the cylinder gets so hot as to cause ignition of the charge. The swishing noise in the carburetor is explained as follows: Ordinarily the four strokes of the cycle are as follows:

Down stroke. Inlet. Inlet valve open Up stroke. Compression. All valves closed Down stroke. Power. All valves closed Up stroke. Exhaust. Exhaust valve open

Suppose that the ignition current has been turned off and the motor has almost come to rest. While nearing the end of the first up stroke or compression stroke the charge is automatically fired and the rotation of the engine is thereby reversed. (See accompanying sketch.) The valve functions then follow each other in the reverse order, and each stroke is reversed; that is, the piston moves up while the inlet valve is open and down while the exhaust valve is open. The force of the explosion toward the end-of the compression stroke forces the piston down. During the next

up stroke the inlet valve is open, and the engine therefore exhausts through the carburetor. This explains the swishing noise in the carburetor. During the next down stroke the exhaust valve is open and the engine draws in a charge of burnt gases from the muffler. This explains why it must be cranked for some time after it has stopped in the above described manner before it can be started again.

In order to remedy the trouble you should thoroughly clean your combustion chamber and piston head walls of carbon and see to it that the water circulates properly and keeps the engine cool.—[5,6]

#### Queries From a User.

Editor Horseless Age:

I would be pleadsed to have a few questions regarding ignition, etc., answered in your columns:

- I. Why is it that vibrators are not required on some coils?
- 2. Explain how a spark of the proper thickness and heat is produced by a non-vibrator coil.
- 3. Which is better, a four unit coil or single unit coil and distributor?
- 4. Number the four cylinders of a car, beginning in front. That is, which is 1, 2, 3, 4?
- 5. Does a sliding gear grow quieter with usage, as some operators claim, or more noisy?

  A. C. K., M. D.

[If the timer contacts are of such construction as to produce a quick, sharp break of the circuit, this will cause a sudden interruption of the current flow in the primary winding of the coil, which will cause a strong current impulse to be induced in the secondary, and thus a spark produced. Nonvibrator coils are usually used in connection with special contact devices or timers. There is this difference between the action of a vibrator coil system and a system comprising a plain or non-vibrating coil, that whereas with the former the spark in the cylinder occurs a certain fixed time after the contact in the timer is made, with the latter a spark occurs a certain fixed time after the contact in the timer is broken

The spark is produced in the non-vibrator coil in exactly the same way as in the vibrator coil, viz., the dying down of the current in the primary winding (due to the breaking of the circuit at the vibrator in the one case and in the timer in the other case) has an inductive effect on the secondary winding of the coil. What is most essential to a strong induction in the secondary winding of the coil is a quick cessation of the current in the primary winding. This is brought about by the condenser, which is connected across the vibrator in a vibrator coil system and across the interrupter or timer in a non-vibrator coil system.

Whether a four unit coil or a single unit coil and distributor is better depends largely upon the qualities of the distributor. In earlier years the multiple unit coils were generally used, because it was then found exceedingly difficult to insulate high tension distributors so well as to make them reliable under all weather conditions. You will understand that the problem of insulating currents of such high voltage as to jump threequarter inch gaps in the atmosphere is a very difficult one, but it has now been satisfactorily solved. With a first class high tension distributor we should prefer the single coil and distributor system, because it is less expensive in the first place, and there are fewer parts to be kept in adjustment. The very fact that high tension distributors are used on all high tension magnetos shows that it is now possible to make these distributors so as to work reliably.

If we wanted to number the cylinders of a four cylinder, conventional type vehicle, we would call the most forward one No. 1, the following one No. 2, the following one No. 3, and the most rearward one No. 4. The cylinders may then fire in one of the two following orders, viz., 1, 2, 4, 3 and 1, 3, 4, 2.

The sliding gear may grow either quieter or more noisy with use. If the teeth should not have been cut perfectly it is conceivable that they will wear in with use and mesh more perfectly after the car has been in operation for some time. However, if the gears were cut perfectly in the first place, the gear will most likely grow noister as it grows older, owing to the fact that after the teeth are worn below their normal thickness they will not mesh so perfectly, and as the bearings become worn it becomes possible for the gears to shatter in operation.—En.]

#### Ignition Wiring.

Editor Horseless Age:

I have been a reader of your paper for more than four years, and never asked a question before. I would be pleased to have you give me wiring diagrams for a four cylinder, two cycle engine (a) when a magneto and a battery are used (the battery for easy starting) and (b) when a magneto is used only. How do you switch over from the battery to the magneto?

J. G. Allen.
[In a four cylinder, two cycle engine
there are four explosions during each revo-

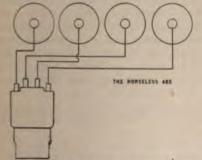

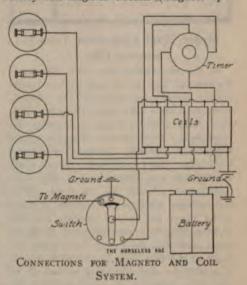

DIAGRAM OF MAGNETO CONNECTIONS.

lution of the crank shaft, consequently the explosions follow each other at intervals corresponding to one-quarter crank shaft revolution, or one-half piston stroke. This necessitates placing the cranks on the quarter. The cranks may be arranged in different ways, but in some four cylinder, two cycle cars on the market they are arranged so the cylinders fire in the order 1, 3, 2, 4. This means that cranks 1 and 2 are opposite or at 180 degrees with each other, and cranks 3 and 4 the same.

The wiring for the magneto alone is extremely simple. Simply connect the four high tension terminals of the magneto to the four spark plugs, making sure to connect the proper terminal to the proper plug. This can be done by noting that when the rotating arm of the high tension distributor of the mageto makes contact with one of the terminals the piston in the cylinder to which this terminal is connected must be near the top of the stroke. Presuming that the cylinders fire in the order 1, 3, 2, 4, the connections are made as shown in the accompanying sketch. The magneto has also one primary binding post from which a wire is brought to a switch on the dash or steering wheel. By means of this switch the primary winding of the armature is short circuited when it is desired to cut out ignition. One terminal of the switch is grounded and the other connected to the primary terminal on the magneto.

You also want to know the method of connection when a battery is used in connection with the magneto for easy starting, and in your sketch you show a Bosch DR4 magneto. We presume that you have one of the latter magnetos, but that it is not made specially for "dual" ignition. In order to use batteries in connection with the magneto you require the following extra parts: A non-vibrator coil for the battery; a contact breaker for the battery and a switch for switching over from the battery to the magneto, and vice versa. The magneto requires certain alterations to adapt it to use in connection with batteries. A double circuit breaker must be fitted in place of the single circuit breaker, and the high tension distributor must also be altered. The Bosch Magneto Company also make a special combined switch and coil, and as these are specially designed for use with their magneto, you will probably be best advised to get these parts from them. They also issue a booklet giving a diagram of connections.

If you have room for two sets of spark plugs in your engine (you might, of course, screw the spark plugs into T fittings screwed into the spark plug holes in the cylinders), you can use two entirely separate systems of ignition, and this may be advantageous if you already have a coil equipment and want to use that. In that case the magneto is connected to its plugs exactly as though it alone were used. The battery system, supposing that you are using four vibrator coils, could be arranged as shown in Fig. 2. As regards timing, it might be advantageous to have the magneto spark occur at a fixed time and only connect the battery timer to the spark lever. You would have to use a combination switch which in one extreme position would establish the battery circuit and ground the magneto armature (battery operation), in the other extreme position open both the battery and magneto circuits (magneto op-

eration), and in the mid-position open the battery circuit and ground the magneto circuit (stopping),—En.]

#### Importance of Carburetor Throttling Resistance.

Editor Horseless Age:

Referring to the article on "Calibrated Carburetors," by Frank H. Ball and Fred O. Ball, in your August 4 number, will you not kindly explain in an early number the significance of "the throttling resistance at full power," and why it is important to have this as low as possible?

G. H. T.

[When operating at full power it is important to get as much charge as possible into the cylinder during each suction stroke, The maximum charge is evidently equal to the displacement volume of the piston filled to atmospheric pressure. When the engine is pulled down in speed by a heavy load while running with the throttle fully open nearly this amount of charge may be taken into the cylinder, but at the comparatively high speed at which the engine delivers its maximum power there will be a considerable reduction in the quantity of this charge, owing to the resistance of the inlet pipe and carburetor passage. This reduction in charge, which it is desirable to keep as small as possible, increases with the length of the inlet passage and with the speed of revolution of the engine and decreases with the cross sectional area of the inlet passage. The throttling resistance is a measure of this reduction of the charge.

The Xargil Manufacturing Company, of Utica, N. Y., on October 1 will move into their new plant, a three story brick building at 34-38 Broadway, formerly occupied by the Eureka Mower Works. In the new plant the company will have sufficient capacity for turning out 200,000 mufflers a year.

# Commercial Applications.

# Motor Mail Collection Trial in Kansas City.

At the request of the First Assistant Postmaster General a test of the motor car as a collector of mail was recently made in Kansas City, Kan., the automobile used being a 28 horse power Franklin, offered by L. A. Robertson, manager of the Franklin Automobile Company, of Kansas City, Mo. Two collection routes, along which were 150 letter boxes widely scat-tered, were selected for the trial. With the ordinary methods of collection it takes seven hours and twenty minutes for two men and two horses to cover this combined route, and with the motor car a start was made at the City Hall at 5 o'clock, and at 7:40 o'clock, after the lapse of two hours and forty minutes, the collector had returned to the post office for the last time. The distance covered was approximately 35 miles, and a stop was made at each of the 150 boxes. This saving of four hours and twenty-five minutes in the collection of mail on the two routes was made in a test conducted by H. J. McKinnon, city superintendent of carriers.

# Motor Ambulance for Harrisburg, Pa.

We illustrate herewith the motor patrol and ambulance recently placed in service by the city of Harrisburg, Pa., replacing its former horse equipment. The vehicle was built especially for the purpose by Thos. B. Jeffery & Co., of Kenosha, Wis., and contains a larger frame, heavier axles, heavier springs and larger wheels and hubs than the standard Rambler cars. It has a four cylinder, 45 horse power motor, 123 inch wheel base and 35x5 inch tires. The interior is so arranged that it is possible to accommodate four injured people at one time,

as well as several attendants. The equipment consists of three stretchers, two of which are for ordinary work and one stair stretcher which can be used in carrying a patient around a winding stairs without any danger of jarring. The inside is finished in birdseye maple and hardwood, so that the body can be scrubbed and kept perfectly sanitary and clean. A large electric dome supplies illumination.

# Commercial Notes.

The Autocar Company has contracted for fifteen more cabs to be delivered to the Baltimore Taxicab Company early in October.

A motor bus service has been inaugurated between Washington and Marianna, Pa. A twelve passenger machine is used, and one round trip is made per day.

A McIntyre light delivery truck, equipped with a special refrigerator body, has been purchased by Dogan & Deffry, proprietors of a large meat market at Kenosha, Wis. It will be placed in use October 15.

The Long Beach (Cal.) Transfer Company has recently placed in service a rapid motor truck of 4,000 pounds load capacity, for service between Los Angeles and Long Beach. The truck is built with a four cylinder, 35 horse power motor, and makes the trip between the centre of Los Angeles to Long Beach in two and one-half hours with load.

The Berks Auto Transit Company, of Reading, Pa., have established an automobile service between that city and Millersburg, a distance of 25 miles. The company have been operating a service between Reading and Bernville for some time, and have now extended the line 11 miles to Millersburg, through Strausstown, Rehrersburg and Schaefferstown.

A sightseeing company is planning to run motor buses in Rock Creek Park, D. C., and has applied for a permit to the commissioners. The type of buses which it was at first proposed to place in service were considered too heavy by the engineer department, and Commissioner Judson is

at present making inquiries in New York and Philadelphia with regard to the type of vehicles in service in Central and Fairmount parks.

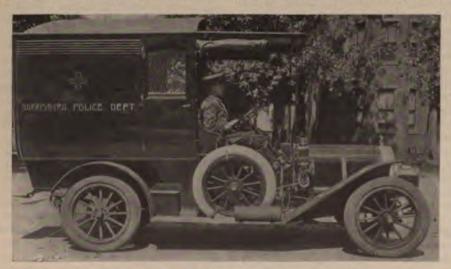

# Parts Exhibitors at Atlanta Show.

For the Atlanta Automobile Show, which opens November 6, forty members of the Motor and Accessory Manufacturers' Association have taken space. The allotment of space to them was completed at headquarters, on September 22, by the show committee of the M. and A. M. Following is a list of those that have taken space: Ajax-Grieb Rubber Company, Badger Brass Manufacturing Company. S. F. Bowser & Company. Byrne, Kingston & Company Connecticut Telephone and Electric Company. Diamond Rubber Company. Joseph Dixon Crucible Company, Dow Tire Company. Electric Storage Battery Company. Empire Tire Company. Federal Rubber Company. Firestone Tire and Rubber Company, The Fisk Rubber Company. G & J Tire Company.

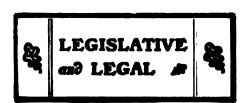

B. F. Goodrich Company Gabriel Horn Manufacturing Company. Goodyear Tire and Rubber Company. A. W. Harris Oil Company. Hartford Rubber Works Company. Herz & Company. Kokomo Electric Company. Jones Speedometer Company. Leather Tire Goods Company. C. A. Metzger, Michelin Tire Company. Morgan & Wright. National Carbon Company. Never-Miss Spark Plug Company. New York and New Jersey Lubricant Company. Oliver Manufacturing Company. Randall-Faichney Company. Republic Rubber Company. C. A. Shaler Company. Stromberg Motor Devices Company. High Wheel Auto Parts Company. C. F. Splitdorf, Sprague Umbrella Company. Veeder Manufacturing Company. Weed China Tire Grip Company. Hartford Suspension Company.

# To Test Taximeters in Massachusetts.

As numerous complaints have been made about the inaccuracy of taximeters in use in Massachusetts, D. C. V. Palmer, State Commissioner of Weights and Measures, has taken the matter under advisement, with a view to formulating some plan for their inspection and testing. Mr. Palmer recently returned to Boston from New York, where he looked into the matter from various points of view. While as yet nothing definite has been decided upon, the tests will probably be of a practical nature, rather than so-called bench tests. For this purpose it is planned to lay down an accurately measured course in each of the principal cities, I mile in length, this mile being divided into fourths and sixths, the units employed in the most used taximeter tariffs. This course is to be marked by bronze plates set in the curbstones and suitably inscribed.

RAMBLER PATROL AND AMBULANCE NOW IN DAILY SERVICE AT HARRISBURG, PA.

# Chicago Public Vehicle Drivers' Licensing Ordinance.

An ordinance has been introduced in the Chicago city council requiring all applicants for automobile drivers' licenses to pass a rigid physical examination before a board of automobile registry, which is to be composed of the city electrician, the health commissioner and the city engineer. The applicants must have the free and full use of their arms and legs, and be more than eighteen years old; must have good eyesight, and if they wear glasses the latter must hook over their ears; must have good hearing, be free from heart disease and fainting fits, and not addicted to the use of alcoholic liquors or injurious drugs; be able to guide machines through crowded streets. to turn suddenly and to quickly handle the machine in emergencies. Amendments have been suggested which require the reporting of every accident to the board of registry, and reports from garages of the names of the chauffeurs operating their machines during the day. Applicants who satisfactorily pass the examination, pay the examination fee of \$3 fixed by the ordinance and furnish a bond will be given a license. If the new ordinance should be passed it would apply to drivers of public vehicles only, as the State automobile law deprives the city authorities of the right to license private drivers.

# Another Spark Plug Patent Suit.

Joseph H. Lehman, of the J. H. Lehman Manufacturing Company, 29 West Fortysecond street. New York city, has filed an application for an injunction against A. R. Mosler & Co., 163 West Twenty-ninth street, New York, for alleged infringement of United States patent No. 741,684, which was issued to Mr. Lehman on October 20, 1903, on an application filed February 6. 1902. A. R. Mosler & Co. state that they are advised by their counsel that the above patent is not infringed by the manufacture, sale or use of any of their spark plugs, and they are willing to defend at their expense any party against whom suit may be brought under the above patent by reason of the sale or use of their spark plugs.

# Indianapolis Street Traffic Regula-

An ordinance has been introduced in the Indianapolis city council to regulate street traffic in what is known as the mile square, or retail business district of the city. It provides that vehicles of any description shall not stand within the mile square in such a manner as to prevent the free passage of pedestrians or vehicles. This is designed to stop the practice of vehicles standing two

abreast in the business streets. The police have also recently adopted a schedule of traffic rules for the streets.

# Milwaukee's Congested District Ordinance May Be Modified.

It is likely that the rule recently adopted by the Milwaukee (Wis.) common council to prohibit the use of Grand avenue and Wisconsin street, main thoroughfares, by automobiles and other vehicles for a longer period than necessary to discharge passengers or permit them to enter, will be modified. There is apparently no object in such restrictions during the hours from 9 o'clock in the evening until 5 o'clock in the morning, when traffic is light and danger of congestion is past.

### Ohio Supreme Court Against Municipal Auto Tax.

By a decision handed down by the Ohio Supreme Court in the case of Colter, a tax-payer, against the city of Cincinnati, it is declared unconstitutional for any municipality to enact an ordinance providing for licensing motor cars. That authority is wholly vested in the State, according to the decision. The case was appealed from the lower courts, in which it was decided in favor of the city. The decision followed that given in the case of Frisbie vs. City of Columbus, which was the test case. The decision will save autoists thousands of dollars.

# Municipality Defies State Legislature.

Although the municipal court at Stevens Point, Wis., recently decided that State laws limiting the speed of automobiles in cities to 12 miles an hour and in the country to 25 miles an hour supersede all municipal ordinances, the city of Plymouth, Wis., has passed an ordinance with a speed limit of 8 miles an hour.

The board of governors of the St. Louis Automobile Manufacturers' and Dealers' Association at a recent meeting indorsed a traffic regulation ordinance drawn up by S. D. Capin, president of the St. Louis A. C., which has been introduced in the City Council.

# Six Day Motorcycle Race Stopped Early.

A six day motorcycle contest organized by the Motorcycle Contest Association of New York, started on the Brighton Beach track, on Long Island, at 12:01 o'clock on Monday morning. Five teams took part, known respectively as the Harlem Motorcycle Club team, the New York Motorcycle Club team, the Bedford Park Motorcycle Club team, the Brooklyn team and the Flatbush team. Very fast time was made on the first day, but the race was called off on the second day owing to the continuous rain, which made the track slippery and dangerous. The attendance on the first day was small.

# Mr. Couzens' European Impressions.

James Couzens, secretary and treasurer of the Ford Motor Company, with Mrs. Couzens, returned on the steamer Coronia September 21, after a six weeks' trip to England, France, Germany and Switzerland. He says that American cars to be sold on the other side will have to be pushed in energetic fashion, for the trade outlook there isn't nearly as encouraging as it is in this country now.

"No American maker should look for foreign trade with the idea that it is going to be obtained easily," said Mr. Couzens. "While one always likes to take an optimistic view, I don't like to say that there is going to be a rush for our American cars over there when such a statement would be deceiving.

"There is an opportunity abroad to sell a great many American cars, and the number to be sold will constantly increase. In order to obtain the business, however, conditions over there must be carefully considered, and trade cared for in European fashion. We have sold 115 cars in France this year, which far exceeds anything accomplished by any other American company. Our agent, Henry De Passe, has ordered 300 cars for 1910. The French expect a great deal from the Darracq Company, which is making a 20 horse power, four cylinder car to sell at \$1,000. You know the Ford over there sells at \$1,200. The French makers are looking for an increase in their tariff as a protection for their industry.

"In London we have established a branch at 55-59 Shrewsbury avenue. The Ford is in great favor among Englishmen, and we look for a large increase in our trade there next year.

"I combined a little pleasure with my business trip, doing some touring in the Ford car through the Château country in France. Automobiling over there on the magnificent roads is certainly a luxury, and I can well understand why everyone talks of touring Europe. The scenery, the roads, the accommodations are all excellent.

"Automobile trade conditions on the other side are getting better, although they have had no such year as we have had in America. The recovery in the motor car trade has been slow, whereas here we have not noticed the slightest kind of a falling off, but, on the contrary, the demand seems to be increasing."

# A. O. Smith Company Increases Capital.

The A. O. Smith Company, of Milwaukee, Wis., one of the largest manufacturers in the world of pressed steel automobile frames and parts, has increased its capitalization from \$500,000 to \$1,200,000. The additional issue is to cover the new \$500,000 plant that is being erected on Keefe avenue, between Twenty-seventh and Thirtieth streets, Milwaukee.

# GARAGE ITEMS

#### A Tent or Portable Garage. By H. H. Brown.

It often happens that the owner of an automobile may wish to have the same near at hand in some more or less isolated place where no garage, barn or other shelter is available, as at a camp of a more or less temporary character. A simple but ingenious idea, which was devised by an automobilist of Chicopee Falls, Mass., for housing a large touring car while wintering in Florida, furnishes a rather good solution of the problem. It consists in using an ordinary wall tent, which in this particular case is 18x18 feet. A spike similar to that in the tent poles is driven into the front end of the ridge pole, and this fits into two holes in a pair of diagonal poles or shears. These are reinforced where the pin passes through with galvanized sheet iron. In this simple manner the whole front of the tent can be opened for the passage of the machine. The ends of the diagonal poles are braced against tent pegs. It can readily be seen that this idea may be applied to almost any sized tent which may be available for the purpose and which is large enough to accommodate the machine to be housed.

# New Indianapolis Garage.

A new garage has recently been opened on North Illinois and Twenty-second streets, Indianapolis, Ind., which is known as the "Twenty-second Street Garage." The business is conducted by A. L. Duggan, manager, and C. W. Allison. This is quite an imposing structure, the outside being of terra cotta, with three large show windows facing Illinois street and one large one facing Twenty-second street. The north or Twenty-second street side is one uninter-

rupted line of glass, but the sash are placed well above the ground, making it very light inside but shutting out the public view.

There are two entrances, both on Twenty-second street, one at the front and one at the extreme rear. Every convenience for the storage and care of cars is being installed. A Bowser gasoline pump is located at the left of the rear entrance, and next to this are the tanks containing the several grades of oil. A card system for tagging the supplies and repairs will later be introduced with a view of making every appointment up to date. The main building is 50x150 feet. It is veneered on the inside with one course of brick, while the outside is, as before stated, of terra cotta. The floor of the entire lower story is cemented and the building has a flat roof overhead. The office is located in the front, facing Illinois street. A building to contain repair shop, the heating plant and vulcanizing room is being erected at the rear. It is 36x40 feet and two stories high, of the same construction as the main building.

Electric power will be used in the shop and for charging batteries.

# Premier Agents' Convention.

The annual meeting of agents of the Premier Motor Manufacturing Company was held in Indianapolis last week, thirtytwo agents attending from all parts of the country. It continued three days, including a run to French Lick to demonstrate the running ability of the company's 1010 models. On Tuesday the agents visited the factory and listened to talks on the construction of the 1910 cars. In the evening a banquet was given at the Denison Hotel. Those who were on the program to speak were President H. O. Smith, Mayor Charles A. Bookwalter, Henry Eitel, president of the Indiana National Bank; P. J. Stocker, who spoke on advertising; R. I. Eades, Webb Jay and Charles Davis, field men for the company; John B. Oram, advertising manager and R. W. Macy, sales manager. The run to French Lick and return was without special incident. After returning Thursday afternoon a trip was made to the Indianapolis Motor Speedway, a dimer was given at the Country Club and the meeting closed with a theatre party

# Motor Manufacturing Company Organized in Hartford, Conn.

The Parker Motor Company has been organized at Hartford, Conn., with an authorized capital of \$50,000, to manufacture automobile motors, primarily for the McCar Company, of Hartford, who manufacture the McCue car. L. D. Parker, one of the directors of the McCue Company, is president and treasurer of the new company; C. T. McCue, president of the McCue Company, is vice president, and F. C. Billings, vice president of the McCue Company, is secretary of the Parker Motor Company. The new company will occupy the plant of the Springfield Elevator and Pump Company on Windsor street. It is planned to build a four cylinder, four cycle engine with valves on opposite sides. A production of 3,000 engines is planned for the first year. Special machinery is now being installed, and motors will probably be turned out before the first of the year. The McCue Company will act as distributing agents for the Parker Motor Company.

# Pope Report Shows Large Earnings.

The Pope Manufacturing Company las just filed its first report since its re-organization, which covers the period from December 24 to July 31. It shows income from operations after deducting costs, expenses, depreciations, etc., of \$462.815. Other income amounted to \$58,028, bringing the total income up to \$520,844 Charges, organization expenses, etc., amounting to \$37,977 left net earnings of \$482,866. The president's report shows that the company has borrowed no money for any purpose since beginning business under the reorganization, and taken advantage of discounts for cash payments in buying material, so that the only indebtedness at the close of the year was current bills. He also emphasizes the showing made in the payment on July I of \$800,-000 notes issued at the time of the reorganization, without encroaching on the working capital.

# Another Detroit Manufacturing

Company.

The Warren Motor Car Company has been organized at Detroit with a capital stock of \$100,000 to manufacture automobiles. At the head of the company is Postmaster Homer Warren. The other incorporators include C. R. Wilson, of the Wilson Body Company; Harry N. Snyder, manufacturers' representative for Michigan for Michelin tires; R. J. Brennan, W. H. Bradford and Henry C. Walters. The firm plans to manufacture light cars.

A PORTABLE TENT GARAGE.

The Frank A. Munsey Tour.

Although it was announced that 37 cars had been officially entered for the Frank A. Munsey Reliability Run, only 25 cars started in competition from Washington, D. C. on Tuesday, September 21. These were accompanied by two non-contesting cars, four official cars and three press cars, making 34 vehicles in all. The first day's run was to Philadelphia by way of Baltimore. Fourteen of the contestants came through the first stage with perfect scores. All of the cars were lined up in parking space in City Hall square, Philadelphia, where they remained over night, while the drivers and officials stayed at the Hotel Walton, Those who made perfect scores were No. o. Maxwell; No. 26, Reo; No. 12, Pullman; No. 32, Washington; No. 37, Pullman; No. 24, Crawford; No. 11, Maryland; No. 18, Corbin; No. 13, Harmon; No. 36, Elmore; No. 13, Pullman; No. 21, American Simplex; No. 28, Renault and No. 17, Croxton-Keeton. Most of the penalties suffered by the other II cars were small, however. No. 20, Winton, was penalized 4.1 points for lateness in starting and for adjusting the carburetor before starting the motor. No. 27, Matheson, was penalized 0.4 point for tightening a hub cap. No. 7, Ford, had 1.7 points imposed upon it for carburetor adjustment and stopping of motor. No. 5, Washington, was penalized 0.2 point for repairs to a fender, and No. 31, Washington, 0.1 point for stopping of the motor. No. 15, Columbia, lost 0.1 point for adjusting the brakes. No. 16, Croxton-Keeton, was penalized 0.5 point for stopping of motor and work on same. No. 14, Spoerer, was penalized 0.3 point for oiling the clutch. No. 29, Hupmobile was penalized 0.2 point for adjusting the oiler rod. No. 1, Chalmers-Detroit, received a penalty of 0.2 point for stopping of motor and fastening up the mud pan. No. 34, Selden, was penalized 0.2 point for tightening a fan bolt and for stopping of the

During the evening a meeting of the drivers and observers was held at which the observers' cards were taken up in rotation by Manager Trego, and every observer was asked to explain in detail any remarks on the cards that were not absolutely plain.

On Wednesday morning the cars started from the Hotel Walton at 9 o'clock en route for Milford, Pa. The two pilot cars had left two hours earlier. All of the 25 cars which started in the first day's run also started on the second stage and were sent off at one minute intervals. This day's route led through a very picturesque section through Eastern Pennsylvania. The roads were in perfect condition, a rain during the night having completely laid the dust. The tourists were met at the Manhattan Inn between Allentown and Bethlehem by the Lehigh Valley Motor Club, by whom they were treated to a lunch. The cars arrived at Easton, one of the checking stations, shortly before I o'clock. This day's run was somewhat less eventful than the first day's run. No. 15, Columbia, had an accident at Allentown, Pa., skidding on a slippery street and crashing into a telegraph pole, whereby both of the front wheels were wrenched off. No one was injured, however, and it was the intention to repair the car and continue the run. The scores for the day were announced by the committee as follows: Those penalized were: Ford, 0.3 point; Washington, No. 5, 0.1 point; Washington, No. 31, 0.1 point; Pullman, No. 37, 3.6 points; Chalmers-Detroit, 1.5 point; Croxton-Keeton, No. 16, 4.3 points; American Simplex, 0.1 point.

Those making clean scores were: Maxwell, Reo; Pullman, No. 12; Crawford; Washington, No. 32; Maryland, Spoerer; Croxton-Keeton, No. 17; Winton, Marmon, Elmore; Pullman, No. 13; Matheson, Renault, Hupmobile.

On Thursday the run was continued to Albany, N. Y. All of the contestants got away from Milford on time. There were two checking stations en route, at Newburgh and Kingston, respectively. Lunch was taken at Kingston. The route led along the west bank of the Hudson. The tour reached Albany late in the afternoon and the contestants put up at the Kenmore Hotel. Mayor Snyder, of Albany, Deputy Commissioner Rice and several others welcomed them at Kenmore and escorted them to the city. Before proceeding to the hotel the participants in the run stopped at the market square, where they were received by Secretary Howard B. Martin of the Albany Automobile Club and other members of that organization.

The roads encountered during the day were quite muddy, and this in connection with the fast schedule required wrought havoc with the perfect scores, so that only six of them were left at the end of the day. Several accidents were reported. The Maryland car No. 11 was ditched a short distance out of Albany, owing, it was said, to its steering gear becoming locked. Jesse L. Cassard, an official of the tour, who was one of the occupants of the car, was thrown out, but escaped without injury. Efforts were made to get the car back onto the road, but up to a late hour they had not been successful. The Washington No. 5 also met with an accident and did not report at Albany. The same is true of the Pullman No. 37, but the occupants of both of these cars expected to have been in shape again to start on the run to Boston the next morning. The penalties incurred during the day were as follows: No. 29, Hupmobile, 0.4 point for work; No. 26, Reo, 4 points for late arrival; No. 12, Pullman, 36.7 points for work, 0.6 point for cost of material, 30 points for lateness; No. 24, Crawford, 0.4 point; No. 31, Washington, 0.2 point for work, 31 points for lateness; No. 32, Washington, 0.2 point for work, 2 points for lateness; No. 16, Croxton-Keeton, 0.9 point for work, 0.2 point for cost of material; No. 27, Matheson, I point for work, 0.1 point for cost of material, No. 15, Columbia, was penalized 382.7 points in connection with the accident the previous day, of which 25.7 points were for work, 3 for cost of material, and 354 for lateness at Milford.

Friday's run was from Albany to Boston and the last half of it was made in a drenching rain. There was only one checking point en route and that was at Worcester. The day's run ended at the Bay State A. C. on Hemenway street, and the tourists put up at the Hotel Somerset. Manager Trego decided not to examine the observers' cards on Friday night and the scores became available only Saturday, Because of the heavy rain an attempt was made to arrange to place the cars in a garage, but none was available that was large enough to accommodate them all, and the result was that they were parked at the point originally planned, to the west of the Somerset.

On Saturday the contestants made a visit to Fort Warren, enjoyed a dinner in the Relay House and in the evening returned to their hotel in Boston. 'It had been planned to stop two full days in Boston but a different plan was formulated on Sunday morning. A meeting of the contestants was called at 11 o'clock and it was decided by unanimous vote to leave early in the afternoon for Willimantic, Conn. The chief reason for this quick departure was that early Sunday morning the officials received a message from Willimantic stating that a bridge on the schedule route near that city was down, and that it would be necessary to take a ten-mile detour. It was decided to stop overnight at the Hooker House, Willimantic. This day's run was 107 miles. Some difficulty was experienced in getting all of the drivers together, but when all had finally been reached the cars were driven to the White garage on Newberry street, where gasoline and oil were taken on. From here they went directly to the Bay State Automobile club at the Hotel Carleton and were checked out. Chairman Trego's National car left at 1.28 and was followed a few minutes later by the first contesting car and at one minute intervals by the others, until the last car ready was checked out at 1.54. The start was made in a pouring rain. In the trip to Willimantic, 107 miles, a schedule based on an average speed of 18 miles per hour was laid down. All of the cars finished the run by 8 o'clock in the evening.

On Monday the run to New York was made without much difficulty, although it rained at intervals during the day. In the evening a banquet took place at the Waldorf-Astoria, attended by all of the contestants and by Frank A. Munsey, the organizer. Only one of the cars was definitely withdrawn at this stage, namely, the Selden, whose driver was urgently called to New York while the cars were up in New England.

Twenty-one cars arrived in Philadelphia on Tuesday evening after a 195 mile trip from New York via Atlantic City. Referee Trego announced there that the standing of the cars would not be announced again until after the final examination at the conclusion of the run in Washington. Six of the cars checked out from Boston Sunday afternoon with perfect scores, namely, the Maxwell, one Croxton Keeton, Marmon, Elmore, Pullman and the Renault.

# To Manufacture Cars in Richmond, Ind.

The Pilot Motor Car Company, of Richmond, Ind., have been incorporated under the laws of Indiana with \$100,000 capital. They will manufacture a 30-35 horse power four and five passenger car to sell fully equipped with top, glass front and speedometer for around \$2,000. The new firm will occupy the building formerly occupied by the Kramer Manufacturing Company, on Fort Wayne street. The building is of brick and has a very large floor space, part of it being two stories high. The incorporators are George E. Seidel, Clarence H. Kramer and Horace M. Kramer. Operations in the new location will begin in about thirty days. The experimental work is being done at present at the Seidel Buggy Company's plants.

### Twenty-four Hour Race Postponed.

The twenty-four hour race which was to have been held on the Brighton Beach track on Long Island on Friday and Saturday of last week was prohibited by the police at the last moment, owing to the dangerous condition of the track, due to two days of more or less continuous rain. The management of the race protested vigorously against the police interference, as it had been announced that the race would be held "rain or shine," but the protest was of no avail. The race may be held at some future date, possibly October 14 and 15.

### Club Notes.

An automobile club is being formed at Eau Claire, Wis. Many owners there are members of the Wisconsin State A. A., affiliated with the A. A. A., and wish to become more closely related to each other. The draft of the proposed constitution states one object to be "to extend a welcome hand to the numerous tourists and visitors who daily pass through and stop in Eau Claire."

The Texas Automobile Association has been organized with headquarters at Houston. Among the objects of the organization are to drive out the "road hog" of every. class from the highways and to furnish free legal service to members, it being the intention to engage the services of an attornev in every important city of the State. The advisory board of the association consists of Col. J. W. Munn of Galveston, M. L. Mertz of San Angelo, Edwin J. Kiest of Dallas, E. J. Palmer of Houston, Col. Sam Park of Beaumont, G. W. Hawkins of Houston, E. H. Perry of Austin, and J. W. Link of Orange. The association plans to publish a hand book containing a list of members, a reprint of the State law and other useful information.

#### No Horseless Sunday for London.

About three months ago a member of the Westminster City (London) Council made the suggestion that in order to demonstrate the great usefulness of the automobile a part of London should be blocked to the entry of horsed vehicles of every kind, and that only motor vehicles should be permitted to perambulate for twenty-four hours the streets in the selected neighborhood. A Sunday in October was selected as being a period of the year when a more effective demonstration could be made, owing to people then having returned to town from their summer vacation. The publication of the idea received considerable encouragement from the majority of the newspapers, most of them giving it enthusiastic support without troubling to inquire too deeply into the merits of the scheme.

Now, to close the square half mile of London streets to all else but motor traffic would involve a policeman being stationed at every impinging street, and no chief commissioner who valued his position would dare to brave public opinion by issuing the necessary order, however great might be the influence and interest brought to bear upon him.

But the greatest obstacle that imposed itself upon the promoters was that of finance. When the scheme was first mooted the objectors wanted to know whether passengers in horsed vehicles-private carriages, cabs, omnibuses—together with any other horsed traffic, would have to go around the area to be barred to horses. Thereupon announcement was made that motor vehicles would be provided to transfer passengers, etc., across the district, and that such vehicles could be used free of charge, the cost of them coming out of a fund to be raised for the purpose by voluntary subscription. Further, the various companies operating horsed omnibuses were to be asked to keep their vehicles away from the neighborhood for the day, substituting their motor buses on the service. It was estimated that the cost of carrying out the scheme would amount to \$5,000. But no more than about \$250 came from a few parties who had axes to grind. Sundry meetings were held, to which were invited influential persons, who studiously kept away. The final blow came from two quarters: The omnibus companies refused point blank to have their traffic arrangements upset, while the most important person concerned, viz., the commissioner of police, regretted he could not permit constables to help the scheme.

# Italian Auto Finance to Be Investigated.

A sensational suit is at present occupying the courts of Turin, Italy. The president and three of the directors of the Fiat Automobile Company have been accused of falsifying the balance sheets of the company, of repeated fraudulent transactions and of inflating the value of stocks. It may be recalled in this connection that the

shares of the Fiat Company, which have a par value of 25 lire, were at one time quoted at the Turin Bourse at 2,800 lire, and that this apparent success of the Fiat Company induced a regular automobile promotion fever, in the course of which about 200,000,000 lire are said to have been invested in Italy in automobile companies. of which only a very few made a success, so that the greater portion of this capital was lost. The Attorney General has now brought suit against the president of the company and three of the directors. Whether there is any foundation for the charges can, of course, only be determined after the trial has been concluded.

#### The Riverhead-Mattituck Race.

A race for stock cars of five classes was held on a triangular course 22.75 miles long. between Riverhead and Mattituck, L. I., N. Y., on Wednesday, September 29, under the management of W. J. Morgan. The highways over which the race was held are of loam, and it proved to be the fastest course in the country. The best showing was made in Class 4, an event for cars selling between \$1,251 and \$2,000, over a distance 113.75 miles long. This distance was covered by a Buick, driven by Louis Chevrolet, in 97m. 36 3-10s., at an average speed of 70 miles per hour, which is a record for this country. Event No. 1, for cars selling at \$4,001 and over, was won by Ralph de Palma in a Fiat. The distance was 227.5 miles, and this was covered in 218m. 35 6-10s. The winner in Class 2, for cars selling between \$3,000 and \$4,000, was won by Frank Lescault in a Palmer-Singer "Six-Sixty." Lescault covered the 182 miles in 179m. 4s., or at slightly more than 61 miles per hour. Class 3 was won by William Sharp in a Sharp-Arrow, whose time for the 136.5 miles was 129m. 2s.., corresponding to a speed of 64 miles per hour. Chevrolet, as already stated, won in Class 4, and Class 5 was won by a Maxwell driven by A. See, whose time for the QI miles was 101m. 22s., corresponding to an average of 54 miles per hour. Class 5 was for cars between \$750 and \$1,251. One fatal accident occurred during the race. An Apperson car, driven by Herbert Lytle, skidded and collided with a tree during the first lap, hurling both its occupants from their seats. The mechanic, James E. Bates, died within an hour, and Lytle is hovering between life and death at this writing.

# Automobiles and Their Tires Are Dutiable as Entireties.

The Board of United States General Appraisers in overruling protests filed by Joseph Spiero and others declines to allow automobiles and their tires to be assessed at separate rates. Collector Loeb regarded the automobiles and their tires as entireties, with duty at the rate of 45 per cent. under the tariff provision for articles composed in chief value of metal. The importers alleged that the tires should be taxed 30 per per cent, as "manufactures of rubber."

# MINOR MENTION

The Hayes Wheel Company, Jackson, Mich., are breaking ground for another two story brick building, 200x70 feet.

The American Oil Company, of Jackson, Mich., at a recent meeting of its board of directors voted to double its capacity, and also to erect a two story brick office building.

The Spalding Carriage Company, of Grinnell, Ia., will manufacture a car to be known as the Spalding. The company will erect three new buildings for its auto department.

W. K. Dodsworth, formerly manager of the Central Garage, Pasadena, Cal., has established himself as a dealer in secondhand automobiles, with offices at 300 Chamber of Commerce.

The Krit Motor Car Company, newly organized at Detroit, are planning to turn out 1,000 low priced cars designed by Kenneth Chittenden. They will occupy the old Blomstrom factory.

The E. R. Thomas Motor Company, of Buffalo, N. Y., have contracted for Truffault-Hartford shock absorbers for their 1910 output. They have been fitting these shock absorbers for several years.

The bulk of the product of the Jackson Automobile Company, Jackson, Mich., this year will consist of four cylinder cars, of which they are planning to build 5,000. About 500 two cylinders will also be turned out.

It is announced that the Des Moines, Ia., plant of the Mason-Maytag Motor Car Company will not be shut down on November I, as was reported at one time, but will be continued by the company as a body factory.

The Rushmore Dynamo Works have recently erected a large fireproof storehouse, and will soon break ground for a two story fireproof concrete extension to their machine shop, 50x200 feet, giving them 20,000 square feet of additional floor space.

The Moline Automobile Company, East Moline, Ill., have let the contract for the erection of their new four story 100x127 foot addition. The building is to cost approximately \$40,000 and is to be ready for occupancy December 1.

The Rogers Automobile Company is being organized at Omaha, Neb., by Ralph Rogers and C. A. Overholt, of Chicago, Ill., with a capital stock of \$250,000. A factory site has been selected near the Ralston car shops. Mr. Rogers has been building cars in Chicago in a small way for some time.

The Stewart & Clark Manufacturing Company have leased for three years the quarters occupied by the Cadillac Automobile Company of Chicago, 1312 Michigan Avenue, and will take possession December I. The new quarters will provide a great convenience for city trade, as it will permit taking care of city orders promptly, avoiding the delays of handling the order through the factory.

John Clark, a garage man of Anderson, Ind., has secured a bonus from Shelbyville, Ind., and will locate a factory there for the manufacture of automobiles. Associated with him is Arthur Woodward, of Lapel, Ind.

The United States Motor Truck Company, recently incorporated under Ohio laws, plans to manufacture motor trucks in Cincinnati, and is now looking for a location. Trucks of one, two and three tons capacity are to be built.

Professor J. J. Montgomery, of Santa Clara College, San Francisco, is reported to have invented an alternating current rectifier applicable to charging automobile batteries. It is of the mechanical type, but no description is yet available.

The McFarlan Motor Car Company, of Connersville, Ind., plan to turn out a six cylinder car at about \$2,100. They will use a Brownell six cylinder power unit and Weston-Mott axles. The car will be equipped with four and five passenger bodies.

The dates for the Flag to Flag endurance contest from Denver to Mexico City have been fixed. The run will start from Denver on Monday, November 22, and will end in Mexico City the week of December 13. The finish in Mexico is to be followed by an exhibition there.

The International Harvester Company announces that the former plant of the Buckeye Mower and Reaper Company at Akron, Ohio, will be turned into a factory for motor cars. The cars will be of the buggy type. It is expected to turn out 30.000 the coming season.

Officers of the Rohrbacher Auto Power Tire Pump Company, of Blaine, Wash., were in Portland, Ore., recently in an endeavor to secure inducements for locating a factory there. The company manufacture power operated pumps for inflating tires, and H. E. Wells is the Oregon representative.

The Smith Auto Company, of Topeka, Kan., are planning to erect an assembling plant in Kansas City. The parts are to be manufactured in the Topeka plant, shipped to Kansas City and assembled there. This leads to a saving in transportation expenses, as parts can be shipped much cheaper than assembled cars.

The Fairfield Automobile Company of Baltimore, Ohio, whose incorporation we announced in a recent issue, have secured a brick building between Baltimore and Bayville, in which they will conduct a garage and repair shop. The company plan to work out several recent inventions and eventually to engage in manufacturing.

The Oakland Motor Car Company of Pontiac, Mich., have filed notice of an increase of capital stock from \$300,000 to \$800,000. It is also reported that the company have purchased four parcels of land north of the Pontiac, Oxford & Northern

tracks, measuring together 400x150 feet. It is not the intention to build immediately, but additions may be erected on the newly acquired property next year.

At a meeting of the Long Island A. C. at the club house in Brooklyn on September 29, a demonstration will be made in the garage of the practical working of demountable and detachable rims.

The Dodge Motor Vehicle Company, Irvington street, Boston, are compiling a booklet containing a complete list of the public charging stations in the cities and towns within a radius of 50 miles of Boston.

The Rainier Motor Truck Company has been organized in New York and will handle the trucks built by the Reliance Motor Truck Company of Owosso, Mich. The new company will offer purchasers a maintenance guarantee covering the operation and repair of the trucks for a number of years at a fixed yearly figure.

The Auto Specialty Manufacturing Company have started in business at 215-217 E. Ohio street, Indianapolis, Ind. They make a specialty of repairing leaky radiators, broken lamps, fenders, etc., and are also equipped for doing all kinds of machine work. The company manufacture a complete line of baby tonneaus, rumble seats, fenders and tool and battery boxes.

The Cuyahoga Motor Car Company, of Cleveland, Ohio, have sold out their gare je business and will confine themselves in the future to the manufacture of their storage batteries and electric vehicles. They have changed their name to the Cleveland Electric Vehicle Company. Quarters have been secured in the Standard Automobile Company's building on Huron street.

The New York Automobile Trade Association has postponed its Three-Day-Around Long Island tour which was to have taken place September 28-30. The A. A. A. refused their sanction for the event, because various stipulations embodied in the rules of the association were not included in the rules of the contest. The rules will probably be modified and the event set for a future date.

Articles of association have been filed by the Metzger Motor Car Company, Detroit, Mich., according to which \$250,000 of the \$300,000 capital is paid in in cash and \$50,000 is represented by the model and plans of a new four cycle, four cylinder car. Wm. E. Kelly, the designer of the car, holds 2,666 shares of stock, and the rest is held in equal shares by Byron F. Everitt and Wm. E. Metzger.

The Pierce-Arrow cars the coming season will be equipped with distinctively shaped lamps. The head lamps will all be of octagonal form, thus differing materially in shape from the usual round head lamps. On all open cars the side lamps will be square, while on the closed cars they will also be octagonal, with glass sides and front. These designs are due to the Pierce Company's art department. The side lamps are wired for the use of incandescent lamps, if the purchaser so desires.

Garage Notes.

Moses Gullusian, of Newton, Mass., will erect a \$65,000 garage in Lansdowne street, Cambridge, near Green street.

E. F. Sanford, Merced, Cal., has opened a garage in a new building on Main street, and will also conduct a repair shop.

Frank Sampson, Hollister, Cal., has bought the Loag Garage on Fourth street, together with the equipment, and will conduct a motor livery business.

H. J. Williams, Ashtabula, Ohio, has purchased an interest in the Auto Shop Co., of that city, and will have charge of the mechanical department of the firm.

The Cox Automobile Co., agents for Stoddard-Dayton and Herreshoff cars at Harrisburg, Pa., have moved into their new salesroom at 23 South Fourth street.

R. A. Fuller, of Sturgeon Bay, Wis., and Ed. Bellman, of Milwaukee, Wis., have bought the garage of Albert Wegmann. 108 Second street. Watertown, Wis.

The South End Motor Car Co., 24 East Concord street, Boston, Mass., are looking for the agency for some good medium priced car, preferably a two cycle one.

Dr. Hardin Reynolds and A. D. Reynolds, Jr., Bristol, Tenn., are erecting a two story 40x90 feet pressed brick building, the first floor of which will be use 1 40 a garage.

John O'Laughlin, Hays, Kan., has purchased a building site and will erect a garage thereon early next year. Mr. O'Laughlin has contracted for a number of Maxwell cars.

The Omaha Automobile Co. has decided to build a one story garage on Farnam street, between Nineteenth and Twentieth streets, adjacent to the company's present garage.

J. W. Hughes has purchased the Eureka Garage on Broadway, Seattle, Wash., the price paid being given as \$37,500. The location of the garage is on Seattle's automobile row.

The Studebaker Automobile Co., of Salt Lake City, Utah, are erecting a three story building at Second street South and Second street East, which will be finished in a short time.

H. O. Koller, Reading, Pa., will erect a three story brick and cement garage 29x230 feet, to cost \$18,000. It will be located on Fifth street, between Washington and Walnut streets.

The Midland Motor Car Co., of Moline, Ill., has established an agency in New York to be known as the Midland (N. Y.) Co., with premises at 1851 Broadway, in charge of J. M. Boyle.

The Escambia Motor Car Co., of Meridian, Miss., is building a new garage at the corner of Twenty-second avenue and Ninth street. The company handles the Oldsmobile and Interstate,

The Cloud Marts Co. have secured a lease on the store and basement at 1871 and 1873 Broadway, New York city, from the Welch Motor Car Co., of Pontiac, Mich. The store is to be used as an automobile sales com

as an automobile salesroom.

The Southern Motor Works, of Jackson, Tenn., have taken a twenty year lease on a property on Market street, and will at once commence the erection of a one story 100x114 feet garage, to cost about \$3,000.

F. S. Whitman and S. M. Storer, San Pedro, Cal., have taken a lease of the skating rink on Seventh street, which they will reconstruct as a garage. They have secured the agencies for the Chalmers-Detroit and Hudson cars.

The Albert Wegeman Garage at 106-108 Second street, Watertown, Wis., has been purchased by Edwin Bellman, of Milwaukee, and R. A. Fuller, of Green Bay, Wis. W. D. Francisco, of Fort Atkinson, Wis., has been appointed manager.

Jones' Garage at Mojave, Cal., was destroyed by fire on September 7, as was also one automobile in the place at the time. The loss is estimated at \$2,000. An adjoining garage was also set on fire and a six cylinder car in it was barely saved.

The Georgia Motor Car Co., agents for Stude-baker and E-M-F cars in Atlanta, Ga., of which George W. Hanson is general manager, have secured three additional stores adjacent to their former store, which will greatly increase their floor space.

The Peckham Motor Car Co., Dayton, Ohio, will move on October 1 into their new quarters at Second and Main streets, which are in the heart of the best residence district of the city. The company handles Peerless, Buick and Baker electric cars.

Agencies are being established in Wisconsin for the Fal car. by F. C. Van Sicklen, assistant sales manager for the Fal Motor Co., of Chicago. For the present, at least, the Milwaukee territory will be supplied by the Kopmeier Motor Car Co., 375 Summit avenue.

The Leigh Motor Co. has been organized in Leigh. Neb., by Gustav Hahn, H. P. Buhman and E.f. Wurdeman to take over the automobile business of S. B. Hosely. They will equip a modern garage and conduct a general garage business, handling the Maxwell and Studebaker lines.

The Elmore Motor Car Co. has been organized at New York city by George Post, who was formerly with Panhard-Levassor, and Peter Fogarty, one of the pioneer dealers in the city, who has recently been connected with George C. John. The new company will handle the Elmore in New York city and vicinity.

city and vicinity.

The Nebraska Buick Automobile Co. will erect a two story 75x135 feet building on Farnam street, Omaha, Neb., between Nineteenth and Twentieth streets. The building will comprise a salesroom 60x90 feet, and will probably be ready for occupancy before the end of the year. Lee Huff will manage the Omaha branch.

The Studebaker Co. of California has let the contract for a \$200,000 garage building, to be erected on Fremont street. San Francisco. The building will have ground dimensions of 275x87½ feet, and will run through to First street. The garage will be conducted as a regular public garage, and all makes of cars will be cared for.

The Mitchell agency in Milwaukee, Wis., conducted by the Browne-Friend Motor Car Co., and its successor, the G. W. Browne Motor Car Co., has been enlarged into a factory branch, and head-quarters have been established in a new building at 528-532 Broadway. The Browne Co. has taken on the Overland, and now carries the Marmon, Marion and Overland.

The stable of Kenny & Clark at the corner of Massachusetts avenue and Newburg street, Boston, Mass., is at present being transformed into a garage, and will be opened December 1 as the Charlesgate Garage. It is situated on the main artery of automobile travel from Cambridge to Boston. H. S. Merry, 121 Massachusetts avenue, will be manager of the garage.

An automobile building will be erected by Samuel Storrow, Pasadena, Cal., just south of the Hotel Green and west of the Santa Fé Railway station, at a cost of approximately \$25,000. The lower floor will be occupied by the Fair Oaks Garage, the Pasadena Taxicab Co. and the California Sightseeing Traffic Co. The second story will be leased for other purposes.

# New Incorporations.

The Wilmington Motor Car Co., Raleigh, N. C.—Capital stock, \$125,000. Incorporators, L. H. Simmons and A. L. Council.

M. S. Brigham Motor Car Co., Seattle, Wash.
—Capital stock, \$25,000. Incorporators, M. S.
Brigham and Caroline F. Brigham.

Royal Auto Co., Minneapolis, Minn.—Capital stock, \$50,000. Incorporators, I. A. Thorson, Lilian Thorson and E. G. Johnson.

Palace Automobile Co., Houston, Tex.—Capital stock, \$5,000. Incorporators, L. A. Pitts, R. P. Christian, J. F. Minton and others.

Excelsior Drug and Auto Co., St. Louis, Mo.— Capital stock, \$15,000. Incorporators, Gustav C. Menig, Anna Knipperberg and S. W. Jurgen.

The Auto and Aeronautic Supply Co., New York.— Capital stock, \$20,000. Incorporators, Percy A. Larter, Glen Ethridge and H. Chandler. Wordingham Auto Supply Co., Milwaukee, Wis.

-Capital stock, \$5,000. Incorporators, George D. Sheriffs, Wm. Wordingham and Thos. W. Sheriffs.

The Tate Gas Electric Motor Vehicle Co., Jersey City, N. J.—Capital stock \$100,000. Incorpo-

rators, John L. Tate, Chas. E. Tate and John L. Tate, Jr.

The New Albany Automobile and Carriage Co., New Albany, Ind.—Capital stock, \$5,000. Incorporators, L. C. Schwemberger, W. H. Thomas and Philip Scharf.

The Spring Tire Co., Los Angeles, Cal.—Capital stock, \$1,000,000. Incorporators, J. P. Magney, C. A. Bonnell, Edgar Sharp, J. N. O. Rech and Clem S. Glass.

United States Motor Truck Co., Cincinnati, O.—Capital stock, \$100,000. Incorporators, Harry L. Manss, Alfred Hill, H. B. Mackey, Jesse Lowman and Herman Erdman.

The Eastern Automobile Co., Bangor, Me-Capital stock, \$10,000. Incorporators, John H. Rice, Eben Leavitt, L. P. Swett, E. L. Miller, D. A. McLeod and J. F. Stevens.

California Electric Garage Co., Pasadena, Cal.— Capital stock, \$50,000. Incorporators, I. H. Stratton, A. W. Hookway, P. C. Dorland, C. H. Kay, R. C. Holbert and John Miliken.

The Bruce-Cubbins Auto Company, Memphis, Tenn.—Capital stock, \$10,00. Incorporators, N. S. Bruce, G. B. Malone, Jr.: M. M. McCallum, J. F. Cubbins & Kate F. Cubbins.

The Clark-Carter Automobile Co., Jackson, Mich.—Capital stock, \$100,000. Incorporators, H. E. Carter, F. C. Badgley, W. W. Clark, W. D. Thompson, L. H. Field, H. L. Hitch.ock, Geo. B. McQuellan, Claud McQuellan, Winthrop Withington, and Arthur Garland.

Ohio Electric Car Company, Toledo, Ohio.— Capital stock, \$75.000. Incorporators, Henry P. Dodge, Rathbun Fuller, Henry E. Marvin, James Brown Bell and Robert R. I.ee. To take over the business of the Ohio Electric Carriage Company, launched some time ago.

# Trade Personals.

Mr. Greenwood has bought out the interest of his partner in the Knapp-Greenwood Company, of Boston, Masa,

F. S. Jacobson has resigned from the Artizan Brass Company, Chicago, to accept a position on the Chicago American.

F. W. Lumsden, formerly local manager of the Ajax Tire Company in Seattle, Wash., has joined the Seattle branch of the Firestone Tire and Rubber Company.

H. S. Apperson, formerly sales manager of the Louisville branch of the Oldsmobile Company, has accepted a position as manager of the sales department of the Peerless and Knox agencies in Pittsburg.

A. F. Holden, who has been connected with the F. B. Stearns Company for six years, ever since he graduated from the Case School of Applied Science, has been appointed Western sales manager and will have charge of the territory between Salt Lake City and the Coast, Mexico and Canada.

F. H. Banbury, engineer of the Acheson-Oildag Company of Niagara Falls, N. Y., sailed for Europe on the steamer St. Louis on September 25. Mr. Banbury will look after the patent interests of the company in Europe. He will first go to Genoa, Italy, and later visit other countries to establish the Oildag process there.

# New Agencies.

Albany, N. Y.—R. M. Robinson, Reo. St. Louis, Mo.—J. M. Dunwoodie, Stearns. Marion, Ind.—Kent R. Wigger, Studebaker. Redlands, Cal.—Van Deventer Brothers, Ford. Los Angeles, Cal.—Frank C. Russell, Cadillac. St. Louis, Mo.—Oldsmobile Company, Oakland. Minneapolis, Minn.—A. G. Fitzgerald, Stearns. St. Paul, Minn.—A. E. Kelley, Stoddard-Dayton. Colusa, Cal.—Ruberts & Yerxa, Interstate Auto. Boston, Mass.—H. C. & C. D. Castle, Haynes. Portland, Ore.—Neate & McArthur, Locomobile. Grand Rapids, Mich.—Pantind & Bulkeley, Oakland.

Minneapolis, Minn.-Walter Rightmire, Stod-dard-Dayton.

Kansas City, Mo.—The Imperial Motor Co., Woods electric.

Kansas City, Mo.—The Long-Histed Motor Co., Overland, American Simplex.

**NUMBER 14** 

# Steering Wheel Switches a Convenience in Driving.

BY ALBERT L. CLOUGH.

A provision for controlling the ignition from the steering wheel adds materially to the comfort and safety of driving, and may be utilized to reduce wear and tear on certain parts of the car mechanism.

#### RIM SWITCH.

Steering wheel ignition switches may be obtained in various forms. A simple button, set into the wood rim of the wheel, may be had, the pressure of which acts to interrupt the circuit, if battery ignition is employed or to short circuit the armature, if a magneto is used, thus acting in both instances to stop the motor while the button is pushed. The button may be included in the common circuit of both batteries, if two sets are installed, and with most dual magneto systems it may be cut into both the magneto armature circuit and the battery circuit so as to be effective, whichever system the engine is running on.

Several car manufacturers are fitting these buttons to their wheel rims as a regular part of the equipment, and, when this is done, the wiring is brought up through the steering column and out to the rim in a manner which insures good insulation, and is not conspicuous. The button switch is intended primarily to effect sudden and temporary interruptions of ignition.

### LOCATION ON SPOKE.

Another form of switch, which is arranged to be clamped to a spoke of the wheel, is connected to the ignition system by means of conductors, carried in a length of flexible metallic tubing, which runs down the column from the wheel, through the floor or dash of the car.

This arrangement can be made to accomplish much more than the simple push button, as it is a regular switch and can be furnished with sufficient contact points to accomplish all that is required, without becoming at all bulky. The metallic tubing offers sufficient room for the necessary conductors. Such a switch is connected in parallel with the dashboard switching arrangements, and can be so arranged as to change from battery or magneto to "off" on a dual system, or from battery or magneto to "off" in case two entirely separate systems are used. It can even be so arranged that the two systems may be used simultaneously, although there is rarely anything to be gained by this practice.

#### BEST SWITCH LOCATION.

Considering the question of ignition switching, from the broad standpoint of convenience and car control, it is a grave question whether the steering wheel is not the logical place for the regular location of switching devices. It is easy to see why this function has hitherto been relegated to the dashboard. Switches naturally constitute a part of the coils which they control, and considerations of accessibility and cleanliness have rendered the dashboard location of coils preferable in many respects. Where the coils are located, there the switches which form a part of their containing boxes are naturally to be found.

Aside from the switching which is done preparatory to cranking the motor, all movements of switches are accomplished while the operator is in his seat. With the large steering wheels and heavily raked columns now in use, together with recessed dashes and the liberal leg room usually provided, reaching for dashboard switches becomes awkward and often entails a certain loss of steering control,

The control of spark position being always located on the wheel, it is not plain why the ignition switching should not also be placed there, thus centring all ignition control.

Before cranking his car the careful operator's first action is to make sure of the setting of the spark lever, and to see that the throttle is open the proper amount, and if the switching were regularly performed from the wheel the extra movement to the dashboard would be obviated. Accidents due to a too early setting of the spark would be less likely to occur, as the operator, in operating the switch upon the wheel, would be likely to note the position of the spark lever. In starting from the seat, after a short stop, during which the operator has not left the wheel, no movement from the comfortable driving position would be required. Of course the use of kick switches renders this possible also.

From the writer's standpoint it would not be strange if the wheel became the standard and not the exceptional location for the switch, and it is certain that in cars thus equipped at the factory the wiring could be well insulated and the switching arrangements rendered unobtrusive and not liable to interfere with other features of the control.

#### IMPROVED DRIVING CONTROL

With ignition control at the finger and, by the use of a steering wheel switch, it is possible to slow down for every bad crossing and pitch hole, by cutting off the ignition, and speed may also be slackened in this way when sharp corners are to be turned.

In the absence of such ignition control the clutch must be thrown out and the foot brake applied, in order to secure the required reduction in speed. The wear and tear of the clutch and brakes and the clutch and brake operating mechanisms thus occasioned amounts to considerable in the aggregate, and as the engine turns over at increased speed when the clutch is disengaged, it and its connected auxiliaries are subjected to some extra wear. There is also some additional expenditure of fuel thus occasioned. By cutting off the ignition the engine acts as a very satisfactory brake, and no extra wear is entailed. Either the simple push button or the complete steering wheel switch suffices for this purpose.

#### CHANGING FROM MAGNETO TO BATTERY.

Very few magnetos are so adjusted as to run their cars on the high gear at a sufficiently low speed to make driving safe in crowded traffic or over very rough level roads. The battery systems of such cars usually provide a very much lower minimum speed. In order to drive on the magneto under such conditions the clutch requires to be almost constantly slipped, and there is thus a good deal of unnecessary wear and tear thereon. An operator will often resort to clutch slipping, and even to a change to a lower gear, rather than reach down to the dash and change from magneto to the battery and coil system. With a steering wheel switch a mere movement of the finger suffices to change from one system to the

### DESCENDING GRADES,

In descending slight grades cutting off the ignition will usually keep speed within safe bounds without brake application, and slightly steeper ones require only a slight touch upon the foot brake as an addition to the braking effect of the motor. If a button or a switch is provided upon the wheel the chances are large that engine braking will be taken advantage of, but if no such device is in use it is more than likely that the freeing of the clutch and the application of the brake will prove a "path of less resistance" than stooping down and manipulating the dashboard switch.

It is a revelation to many who have not tried it to observe how nicely the speed of a car may be controlled in descending quite a steep hill by throwing into second speed and alternately cutting off and throwing on the ignition. Such a descent as this makes serious demands upon the brakes if the motor is not used as an additional resistance. Reaching for the dashboard switch while descending a rough, winding hill is by no means conducive to safety.

To those operators who think more of saving gasoline than sparing their brakes the ignition cut-out on the wheel also appeals. When a long hill is to be descended the clutch may be thrown out and the switch on the wheel thrown to the "off" position, the car being controlled during the descent by means of the brakes. At the completion of the descent the switch is thrown on and the clutch gently engaged on the high gear, thus starting the motor.

#### IN MEETING HORSES.

When a restive horse is met with or any other emergency occurs which requires the stopping of the metor, the steering wheel switch renders this instantly possible, without necessitating, upon the part of the operator, any change of position which may jeopardize the control of the car. As soon as starting of the engine is again required the switch on the wheel provides for "sparking it up" on the battery system, if a double system is in use.

Motorists who make a point of driving as quietly as possible will appreciate the ability to throw off ignition from the wheel. When making a stop the ignition circuit may first be interrupted and the hand throttle somewhat opened, and before the car ceases to move the clutch may be disengaged and the car be finally brought to rest by the brake. A stop can thus be made more quietly than with the traditional "steamer" and the cylinders still be left well charged for the next start.

### REAR SEAT EMERGENCY SWITCH.

In connection with the matter of ignition control there is one more suggestion which, though not entirely novel, may well be made here, namely, that every closed car, and perhaps every large touring car, should be equipped with an emergency switch capable, when operated, of infallibly cutting of ignition from the motor. This switch should be accessibly located within the body of a closed car, and, if used in connection with a touring car, should be within reach of the tonneau passengers. The passengers of a closed car are practically helpless in regard to stopping the vehicle unless such a device is provided, and the same thing is in a measure true of the rear seat passengers of an ordinary car. In case of disability upon the part of the driver, when no passenger is sitting beside him, a closed car would run wild until its engine stalled from the collision of the vehicle with some obstruction or from the nature of the road. A driver may faint or be intoxicated, or may be struck and rendered unconscious by a piece of timber projecting from the rear of another vehicle, or some other unexpected accident may happen. If an emergency cutoff switch were to be provided, to be used only under serious circumstances, it would afford the passengers in a closed car protection which they do not now enjoy.

# Trend of European Trade for 1910.

BY ROY LINDSAY.

During the past four seasons I have each season summarized for the readers of this journal the course of trade and possible prospects for the succeeding year, and reviewing my efforts in this direction I believe these forecasts have proved to be substantially correct. Twelve months ago I made it pretty clear that the trade in very large powered pleasure vehicles could not be expected to exceed 71/2 per cent. of the total turnover of all the European manufacturers, and actual sales for the 1909 season just closing fully bear out that contention. It is useless to attempt any sort of comparison between the demand as between the United States and Europe, because the former country is only commencing to approach the maximum demand for the high priced car, while Europe reached that position in the spring of 1908. To generalize is easy, but I will endeavor, by adducing concrete facts, to show why considerable caution ought to be exercised by American makers in attempting to place any considerable portion of their output east of the Atlantic.

I observe that a prominent American manufacturer has, after a tour of the European factories, expressed certain opinions concerning the likelihood of future automobile business between the two continents, but I must beg leave to differ absolutely from the conclusions he draws. The European automobile trade is a very difficult one to understand, and to realize all that is going on requires the closest attention, even by those, like myself, who in their journalistic capacity have access to information denied to the public or to fellow competitors in the trade.

The manufacturer referred to remarks upon the prevalence of taxicabs in Paris. London and other large centres on the Continent. His observations are correct only with respect to London, the large English towns and Paris. In France, outside the capital city, a taxicab would have to be searched for. In Berlin, owing to local conditions which cannot be discussed here in detail, these vehicles are a failure. The total in use in all other German towns does not exceed 100, and they are non-existent in any other European city. Warsaw (Russia) has just placed an order with an English firm for six, solely as an experiment, that is not likely to succeed owing to the roughly paved streets of that city. London has over 3,000 taxicabs, and these are being added to at the rate of fifty a week, one company alone owning 1,600.

### MOTOR BUSES.

In London 1,078 motor buses are in use at the moment of writing. There are very few in Paris, probably fifty all told, and these are being tested out by the company that holds a monopoly for bus traffic in that city under the supervision of the Paris Municipal Council, to decide the type that

shall be adopted when the concession is renewed in 1911. There are only six single decked motor buses in London, and no more will be built because the maximum of sixteen passengers they can carry does not pay running expenses at the prevailing low fares, which average one cent per mile. All other motor buses in London carry thirtysix passengers, and every order being placed for new vehicles stipulates for the same capacity. There are some 450 motor buses, all double-decked, running about in the provincial towns of England and Scotland, about seven in Berlin, and 150 would more than cover the number for the rest of the European continent, inclusive of four in Constantinople.

#### THE SMALL CAR.

Now let us consider the matter of the small car, which the above quoted manufacturer considers neglected in Europe. Because a very large number of limousine and landaulet bodied vehicles were observed on the Continent, it does not follow that these were built there. During the 1000 touring season many hundreds of British built cars belonging to British owners have been shipped to France, and seeing these on the roads in that country, and the places principally resorted to by tourists. would give a stranger the impression that such vehicles were in demand where seen, unless the country of origin was known. In proof of this fact it is sufficient to mention that the international triptyques issued by the three motoring organizations in England who look after these matters are practically double those of the same period in 1908, and I shall not be wide of the mark in giving the figures as exceeding 2,500. The reason why so few small cars can be observed on the European Continent is not because there exists a demand that cannot be supplied, but because the general population cannot afford to purchase them or go to the expense of running them even if they were given away free of charge. The class from which the American manufacturer of medium and small priced cars derives the majority of his customers-professional men, large shopkeepers, farmers and the like-does not exist in Europe. If the motor factories in France had to rely upon business from that country many of them would have to close down, for it must not be forgotten that there are very few large land owners, most all the country being parcelled out into minutely small divisions, owned by the peasantry who till them; hundreds of thousands do not exceed 2 acres in extent. Shopkeepers and professional men who have to earn their living out of the peasantry must conduct affairs on a correspondingly small scale, hence it comes about that a French country doctor or attorney must be content with an income below that earned by a skilled workman in

the United States. Germany possesses larger manufacturing resources, consequently is able to spend more money upon motor cars than its neighbor, but the proportion of large to small cars sold there certainly does not exceed the ratio of I to 99. Switzerland can be dismissed as a negligible quantity for a car maker because of the absurd restrictions imposed by the various cantonal authorities. (This statement seems hardly correct when regarded in the light of the latest French export statistics.-Ep.) Even supposing the country rich enough to purchase cars freely, which is not the case, Belgium cannot absorb a fraction of the cars produced in its few factories, England being the chief market for an output that, all told, does not reach 1,500 chasses per annum. The few orders that ever come out of Holland are fiercely competed for by its neighbors. The majority of the Italian population are very, very poor, cannot purchase sufficient cars to keep their own factories employed, and those persons who can afford the initial outlay are handicapped by a heavy duty on gasoline, which costs 56 cents per gallon. Russia, vast as it is, can only take high priced cars, and these are more than supplied to the big land owners and manufacturers by France. Spain has one factory producing the Hispano-Suiza car, but so small is the demand, because of the notoriously bad roads, that attempts are being made, without success, to sell the machines in England. Portugal, Tnrkey, Norway, Sweden and the principalities in southeastern Europe must always remain, for geographical considerations, outside the car maker's programme.

#### THE ENGLISH MARKET.

England, with which can be included Wales, Scotland and Ireland, is a market that appeals very temptingly to American manufacturers, but I want to impress upon the American sales managers the serious difficulties encountered in attempting to find business in England. Eight years ago, before more than a handful of English factories existed, the Locomobile steamer and the Oldsmobile gasoline runabout sold in quantities, until purchasers discovered their faults, and thenceforward would have nothing to do with American cars in any shape or form. One car built in a Western State was handled here for eighteen months from a depot in the best district of London, was well advertised and pushed among the agents, yet only a few were sold. The most recent introduction favorably impressed me by its low prices and seemingly good features that would take the fancy of the British public, but when I went into details it was to discover with astonishment that, although there is a four cylinder engine and a selective type of sliding change gear, this last possesses only two forward speeds. And people here have been agitating for four forward speeds even on cars as small as 12 horse power. This same vehicle has so called "stream line" front mudguards, very small steps, and not a vestige of running board or accommodation for luggage for a tour, generator for acetylene lamps, or any place to carry a spare wheel. I could point out a dozen other things on this same vehicle that spoil it for the English market. I do not doubt for a moment that this car is soundly constructed, and more than worth the remarkably low price at which it is offered here.

NUMEROUS ENGLISH MAKES OF SMALL CARS.

A few months ago an illustrated article by the present writer appeared in these. pages, describing a few of the more prominent small cars sold in England. It is possible today to purchase four cylinder, 15 horse power cars from English factories. Many of these firms also build large cars, and while some few, such as the Daimler and Napier, have only recently fallen into line with the rest, there are plenty who achieved their first reputation with the small single cylinder or two cylinder machine, and have consistently devoted most attention to the development of this class. Rover, Swift, Riley, Star, Phoenix-a haphazard selection-are probably unknown names in America, but in England and the British colonies they sell in largely increasing numbers. These and many others were in use long before most existing American factories had been erected. They have been evolved by the genius of British designers, and for consistent reliability will stand the closest comparison with anything produced elsewhere.

## ECONOMICAL OPERATION REQUIRED.

To attempt to give a list of the French and German firms turning out perfectly designed and beautifully finished small cars not exceeding 15 horse power would mean a complete directory of the automobile trade in those two countries. Perhaps it may be news to American readers that the world famous German Daimler Company has built cars of that small power, and several are actually sold and being used by purchasers. The same thing is true in respect to every factory, and a man with \$1,250 to spend is not limited in his choice; on the points of speed, hill climbing, engine flexibility, comfort of passengers and reliability, it is really astonishing to count the number of good makes that are purchasable at the price just mentioned. Nor have the makers on this side fallen into the mistake that their American competitors have committed, by offering comparatively large horse power for little money. I do not know how the purchaser of this class of machine looks at things in America, but what is within my knowledge is the fact that east of the Atlantic the annual running expenses and upkeep must be reasonable. There is small consolation for a man who can climb a hill 5 miles per hour faster than his neighbor, who owns a machine of three-quarters the horse power that costs the same money, to find that the latter costs \$250 a year less for gasoline. Fuel consump-

tion contests have been an important portion of the programme of English automobile clubs for many years. I am not referring to the Royal A. C., but rather to the dozens of local organizations in every part of the kingdom that run off at least two, sometimes more, such contests each year. The trade have nothing to do with them, competitors using their own machines, which they take great pride in tuning up so as to obtain the last fraction of power out of every drop of fuel. The results of these competitions secure wide publicity, and thus it comes about that certain machines become branded with unenviable reputation as fuel wasters, irrespective of the sort of carburetor fitted.

FACTORY EQUIPMENT.

It has been alleged that British makers suffer for lack of modern machinery. I have been privileged to wander at will through every British automobile factory worthy of the name, and cannot recall a single place where machine tools of native origin do not largely predominate. American tools are found in every factory, but so also are German, and, to a very small extent, French tools, these last confined to small repetition work in brass. Not having to pay heavy import duties on raw material or manufactured goods, British makers are able to pick and choose their machine tools from every country; results, plus absence of repairs, are the factors which decide where orders for tools shall be placed. France is in a somewhat different position because most of the big factories were started on a very small scale nearly two decades ago and have grown gradually with the demand, consequently the tools employed seem, to a cursory onlooker, somewhat antiquated. But they are not so in reality, and the exquisitely finished chasses that come out of the good French factories constitute a sufficient answer to the supposed want of enterprise. Germany has little or no need to look outside its own borders for tools when one remembers that in one branch, viz., the generation of true epicycloidal teeth on bevel wheels, we Britishers unreservedly admit the German tool makers to be the leaders.

#### TREND OF TRADE.

The trend of trade in England during 1010 can be fairly summarized in a few sentences, because most of the important points have been brought out in the preceding paragraphs. Single cylinder machines of 8 horse power, selling for \$650, suitable for doctors' use, are not likely to continue their present popularity when plenty of two cylinder, to horse power cars can be had for another \$150. The four cylinder type, ranging from 12 horse power up to 16 horse power, will be the leading line with every maker. The two seated racing style of body, set right back above the rear axle, and an exaggerated rake for the steering column, for which there has been a craze this last year, is disap-

pearing, want of comfort and entire absence of luggage accommodation being the reasons for people asking to be supplied with something on more rational lines. Where only two seats are fitted, these will be situated nearly midway between the front and rear axles and the steering column brought up proportionately to a smaller angle with the floor boards. The five seated side entrance body is still the most popular

and is not likely to be altered, but an addition will be made in the form of doors to the front seats, as high as the dashboard. On mechanical details it is impossible to give the slightest forecast at the time of writing, for the good and sufficient reason that the doors of every factory are jealously guarded against the intrusion of strangers while the new models for the Olympia Show in November are being pushed ahead.

# Shock Absorbers.

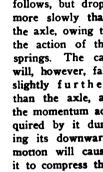

By FREDERIC STRICKLAND.

The action of the so called shock absorbers is not well understood by many motorists. In practice their principal object is not to absorb shocks, but to prevent the recoil from the springs. The object of the springs which carry a car is to prevent the body of the car from following the inequalities of the road. Without springs the car would naturally almost exactly follow the contour of the road, and as the road surface is far from smooth the result would be great discomfort to the passengers. If we could

length as carriage springs. There is a limit, however, to the length of springs practicable in a car, as if they are too easy the car sways unpleasantly, and it is quite possible for this motion to be so bad as to make the passengers seasick. In practice one of the great difficulties

of comfortable springing is to avoid an unpleasant recoil from the springs when the latter are compressed by a bump in the road. This action will be seen from Fig. 1. As the car comes to a hollow in the road the axle drops into it. The car

> follows, but drops more slowly than the axle, owing to the action of the springs. The car will, however, fall slightly further than the axle, as the momentum acquired by it during its downward motion will cause it to compress the spring beyond its

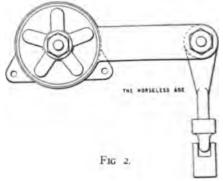

If at this moment the road normal. resumes its normal level the spring will be still more compressed, and on the axle getting to the normal level a great part of the power spent in compressing the spring will be given out again, and the car will be lifted a good way above its normal level. The action will be somewhat as shown in the figure. No spring gives out the whole of the power put into it, owing to the internal friction of the spring itself, but most springs give back so much that a very unpleasant motion is caused to the car. This is most unpleasant when it happens to the back wheels, especially if the front wheels happen to pitch into a hole at the same time that the back of the car goes up. The result then is that the back of the seat hits one in the back. The shorter the wheel base the worse this action is.

A shock absorber consists of a device for increasing the friction of the spring, so as the prevent its lifting the car to the extent it otherwise would do. The majority of designs consist of some sort of friction brake attached to the axle by a lever, a simple form being shown in Fig. 2. It is obvious that such a device can be made to entirely prevent the recoil of the spring

if the friction in it is great enough, but that any action it has in this way also has the effect of reducing the motion of the spring all round. Thus if the friction was made great enough the effect would be to prevent any motion of the springs whatever, and the result would be the same as if there were no springs. The adjustments of such devices must, therefore, be a matter of trial and error, in order to get the best result. If the friction is too great there will be not enough give in the springs, while if it is too little there will be too much recoil. In order to get over this difficulty, some shock absorbers have been made with a ratchet arrangement so that they do not interfere with the car moving toward the axle, but introduce a good deal of friction when it moves away from it. This is probably an improvement. In some cases the device is so arranged that there is no friction at mid-position, and for a little way on each side, but it increases rapidly as the body departs from this.

It may be observed that the whole question of shock absorbers is dependent on the amount of internal friction of the springs themselves. It is obvious from what has been said that the effect of the shock absorber is principally to increase the internal friction, and that if springs could be made with enough internal friction, no shock absorbers would be required. The internal friction of springs varies enormously according to their design and material. Spiral springs, for instance, have very little, and hence are seldom employed alone for vehicles of any kind, as they have a great tendency to oscillate. The friction of plate springs depends on the number of leaves and their material. As the spring gives, the leaves have to slide over each other and thus develop friction. Springs of equal strength may be made with a few thick leaves or many thin ones, but the latter will have much more friction than the former. Springs of equal width and thick-

ness of leaves may also be made either of steel tempered as hard as it can be made without breaking, or they may be as soft as possible without permanently deflecting. In the latter case about twice as many leaves will be required as in the former. other things being equal. The friction between the leaves will therefore be much greater. In addition to this, the soft leaves have a great deal more friction in the steel

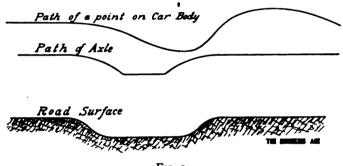

Fig. 1.

have a car perfectly sprung, however, the car itself would travel in a level line while the axle would follow the inequalities of the road, being kept in contact with it by the springs. Such a result is, of course, quite impossible, because it would require springs of infinite length. In practice the springs must have considerable stiffness in order to give the car sufficient stability, and all one can do is to so arrange them that the movement of the springs due to the inequalities of the road are converted into long, easy motions, which do not cause any discomfort to the passengers. The length and stiffness of the springs necessary for any particular purpose can only be settled by experiment and are different for different types of road, different bodies, etc.

Carriage builders found out many years ago that for comfort springs of good length were necessary; but the early European motor cars were entirely governed by racing, in which the whole object is to cut down weight at the expense of comfort, and therefore the shortest springs are used which will avoid breakage of the machinery. Since racing ceased to have so much influence on car design springs have been greatly lengthened. till they now are about the same

# THE HORSELESS AGE

9-15 Murray St., New York. Every Wednesday.

Publishers:

Fred J. Wagner, Charles B. Ames.

EDITORIAL STAFF.

P. M. Heldt,

Albert L. Clough, F. E. Watts.

ADVERTISING STAFF. R. S. Richardson,

E. L. Waldteufel, J. T. Coventry. Gus H. Johnson, G. R. Purvis.

SUBSCRIPTIONS (payable in advance), DOMESTIC, \$2.00 a year; CANADA, \$3.00. All other foreign countries included in the Postal Union, \$4.00. Single copies, 10 cents.

BRENTANO'S, 37 Avenue de l'Opéra, Paris.

COMMUNICATIONS.—The Editor will be pleased to receive communications on trade topics from any authentic source. The correspondent's name should in all cases be given as an evidence of good faith, but will not be published if specially requested.

Address all communications and make all checks, drafts and money orders payable to THE HORSE-LESS AGE, 9-15 Murray street, New York.

Entered at the New York post office as secondclass matter.

One week's notice is required for change of advertisements.

Telephone: 7195 Barclay,
Cable: "Horseless." New York and London.
Western Union Code.

THE HORSELESS AGE has been purchased from E. P. Ingersoll, the founder and owner of the paper, by the undersigned, who will conduct it in the future.

FRED J. WAGNER, CHARLES B. AMES.

# The Commercial Aspect of Road Races.

It is perhaps only natural that with the multiplication of road races this year there should come complaints about poor financial returns. Our readers will remember the reports of a deficit of about \$30,000 in connection with the Crown Point-Lowell race. The Long Island Motor Derby, held in the vicinity of New York during Hudson-Fulton week, which was evidently organized in the hope of attracting some of the hundreds of thousands of country visitors then in the city, is said to have proven an unremunerative enterprise from the standpoint of the promoter, who is quoted to the effect that he is through with the organization of road races. Even the Lowell, Mass., carnival, which was heralded as a great success in every other respect, appears from an interview published in a Lowell paper to have resulted in a financial loss.

The reports of the tremendous attendance at the last several Vanderbilt Cup races, no doubt, gave the incentive to the organization of road races that are being held all over the country. The word has been passed that the general public is becoming interested, and that much greater crowds can be reckoned upon than in former years. But with the increase in numbers has come a decline in quality, and the amount of money spent per capita is much less than it was in former years, when only "automobile enthusiasts" attended races. At the same time the expenses of organization have increased, owing to the precautions for the safety of the public and the drivers insisted upon by the A. A. A. and the manufacturers. The expense of organization, including the necessary outlays for procuring permits and securing entries, together with the sanction fee, the cost of oiling and guarding the roads and that of erecting the grand stand, make a properly organized road race quite an expensive affair. A study of the above items of expense may also shed some light on the reasons which led the Cups Holding Association to shorten the Vanderbilt Cup course this year from 20 to 12 miles, in round figures.

On the other hand, nobody can be compelled to pay for the privilege of seeing a race held on public roads. The returns from such a race are limited to the entry fees, the proceeds from the sales of grand stand seats and the amounts obtained from the sale of programs, from program advertisements and from various small concessions. In France, where suitable courses are found in abundance, the race promoters exact very large bonuses from the localities in which the races are held, but in this country, where closed circuits of improved roads near large cities are relatively few in number, there is no such keen rivalry between different sections as to prompt them to offer large bonuses to the race promoters.

Whether or not a race proves profitable depends primarily on two things, viz., the amount of advertising it receives in the press and the judgment of the men in charge. If a race is widely heralded in the press it is sure to be largely attended, but a large attendance is alone no guarantee of financial success. If the promoters demand extortionate prices for seats, or are too optimistic in making estimates of the grand stand accommodations required, the venture is likely to prove a failure.

# Automobiles and the Hudson-Fulton Celebration.

It must have occurred to many of those connected with the automobile industry and trade who witnessed the Hudson-Fulton celebration in New York last week that the automobile played a rather inconspicuous part in this celebration. The events of the week were naturally largely of a marine character, as befitted a commemorative event in honor of an explorer's voyage and of the invention of steam navigation. But in addition to the naval parades, motor boat races, regattas, etc., there were a considerable number of festivities on shore, and had the event occurred ten years earlier there is very little doubt that an automobile parade would have been included in the program. However, the time when the automobile was an object of public curiosity has passed, and there is no reason why it should be regretted. The motor vehicle is no longer in its infancy, but has assumed its proper place in our everyday life. Indirectly the automobile had a great deal to do with the celebration, and the officials and employees of our taxicab companies especially will probably long remember the demands made upon their services during the event. Many of the visitors to the metropolis during the past week will carry home with them impressions of the convenience and comfort of the motor cab, and few will return home without having been impressed with the large part the automobile now plays in the traffic of our big cities, and with the importance of the automobile trade, which occupies block after block of New York's main commercial avenue.

#### Cold Weather Warning.

In a few weeks sharp night frosts may be expected in the northern section of the United States, and those who drive or care for water cooled cars are herewith warned to take the proper precautions to prevent injury to their cars from freezing of the cooling water. Most cars will be kept in use for at least two months longer before they are definitely stored away for the winter, and it is during the months of October and November that most freezing accidents happen, chiefly because cold snaps then often come unexpectedly. During this period each year many cylinders are cracked, owing to the carelessness of those whose duty it is to look after the cars. This always involves an expensive repair or replacement, and the replacements are the more onerous now that twin cylinder and quadruple cylinder castings have largely replaced single cylinder castings.

As early in the season as there is any likelihood of sharp night frosts in the particular locality, either the regular cooling medium should be replaced by some fluid with a low freezing point, or else, if it is intended to use the car only a few times before putting it away for the winter, the cooling system should be thoroughly drained before turning the car in when returning from a trip. The most commonly used non-freezing cooling fluid is probably a solution of wood alcohol. A solution made up of one part of wood alcohol to two of water freezes at about minus 12 degrees Fahrenheit. Some use a solution comprising one part of wood alcohol, one part of glycerine and four parts of water, which freezes at about minus 15 degrees Fahrenheit. Calcium chloride solution is also used. Three and one-half pounds of the hydrated chloride to one gallon of water gives a solution which freezes at minus 8 degrees Fahrenheit. When the latter solution is used care must be taken to remove any acidity present by adding lime until the solution turns red litmus paper blue, otherwise it will attack the metals of which the parts of the cooling system are composed. Later on, if the temperature happens to be much below the freezing point, it is a good practice when leaving a car at the curb for a considerable length of time to throw a robe over the radiator so as to keep the heat in. On cars with a very energetic cooling system it is often advantageous to remove the fan drive during the winter, which will cause the motor to operate at a high cylinder wall temperature, and thus more efficiently.

### Soft Edged Seat Cushions.

Increasing the wheel base, improvements in springs and the adoption of larger wheels and tires have rendered the modern automobile conveyance of the utmost luxury. Attention has also been paid to the upholstery and very thick spring cushions have taken the place of the thinner hair filled cushions, with very few or no springs, which characterized the earlier motor cars. It is now so common for automobiles to be used for continuous all day drives, covering hundreds of miles, that the most extreme care must be taken to secure comfortable seats, in order that the fatigue and stiffness which are likely to arise from the protracted continuance of a nearly fixed position may be reduced as much as possible.

This consideration has led to the bringing out of the soft edged cushion which characterizes many of the 1910 models of high grade cars, and bids fair to come into general use. With the ordinary type of spring cushion, while the weight of the body as a whole is comfortably supported, there is a certain tendency toward fatigue and chafing at the points where the limbs rest upon the front edge, which is of an unyielding nature, as the frame of the cushion is a continuous edging of wood bent or sawed to conform to the required outline.

In the soft edge cushion the wooden frame is omitted along the front edge, the flexible leather covering only being used there, and the springs being held in place by sheet steel pieces running from side to side of the wooden frame. The edge thus conforms perfectly to the contour of the part of the body which rests upon it and a much easier seat is thus obtained, the front leather and the springs back of it giving in the required degree.

Details such as these, though minute in a way, are of immense importance in helping to make the motor car what it should be—the most comfortable highway conveyance.

#### The Demand for Machine Tools.

Probably the need for additional machine tools has never been more acute in the automobile business than it is at the present time. With a large number of new companies entering the field, and most of the established companies building additions, tools of all kinds are needed to turn out the required number of parts.

The trend of manufacture is indicated by the increasing orders for automatic machinery and the frequent newspaper ads for competent screw machine men. A considerable number of special machines are being brought out. Most of these are designed to reduce the amount of handling necessary to finish a piece. Every effort is made to bring as many tools as possible to work upon the piece at a single setting. This accomplishes two objects: It reduces the time of handling and the liability to mistakes.

As a result of this increased demand, which is especially great along certain lines, the time required for the delivery of machine tools is increasing. As is usual in such cases, a few wideawake manufacturers of machinery are getting a large share of the business, but the present demand is large enough to enable many more to profit by it. Those makers of machines who have not already studied the requirements of atuomobile manufacturers would be well

advised if they were to investigate the situation.

#### French Auto Taxation.

The automobile tax laws passed by some of our State legislatures last winter stirred up considerable opposition, it being claimed that the imposition of a special tax on automobiles, in addition to the personal property tax collected on them in many localities, constitutes double taxation. However, when the amounts involved are considered and compared with what auto owners in some foreign countries are compelled to pay American motorists may consider themselves fortunate. Double taxation may be unconstitutional in this country, but in France the National Government levies a tax against the motorist first on the number of seats on his car and then on the number of horse power developed by its motor, and when the National Government gets through with the motorist taxpayer the municipal authorities take him in hand and tax him according to the same schedule.

Not satisfied with taxing the car, the French Government also collects a heavy duty (7.5 cents per gallon) on gasoline, and the municipal authorities of Paris collect an octroi duty on gasoline entering the city amounting to twice the Government tax. The sums which thus flow into the national and municipal treasuries out of the pockets of motorists in the course of a year are almost staggering. The whole subject is receiving a thorough airing at the present time, owing to the attempt of the French Minister of Finance to still further increase the schedule of taxation. One of our French contemporaries publishes a table of the direct and indirect taxes borne by the owner of a 30 horse power car in Paris, on the assumption that he burns about 1,000 gallons of gasoline a year. In that case the state and municipal taxes on the car and the taxes on the fuel amount together to \$325. It is quite conceivable that many people in that city are deterred from purchasing automobiles by these high taxes. More than half of the amount consists of the indirect taxes on the fuel, and motorists in this country may consider themselves fortunate that very extensive sources of gasoline are found within the country, and that they have tax free fuel

The A. C. of Switzerland, which has its headquarters in Geneva, will hold an automobile show in May, 1910, combined with a show of aeronautic apparatus.

## The Taxicab Business in Paris.

By P. MAISONNEUVE.

In Paris there are at present 3,312 motor cabs in public service, of which 282 are the property of their drivers, while the rest belong to operating companies, the principal ones among which are the following:

Compagnie Camille.

Compagnie des Auto-Fiacres.

Compagnie des Automobiles Météor.

Compagnie Génèrale des Fiacres à

Compagnie Parisienne des Voitures de Place Automobiles Francia.

L'Urbaine.

Bondis & Cie.

Compagnie des Auto-Taxis De Dion-Bouton.

Compagnie des Automobiles Ours.

The Ours taxicabs are operated by the manufacturing company of that name, and the De Dion-Bouton cabs are operated by a subsidiary company of the large De Dion manufacturing firm. The other companies are entirely independent, and certain among them, such as the Compagnie Camille, the Compagnie Générale des Voitures à Paris and L'Urbaine are horse cab operating companies, which in recent years have supplanted some of their horse equipment with motor propelled cabs and are now operating both horse and motor cabs.

The principal makes of chassis represented by the 3,312 taxicabs in actual operation are the following:

Renault two cylinder, 7-10 horse power.

Unic (Georges Richard) two cylinder, 8-10 horse power, and four cylinder monobloc, 10-12 horse power, with two bearing crank shafts.

Bayard-Clement four cylinder, 12-16 horse power, and (recently) single cylinder, 8-10 horse power, which are very short and have the control at the left.

Delahaye two cylinder, 10-12 horse power, and four cylinder, 10-14 horse power. De Dion-Bouton single cylinder, 8-10

horse power.

Ours, three cylinder vertical, 14-16 horse

Krieger-Brasier, four cylinder, 15 horse power, with electric transmission to the front wheels.

Charron, two cylinder, 8-10 horse power.

In addition to the above, a few cabs of many different makes are met with on the streets of Paris, but the majority of them belong to the drivers themselves.

In accordance with the regulations to which all other motor vehicles are subjected, taxicabs must be capable of turning in a circle of 7 metres (20 feet) radius. The drivers are submitted to a special examination, known as the "coachman's examination," which bears mainly on the geography of Paris. They, of course, must have the regular driver's permit required of every automobile driver.

The bodies employed are all of the so called landaulet type, that is to say, with a folding rear portion, giving at will an open or closed vehicle. The driver is protected by a small hood which can be extended when it rains. Those cabs which have the control members at the left have a place at the side of the driver where trunks or other baggage may be carried, for which an extra charge is made, The rates of fare are not uniform. They always comprise an initial charge of 0.75 franc (15 cents), and this entitles the patron to a ride of 1,200, 900 or 600 metres (three-quarters, nine-sixteenths or three-eighths of a mile), according to the type of vehicle and the number of passengers carried. The tariff No. 2 is applied when more than two passengers are carried. The next charge to be registered by the instrument is 10 centimes (2 cents), and entitles the patron to a ride of 400 metres, 300 metres or 200 metres (one-quarter, three-sixteenths or one-eighth of a mile), or fraction thereof, according to the tariff of the vehicle. The charge for waiting four and onehalf minutes is the same as that for driving I kilometre (five-eighths of a mile). If the fare wants to go outside the fortifications of Paris he is obliged to pay 50 centimes (10 cents) extra, and if he discharges the cab outside of Paris he is obliged to pay an extra charge for the return trip, which is calculated by the aid of a map issued by the police department of Paris.

After having thus outlined the general conditions of operation, let us look a little closer into the question of the receipts necessary in order to make the services pay. The operating costs are made up of the following items:

1. General expenses, including rent of offices and garage, salary of officials, etc.

2. Amortization of the rolling stock.

3. Repair of rolling stock.

4. Wages of drivers, cost of fuel and oil. This latter item is proportional to the receipts.

The receipts consist solely of the payments for trips made by customers of the company, and this varies between 30 and 60 centimes per kilometre. The outlay for fuel and oil is proportional to the daily mileage, and amounts to 8 to 10 centimes per kilometre covered. The driver who is made this allowance is thus free to use either gasoline or any other fuel he may desire. As gasoline sells in Paris at present at 57 centimes per litre (42 cents per gallon) the majority of the taxicab drivers use a fuel with a benzol base, that is to say, hydrocarbons derived from coal tar, the price of which in Paris ranges between 35 and 40 centimes per litre (about 30 cents per gallon). This fuel, which is also used for the motor buses operated in Paris, does not give very good results on vehicles which are not specially adapted for it. The majority of the

Parisian taxicabs give off a disagreeable odor and smoke, notwithstanding the fact that this is forbidden and punished by fines in Paris.

The tips paid to the drivers are theirs, in addition to the commission paid them, which varies between 15 per cent. and 35 per cent. of the total receipts, according to the amount of the latter. Notwithstanding the large number of motor cabs in service at present, the drivers earn an average of from 10 to 15 francs (\$2 to \$3) per day.

It is to the advantage of the drivers to see that their vehicles are not out of commission, for each day the car spends in the repair shop is a period of idleness for the driver, except under specially favorable conditions, when there is a "free" car at the garage, or one of the drivers is absent, due to sickness or some other cause. The cars leave the garage in accordance with the public demand for transportation facilities, at three periods of the day, as follows: In the morning from 9 to 10 o'clock; in the evening at 6 o'clock, and (a few vehicles) at 9 o'clock. The first vehicles return to the garage between 7 and 9 o'clock in the evening, and the others between midnight and 2 o'clock in the morning. The latter are used for the night service.

The cab stands do not belong to private companies, but to the Paris city administration. There are 301 such stands in the city, which are under the direct control of the chief of police. At each of these stands there is a "complaint book," in which patrons may jot down any complaints they have to make. If any of these complaints are found to be justified the drivers concerned are punished by periods of suspension or by fines.

Vehicles which are not fitted with taximeters are rented by the day, the week or the month, but the rent for a 14 to 20 horse power landaulet is 1,000 to 1,500 francs per month. These vehicles carry no other visible inscription than a red stamp of the police department on the number plates. The taxicabs, on the other hand, must carry numbers on their lamps and have colored glasses, each of the different stations having a special color.

A number of the operating companies which are affiliated with manufacturing companies do their own repair work. The majority of these conduct a repair shop in which to make their minor repairs and have a contract with the manufacturer for furnishing renewal parts. Some of the companies figure on a three year amortization, and others on a five year amortization, but the vehicle bodies need renewal long before that time. From an inquiry made by the writer it results that the relative frequency of mechanical troubles with the different parts is as shown by the following table.

No mention is made in the table of the motor, which rarely gives trouble. It occasionally happens that

balls in the crank shaft bearings break. With built up crank shafts the parts will sometimes come loose. This trouble is peculiar to one make of cab.

	r Cent
Change gear	40
Differential gear and propeller shaft	20
Ignition	10
Axles, spindles and wheels	20
Steering gear	5
Clutches, etc	

The cost of pneumatic tires, whether they are furnished by the manufacturers under contract or whether they are purchased by the operating companies under a special agreement, is about 10 centimes per vehicle kilometre (3.2 cents per vehicle mile), based on the total running distance and not on the paid mileage.

A somewhat similar service to the taxicab service is conducted in connection with some of the railway depots in Paris, either by the railroad companies themselves or by companies having a concession from these companies. Two of the companies having depots in Paris. viz., the Paris - Lyon - Mediterranée Railroad Company and the Orleans Railroad Company, operate these services themselves. They employ LaBuire chassis, the same make which is employed in the postal service. These vehicles serve for carrying travelers from their homes to the railroad station, and vice versa.

The fare varies according to the number of seats of the vehicles, but is not less than 5 francs (\$1).

Much more important than improvement in the mechanism of the motor cabs is a better training of the drivers. The majority of the drivers drive much too fast and recklessly, at the risk of damaging their machines by abrupt braking and sudden gear changing, and causing frequent accidents.

#### Another Rise in Tire Prices.

The unprecedented rise in the market price of crude rubber has forced a second general increase in automobile tire prices within eighty days and calls attention to the increased demand for rubber gum which has followed the expansion of the automobile industry.

"The tire output of this year will total nearly \$30.000,000," states H. S. Firestone, "and next year's production is expected to run between \$45,000,000 and \$50,000,000."

"The rubber harvest has shown an average annual increase of only about 11 per cent. for several years, which is barely enough under normal conditions to keep pace with general business requirements. It is owing principally to the recent large demand and to local conditions in the rubber districts that fine Para rubber has steadily risen from 67 cents a pound in February, 1008, to the record price of \$2.15 which now prevails for immediate delivery. There is very little to be had even at that price."

# Automobiles and Sanitation.

By Albert L. Clough.

Public opinion and sanitary authorities are now fully awakened upon the subject of the part played by the common house fly in disseminating disease, and it is interesting to note that there is an important connection between this subject and the automobile.

The house fly deposits its eggs in decaying refuse of various kinds, but the natural place of deposition is in the dung of animals. Horse manure is the usual medium chosen. The fly larvæ, emerging from the eggs, feed upon this decaying matter, and finally emerge as fully formed flies. Unless horse manure or some equivalent form of offal is present in a certain locality no flies can be bred there, as no food for the fly larvæ is at hand.

In cities and towns, in recent years, garbage and animal wastes have generally been carefully disposed of, with the exception of the collections of manure in stables. Swill is promptly collected, the keeping of swine, hens and cows has been largely abolished; but the public and private horse stable has been and is still allowed in most urban districts, as being a necessity.

Under these conditions the stable has furnished the main breeding place for house flies, and a very prolific one, notwithstanding municipal regulations enforcing the frequent cleaning out of barn cellars and the like.

Within the last few years, however, a decided change has been wrought by the introduction of the automobile in certain parts of most cities and towns. A good many public stables have been converted into public garages or discontinued altogether, and a very large number of private horse stables are now used to house motor cars instead of horses, or contain fewer horses. In instances where both horses and cars are kept in the same building greater cleanliness is generally observed in consideration for the finish of the cars there stored. In many towns and small cities where the automobile has made extensive progress a great many private stables have been built over into small tenements for renting purposes.

Another cause which has tended to the diminution of the number of stables has been the disinclination upon the part of timid people to drive horses in good automobile districts. Innumerable driving horses have been given up on this account by ladies. Furthermore, trolley lines are continually being extended, and a large class who formerly used horses now use the electrics.

Upon a number of occasions within the last year or two the writer has heard comment made upon the relative scarcity of flies in certain residence districts, and in each instance it has been found, upon investigation, that many of the stables

in the near vicinity had recently been transformed into private garages or given up.

Fearing to conclude too hastily that there was any connection between this fact and the observed scarcity of flies, an expert entomologist was consulted, who gave the opinion that the causal connection was a valid one. It appears that house flies do not, as a rule, move very far, in their short lives, from their breeding places, unless under the action of winds, and thus it is possible to study separately a particular district.

Apart from the matter of stables is that of street dirt as affected by the automobile. Unpaved streets are seldom swept and the horse droppings thereon are breeding places for flies. When the automobile traffic over such a street has displaced, in a large degree, the horse drawn traffic, the condition of the street as a "fly nursery" becomes much less favorable.

It may now be taken as a fact that the introduction of the automobile has progressed far enough to make a sensible difference in the number of these disease bearing and annoying insects which are bred in certain residence localities of our cities and towns. An entomological friend says that if the good work continues and eventuates we shall have no flies, and he is even inclined to extend the decimation to the English sparrow.

The automobile is blamed for all kinds of evil. When a good word can be said of it, let it be shouted from the house-tops!

# Studebaker Branch Managers' Convention.

Twenty-four branch managers of the Studebaker Automobile Company attended the annual convention at South Bend, Ind., last week. Among the incidents of the week was a tour of inspection in electric cars through the large carriage and wagon factory of the company in South Bend. From South Bend the party of branch managers, accompanied by officials of the company, made a trip to Detroit in a special car, and from there they went on to Elyria, Ohio, at which latter two places they inspected the different factories in which the various Studebaker gasoline cars are manufactured.

# Sibley Motor Car Company Organized in Detroit.

The Sibley Motor Car Company has been organized and incorporated under Michigan laws to manufacture a popular priced touring car and roadster. Plans are being developed for a quantity production next year. The incorporators are Frederick M. Sibley, Henry Wineman, Jr., John G. Utz and John B. Phillipps. Mr. Utz and Mr. Phillipps were formerly associated with the Chalmers-Detroit Motor Company as chief engineer and superintendent, respectively.

# **NEW VEHICLES AND PARTS**

### Rambler 1910 Models.

The Rambler line for 1910 will comprise five models built on three different chassis. All are four cylinder machines equipped with magnetos and 36 inch wheels. The new models and the prices are as follows:

Model 53, five passenger touring car, \$1,800.

Model 54, five passenger touring car, \$2,250.

Model 54, four passenger close coupled car, \$2,250.

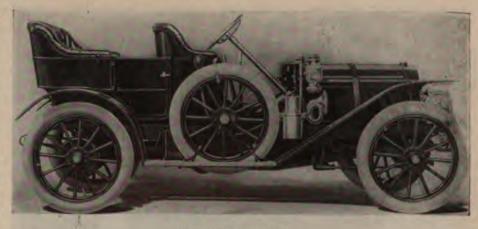

\$2,250.

Model 55, seven passenger touring car, \$2,500.

Model 55, seven passenger limousine, \$3,750.

The design and material of the engine, transmission, drive shaft, axles, frame and wheels are the same for all three chassis, and the differences relate to size only. The distinguishing features of Rambler design during the past several years, such as offset crank shaft, large wheels, straight line drive, Rambler spare wheel and engine accessibility, have been retained in the new models. Two of the chassis have 5x5½ inch engines, rated at 45 horse power, and the chassis differ only in the length of wheel base and the size of tires.

Model 55, the seven passenger touring car, has a 45 horse power engine, a wheel base of 122 inches, 36 inch wheels and 41/2 inch tires. The equipment of this model includes a magneto, gas lamps, a Prest-O-Lite tank, electric side and tail lamps, and a 6 volt, 80 ampere hour storage battery. The same chassis with 5 inch tires is used for the seven passenger limousine. Model 54 is provided as a five passenger touring car or a four passenger close coupled car, and the same equipment is furnished with it as with Model 55. It is fitted with a 45 horse power engine, and has a wheel base of 117 inches and 36x4 inch wheels. Model 53 is another five passenger touring car, and is almost a duplicate of last year's Model 44. It has a 41/2x41/2 engine rated at 34 horse power, and the equipment includes magneto and lamps. The following

RAMBLER FIFTY-THREE.

description applies to both Models 55 and 54.

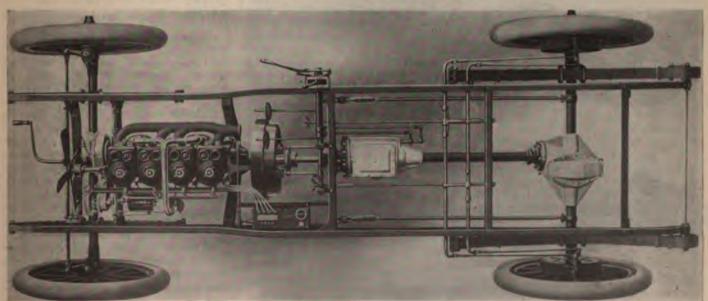

The engine, as the photograph shows, is of the same type as used in Models 44 and 34 Ramblers of the past two seasons. The valves overhang all on one sides and the crank shaft is offset 25 per cent. of the piston stroke. The crank case is of the barrel type with an opening 23x8 inches on the side for inspection and adjustment. A wedge type of bearing adjustable from the side, shown in the illustration, makes possible easier and more perfect adjustment from the side than can be accomplished by the bolt method. In the 1910 model the pump has been moved to a position forward of the cam gear case. This change is to provide for a more accessible magneto location. It is now located on an extension of the pump shaft just back of the cam gears. It can be very easily reached for both inspection and adjustment. A combined shield and oil gutter attached to the crank case at the rear of the flywheel and main bearing returns all surplus oil that may work through this bearing back to the crank case. This eliminates the possibility of its dropping on to the flywheel.

and being thrown on to the other mechan-

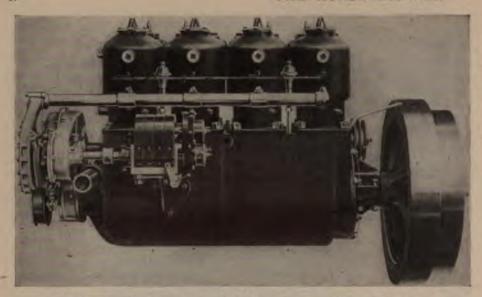

In Models 55 and 54 chassis the clutch has been changed from the cone type to the internal expanding type. This eliminates end thrust on the crank shaft, and its design is such that it exerts the greatest pressure when fully engaged. With the average clutch the spring is expanded when the clutch is engaged so that it then exerts the least instead of maximum pressure. This clutch has been very thoroughly tested on a number of different Ramblers, and it has been found to be ideal in operation. It is said to engage very gradually, hold positively, and disengage instantly.

The only change in the transmission is at the roller bearing, which carries the forward end of the main drive shaft. This is a hinged bearing with a dowel fastening, retained in a steel case, and provided with adequate means to compensate for all end thrust.

The rear axle continues of the semifloating type, but the drive shafts are larger, and a new method is used for securing the wheels. On the Rambler drive shafts the differential gear is upset on the end of the

RAMBLER FIFTY-FOUR CHASSIS.

RAMBLER FIFTY-FIVE AND FIFTY-FOUR ENGINE, MAGNETO SIDE.

shaft, making the drive gear and axle integral. Now, the wheel end of the shaft is also upset. This enlarged end is squared and tapered for the forged wheel hub. This method of upsetting or enlarging the shaft before squaring it makes it strongest at this point, whereas otherwise the metal removed by squaring would weaken it.

The springs are of the triple action type, but somewhat modified in design from those of last year. They are straighter, and the second leaf is longer, extending into the bend of the top leaf so as to support it.

The steering continues of the screw and nut type, but the nut has been lengthened to increase the wearing surface, and a ball thrust bearing has been added with better provision for adjustment.

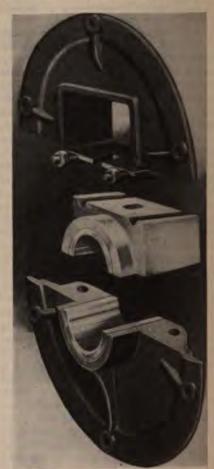

A neat pressed steel bracket supports the bonnet at the dash. The strap is done away with, and the bonnet is held down by convenient spring clamps. Particular attention has been paid to the guards; they are wider, heavier, better braced, convexed both to strengthen them and improve the appearance, and their outline is much more graceful. The front guard follows the radius of the wheel, while the rear guard extends straight back with the body lines. A neat filler strip projects from nearly the top of the frame to the running board, entirely covering the running board supports. Four of these supports are provided for the larger and wider running board now used. This board is aluminum covered.

The changes in the bodies apply alike to

THE NEW RAMBLER FIFTY-FIVE, FIFTY-FOUR, AND FIFTY-THREE REAR AXLE SHAFT, ROLLER BEARING, SLEEVE AND CASE AND END OF AXLE TUBE.

both models. The most important change is a lower position of the seats. This adds to the comfort of the passengers, and improves the appearance. More room is provided between the front seat and the pedals. The tonneau floor is countersunk between the frame channels, providing plenty of room even with the lowered seat. Above the frame channels the tonneau is widened. In the seven passenger job ample room is provided to pass between the two extra chairs when they are occupied. These

FIFTY-FIVE ENGINE BEARING, WIDE TYPE AND ADJUSTMENT.

bodies are very richly upholstered with hand buffed leather, curled hair and deep springs. Deeper springs and more and better hair are used than heretofore, adding greatly to the riding qualities.

Although Model 53 is a smaller car, it can hardly be called a small car, particularly in power. With 41/2x41/2 cylinders the engine delivers 34 actual horse power by dynamometer test. The wheel base is 108 inches, the wheels are 36 inches, and the tires are 31/2 inches. Four inch rear tires are furnished, if desired, at \$20 extra. The description of Models 55 and 54, relating to the pump and magneto locations, the oil shield and gutter, transmission bearing and rear axle, applies also to this model. Practically the only other important change from its predecessor is in the rear springs. They are the full elliptic Rambler type, with involute ends. These springs have been used for two seasons on other Rambler models.

### National 1910 Models.

Three models will be manufactured by the National Motor Vehicle Company, of Indianapolis, for 1910. In addition to the former models a new four cylinder, 40 horse power, five passenger car will be produced to sell at \$2,500. The several models will be known as the "National 60," which is a six cylinder car with 5 inch bore and 5 inch stroke motor; the "National 50," with six cylinder, 4½ inch bore and 4¾ inch stroke motor, and the new "National 40" four cylinder car. Since the new "40" embodies all the improvements which have been made in the older models, only it will be dealt with here.

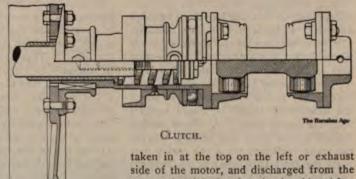

The cylinders are cast in pairs, and are of 5 inch bore and 516 inch stroke. They are not cast with a common cylinder wall in the centre as some twin cylinders are cast, but the cylinders are entirely separated, leaving a water space at the top and an air space between them at the bottom. In machining the cylinder castings they are first bored to within 25-1000 inch of the finished size, and are then placed in an annealing furnace, in which the temperature is gradually raised to 1,000° Fahr., and which is then allowed to gradually cool, the process occupying twenty-four hours. They are then returned to the inspector, who tests them under cold water pressure, and if found in perfect condition they are sent to the machine room, where the valves are seated and the valve stem guides put in place. They are then ready for the cylinder grinder.

While the cylinder walls are being ground the cylinders are kept at an even temperature by means of hot water, and the dust is removed by air pressure from a blower. The cylinder is then again inspected, and the valve chamber caps are fitted. These valve chamber caps are in two pieces, and do not seat upon gaskets. The

lower portion of the valve chamber cap, the one into which the spark plugs are fitted, has a taper seat which conforms to a similar seat in the cylinder casting. These seats are of 45 degree angle, and are ground together in the same way the valve seats are ground in. This lower portion is held in place by a threaded ring similar to the thread on an ordinary valve chamber cap.

The nickel steel valves are of 2% inches diameter, with 3% inch lift, and 15-32 inch stems, with hardened ends to reduce wear from the action of the valve lifters. The lower ends of the stems are slotted to receive a flat key for holding the valve spring retaining cup. This retaining cup is turned with a shoulder which fits inside the valve springs, holding it in position.

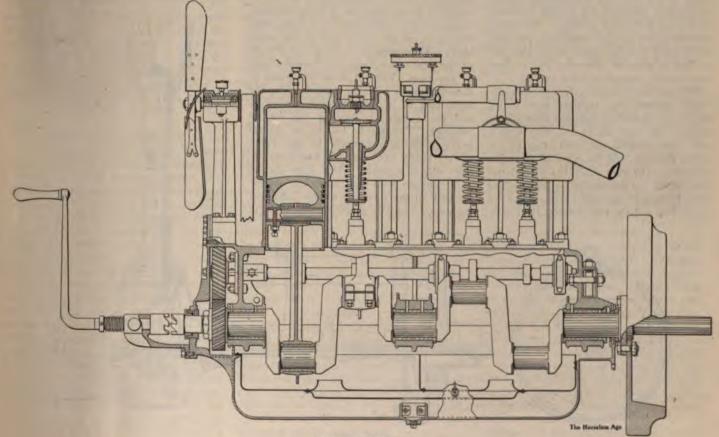

The water jackets are large, covering the whole cylinder head. The cooling water is

taken in at the top on the left or exhaust side of the motor, and discharged from the top on the right hand or intake side. After the motor has been completely assembled it is placed on a stand, the cylinders are filled with clear oil, and the engine is run by belt for several hours to lap and polish the pistons, piston rings and cylinder walls.

The pistons are long and subjected to the same annealing process as the cylinders. They have four compression rings at the top, and two oil grooves at the bottom. These grooves are 1-64 inch deep and ½ inch wide. The pistons are slightly oval and highly polished, to prevent the sticking of carbon as much as possible All pistons are machined to within an ounce of a standard weight, as are all reciprocating parts. The piston pin is a hollow, nickel steel pin, hardened and ground, and held in place by a set screw and lock nut. The hole in the pin is large, and the set screw seats in a spot hole on the top side of the pin.

The crank shaft is a solid one piece drop

NATIONAL MOTOR.

forging of 40 point carbon steel, hardened and ground to size. It has three bearings lined with white bronze die cast bushings. The main bearings of the crank shaft are all 21/2 inches in diameter, the rear bearing next to the flywheel being 45% inches long, the centre bearing 334 inches, and the front bearing 31/4 inches. The flange to which the flywheel is bolted is forged integral with the crank shaft. A thrust washer bearing on the front end bearing between the crank shaft and the crank casing prevents the shaft from wearing the bearings endwise from clutch spring pressure. The crank shaft gear is fitted to a taper bearing with a Woodruff key, and held in position by a lock nut. The crank shaft gear and cam shaft gears are of the helical type.

The connecting rods are I section drop forgings, and of the same material as the crank shafts. A cup is milled into the top of the connecting rod to catch oil splashed into the top of the piston. This helps supply the piston pin with lubricant. The top bushing is of phosphor bronze, 25% inches long. The lower bushing is of white bronze of 118 inches in diameter and 3 inches long. The lower bearings are of the marine type, the cap being held in place by four studs. At the lowest point on the cap is located a small oil spoon, which dips into the oil and causes the splash. At no time does the connecting rod itself dip into the oil.

The intake is located on the right hand side of the motor, and has a T shaped manifold at the centre of which is attached a Schebler carburetor. The exhaust is located on the left side, and directly beneath the exhaust manifold are located the water circulating pump and magneto. The intake manifold, the exhaust manifold, the inlet water pipe, and the outlet water pipe are all held in place by four nuts, and all have taper points, no packing being used.

The inlet and exhaust valves are mechanically operated by separate cam shafts, which are located on opposite sides of the motor. The cam shafts are drop forged, with cams integral, the shaft being of 1½ inches diameter, and the cams of 1½ inches diameter. The cam shaft has three bearings, which are adjustable for wear. The front bearing is 3½ inches long, the centre 2¾ inches, and the rear bearing 2¾ inches.

The cam shaft gears are of manganese bronze, and are secured to the shaft flange by four 36 inch hardened dowel pins, and a lock washer and nut on the end of the cam shaft. These are blind pins, and it is necessary to remove the gear in order to know that they are there.

The valves are actuated by roller lifters of quite original design. The lifters are fitted with a coiled spring to take up the slack in the mechanism and obviate noise. At the top of the lifter guide is a small stuffing box to prevent dirt from getting into the crank case around the lifter, or oil getting out. The valve lifter guide is made large enough to admit of a small steel shell being pressed over the roller end. This shell is slotted on both sides; the roller pin is milled flat on both ends, and when assembled the slots act as guides to prevent the roller turning out of parallel with the cam. The rollers are hardened and ground, as are also the roller pins. The top ends of the lifters are drilled and tapped to receive the valve adjusting screw. which is held fast by lock nuts. The valve stem adjusting screws are of nickel steel, hardened.

The crank case is in two pieces, or really three, if the gear compartment cover is counted. The gear compartment is oil tight and integral with the upper half of the case. A stuffing box is used on the starting crank end of the crank shaft to retain the oil. The upper half contains all the bearings, the lower half being separate and independent in every way The bottom of the crank case is a separate compartment holding several gallons of oil, which is forced into the various compartments of the upper case by a gear pump driven off of the lower end of the timer shaft. The pump is let into the bottom of the crank case, where it forms a part of the case. The oil from the pump is forced through a single sight feed on the dash, part of it going through the gears, and the remainder flooding the various bearings. The oil is led to its several bearings through channels in the crank case. There are vertical standpipes in each splash chamber, which keep the oil at a constant level and carry the surplus oil back to the reservoir at the bottom of

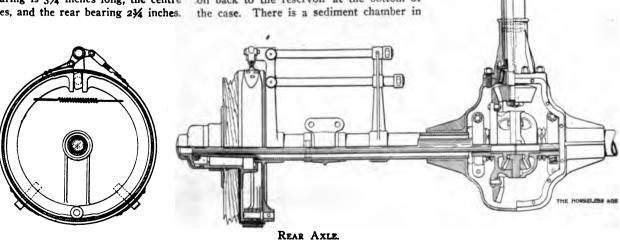

the centre of the oil reservoir, which collects the dirt or impurities in the oil before it is again used. This system is automatic, and requires no adjustment or attention other than to see that there is oil in the reservoir.

A large centrifugal water pump is gear driven from the exhaust cam shaft gear and is used in connection with a cellular radiator. The system holds 5½ gallons of water. A ball bearing fan is located back of the radiator, but independent of the radiator and mounted on top of the gear compartment. An eccentric bushing is used in the top of the fan bracket for the adjustment of the 1½ inch flat belt, which drives the fan at two and one-half times the motor speed.

Immediately back of the pump, and driven by the same shaft through a flexible joint, is located the Bosch magneto. On the opposite side in the centre, and driven by bevel gears from the intake cam shaft, is located the combined timer and distributor. Two separate and distinct ignition systems are used, with separate spark plugs. The spark plugs are located in the valve chamber caps, the battery set being located over the exhaust chambers and the magneto set over the intake chambers. The storage battery is carried in a water tight box on the running board on the right side of car.

The flywheel is of cast iron, 19 inches in diameter, and weighing 105 pounds.

The carburetor is fitted with a foot accelerator, and the inlet manifold with an auxiliary air inlet which is adjustable from underneath the steering wheel on the

steering column. A bleeder pipe is located on the top of the crank case, between the cylinders, to relieve crank case compression.

The motors are run light on the testing stand for twelve hours and under dynamo load with lights for six hours, cards and load readings being taken at different speeds.

A leather faced cone clutch is used, supported on the flywheel end of the crank shaft. The clutch is 15 inches in diameter with 234 inches face. Underneath the leather facing are eight flat springs I inch wide and 3 inches long, which gradually take up the load when engaging. A brake is arranged on the clutch pedal releasing yoke, which presses on a small drum on the clutch spring housing and stops the clutch from revolving when it is released, insuring quiet shifting of the gears. A heavy spiral spring keeps the clutch engaged until released by the clutch pedal or the application of the foot brake. A ball thrust clutch releasing collar is used. A ball thrust is also used at the outer end of the clutch spring. The clutch spring is held in place by a bolt screwed into the end of the crank shaft. This bolt is hollow and split on the thread end, and is locked by a taper bolt running through and tightened by a nut on the outside. The clutch may be removed from the car without disturbing the transmission or motor, owing to the use of a sliding double universal joint between the clutch and the transmission. A selective type transmission is used, with three speeds forward and reverse, with a direct drive on the high speed. Timken roller bearings are used on both ends of each shaft. The gears are of 31/2 per cent, nickel steel, case hardened and drawn in oil. Each of the two sliding sets is shifted by separate shafts operated by a single lever at the top of the gear casing. The gear casing is of aluminum and is located directly beneath the floor boards at the driver's feet. The speed lever works in an H slot with a lock to prevent going into reverse when shifting from a low gear into a higher, or vice

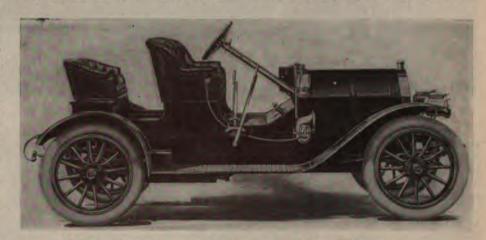

The propeller shaft is connected to the main transmission shaft by an enclosed sliding universal joint, which is lubricated by oil forced from the transmission case through a spiral groove on the main transmission shaft. The torque strains are taken by a swivel device bolted to the centre cross member of the main frame and supporting the universal joint, the propeller shaft and the tube in which the shaft is enclosed. Within this tube, which is attached to the bridge casing on the rear axle, the propeller shaft revolves on two Timken roller bearings, one at the forward end and one at the rear end next to the bevel driving pinion. These two bearings take up the end thrust also. Keyed to the rear end of the propeller shaft and secured by a lock nut is the hardened nickel steel main drive pinion, which engages the large hardened nickel steel driving gear. All the weight and load of the car is carried on heavy gauge steel axle tubes fitted into a

cast steel bridge casing centrally located between the rear wheels.

The differential gear, which is of bevel gear and pinion type, is mounted on Timken roller bearings, which allow for endwise adjustment. The inner axles are squared at the ends and fit into squared holes in the differential bevel gears on one end and the hub clutch plates on the other. The dust caps hold the clutch plates in place and make the axle oil tight. The rear wheels

Mitchell 1910 Models.

The Mitchell Motor Car Company, of Racine, Wis., have made no radical changes in the mechanical design of their cars for 1910, but they have completely modified their policy with respect to types. Where last year they produced motors of three-different cylinder sizes, they are this year using only one size of cylinder, of 4½ inch bore by 5 inch stroke. They have also put out a six cylinder model, which is

MITCHELL MODEL R-FOUR CYLINDER, 30-35 HORSE POWER ROADSTER.

run on Timken roller bearings on the axle tube end.

The front axle is a solid one piece drop forging of I section, with spring saddles forged integral. The front wheels run on Timken roller bearings.

The spark and throttle control levers are located on a stationary quadrant on top of the 18 inch steering wheel. An accelerator pedal is located at the left of the brake pedal. The inside hand lever at the driver's right operates the emergency brakes, the outside hand lever working in an H slot shifts the transmission gears. The left pedal operates the clutch; the right pedal applies the brakes.

The brakes are of the internal expanding and the external controlling types, respectively, both operating on the rear wheel brake drums. The internal brakes, operated by pedal, are the service brakes, and have a bronze to steel friction surface. The external emergency brakes are composition lined and operated by the hand lever.

The frame is of pressed nickel steel of channel section and is dropped at the rear. Semi-elliptic springs, 40 inches long, 2 inches wide and with six leaves, are used in front, and three-quarter scroll elliptic springs, 48 inches long, 2 inches wide and with six leaves, are used at the rear. The wheel base is 122 inches.

A five passenger body of straight line design is fitted. It is long and affords plenty of room between the front seat and the dash, with the steering column at an easy rake. The steering gear is of the worm and sector type. The gasoline capacity is 17 gallons. Thirty-six by four inch tires are fitted. The color is either red or green and the upholstering black.

an innovation for them. Their 1910 line will consist of three models, as follows: Model R, four cylinder, 30-35 horse power roadster,

Model T, four cylinder, 30-35 horse power, five

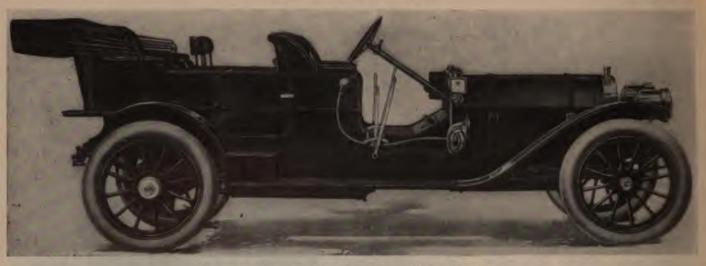

passenger touring car, \$1,350.

Model S, six cylinder, 50 horse power, seven passenger touring car, \$2,000.

The four cylinder touring car and roadster have the same specifications, except that there is one less leaf in the springs of the roadster, the rear axle is semi-floating instead of full floating, and the brake drums at 10¾ inches in diameter instead of 14 inches.

The cylinders are this year cast in pairs, instead of singly, as last year, and there are three bearings on the crank shaft of the four cylinder motor (instead of five) and five bearings on the crank shaft of the six cylinder motor. The general arrangement of, the valves remains the same, the exhaust valves being located in side pockets on the left hand side, and the inlets in dome-shaped extensions of the cylinders. The inlet valves are placed in cages. The cam gear and valve mechanism has been redesigned, and is now claimed to be absolutely noiseless in operation. The magneto and carburetor have been arranged differently on the motor, the magneto being now on the left hand or exhaust valve side. and the carburetor on the right hand side. The Splitdorf dual ignition system is used. A centrifugal pump has been substituted for the gear pump used last year, and is placed in line with the magneto armature and driven from the same gear. The cam shaft gearing is enclosed in a separate housing divided through the centres of the crank shaft and cam shaft.

Instead of the bracket secured to the

MITCHELL MODEL S, SIX CYLINDER, 50 HORSE POWER CAR.

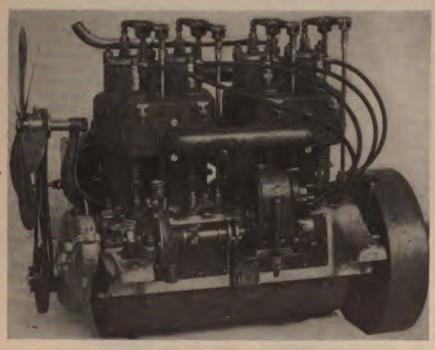

crank case by two of the retaining bolts of the forward cylinder, which was used in last year's models for supporting the radiator fan, a small bracket is now used which is secured directly to the forward cylinder casting. A mechanical lubricator is located on the right hand side of the forward pair of cylinders, and is driven by a rounl belt from the crank shaft.

The clutch is of the leather faced cone type, with springs under the leather for gradual engagement, the same as in former years. A decided change has been made in the arrangement of the transmission and rear axle drive. The transmission case and propeller shaft housing together form a torque member, which is supported from a cross member of the frame about midway between the front and rear axles. The change gear is connected with the clutch through a universal joint, and this is the only universal used in the driving mechanism. The transmission is of the

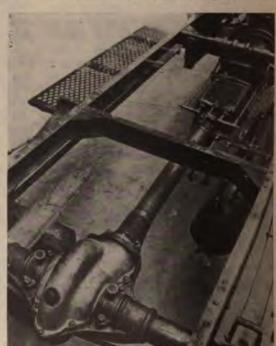

sliding type and is operated selectively. The two shafts are arranged one above the other. The main shaft is carried in ball bearings, and the lay shaft in Hyatt roller bearings, instead of roller bearings being used throughout, as last year. The H quadrant for the selective operation of the gear is located in front of the gear box, instead of at the side of the frame, as is customary. Since the propeller shaft housing and gear case serve as torsion members, no special torsion rod is required, but two radius rods extend from the rear axle to the side frames at a point near the suspension of the driving unit. An option is given on two rear axle reductions, viz., 31/4 to 1 and 33/4 to 1. The rear axle is fitted with ball thrust and radial bearings. The front axle is an I section drop forging made in a single piece without a weld.

The frame is of pressed steel, the section being 4 inches high by 1½ inches wide. It has three cross members and is provided with heavy gusset plates at the corners. The frame of the six cylinder car has a reinforcing plate in the channel. It is slightly inswept at the forward end. The frame is supported by three-quarter elliptic scroll springs in the rear in the four cylinder models, and platform springs in the six cylinder model. The front springs of all models are semi-elliptic, being 41 inches long by 2 inches wide. The three-quarter elliptic springs of the four cylinder models are 44x2¼ inches, while the platform springs of the six cylinder model consist of 45x2¼ inch side members and a 37x2¼ inch cross member.

The wheels have been increased in size. They have twelve spokes and are fitted with ball bearings and stamped hub caps. On the six cylinder model the front wheels are fitted with double annular ball bearings. The steering is by an irreversible worm and worm gear, so arranged that the gear can be shifted after it has worn at one place. The

Models R and T Engines, 30-35 Horse Power.

MITCHELL MODEL S CHASSIS, REAR VIEW,

wheel base is 100 inches for the roadster. 112 inches for the four cylinder touring car and 130 inches for the six cylinder touring car. The tread is the standard 56 inch, but a 60 inch tread is optional. The tire equipment is as follows: Roadster, 32x31/2 inch; four cylinder touring car, 34x31/2 inch; six cylinder touring car, 36x4 inch. The sod pan, which extends under the engine and back to the transmission, is held in place by spring hooks, which makes it readily detachable. On the four cylinder cars 16 inch steering wheels are fitted which have a natural finish. The six cylinder car has an 18 inch steering wheel of the same finish. The spark and throttle levers move on sectors below the wheel. The control devices are arranged according to standard practice, there being the usual outside brake and change gear levers, and clutch and brake

Waverley 1910 Models.

The leader among 1910 Waverley models is their new four passenger brougham Model 75-C, designed on lines similar to the four passenger coupé put out in 1909, but differing in some important particulars. Thus the car is 5 inches longer (911/2 inches), with a wheel base of 79 inches and a width of seat of 44 inches. The wheels are 2 inches larger, fitted with 32x31/2 inch tires front and rear. The springs are full elliptic front and rear, giving a much easier riding car. The battery is two cells larger (thirtytwo cells of eleven or thirteen plate), arranged with twelve cells in front and twenty cells in rear compartment.

The controller is of special Waverley design, which is claimed not to waste current and to be absolutely dependable.

Model 70-C Waverley coupé differs from Model 75-C chiefly in the form and size of the top, which accommodates but two passengers. Thirty-two inch wheels are used on this model, as well as on the new Waverley cars. Tires, however, differ from those on 75-C, being 32x3 inch front and 32x3½ rear, solid or pneumatic. A thirty cell, eleven plate battery furnishes the current, which is converted into power by the special Waverley motor used on all 1910 models, and transmitted to the wheels by the Type "K" driving system, described above. The controller is also the same pattern.

Model 76, the new Waverley victoriaphaeton, differs materially from the old type victoria of last year's make. The dimensions of the body are the same as those of Models 75-C and 70-C, and the

MODEL 75-C, WAVERLEY FOUR PASSENGER BROUGHAM.

MODEL 74, WAVERLEY STANHOPE, VICTORIA TOP.

pedals on opposite sides of the steering column, as well as the Mitchell corrugated arc accelerator pedal. The running boards are of pressed steel. Options are given on the following types of bodies for the different models: Model R, roadster body with either rumble seat, surrey seat or runabout deck; Model T, four passenger close coupled body or five pasenger touring body; Model S, four passenger close coupled road ster or seven passenger touring body. Special efforts have been made to produce bodies of attractive appearance, and the contour of the radiator has been materially changed with this object in view. All models are equipped with steel tool boxes, adjustable headlight brackets and tail oil lamps, a horn and a complete set of tools. including a jack.

The firm of D. P. Nichols, of Boston, have gone into the building of taxicabs and limousine bodies quite extensively. They are just completing an order for seventy-five taxi bodies for De Dion chasses for the New York Transportation Company and another for twenty-five limousines for a large importing firm.

It consists of a core, on which are assembled blades of various widths engaging in fingers to the frame of the controller. This system of knife blade contacts permits the passing from one speed to another without breaking contact. Four forward and four reverse speeds are available, and the circuit is never broken after the power is once applied. The controller is said to be non-arcing.

In the new Waverley driving system the motor is wholly attached to the body and has both the driving parts entirely encased and running in a continuous bath of oil. The motor and flexible gear case are combined in a single unit and assembled on crosspieces attached to the body frame. These are separated from the body by rubber cushions intended to overcome the effects of vibration. The power is transmitted by a flexible gear, a shaft parallel with the axle and a small herringbone gear on the rear axle. The wheel bearings are Timken roller bearings, but six Hess-Bright ball bearings are used on the gear and pinion shafts, all thoroughly protected from dust and carriage is interchangeable with these by the addition of a brougham or coupé top. For summer service a full leather victoria or buggy top is used. The old form of combined dash and fender has been changed. The increased length of body and wheel base gives an easier riding motion to the seat, and room is provided for a disappearing child's seat. Thirty-two inch wheels and full elliptic springs make this a particularly easy riding carriage. All the above models use the patented Waverley drop-sill.

The chief novelty of the season in Waverley electrics will be the new road-ster, Model 78, a gasoline type of gentleman's runabout with a folding rumble seat, large battery disposed in a long front hood, and an estimated speed of 25 miles an hour. As the first of these cars is not yet completed it is too early to give full specifications.

Model 74 Waverley stanhope is the same car as last year. The use of 32 inch wheels with solid tires is recommended on this car, although pneumatics are provided when desired. This is essentially a business or professional man's car.

# Pope-Hartford Automobiles for

The new model of the Pope Manufacturing Company for 1910 is known as the Model T. It embodies numerous changes over last year's models, which affect the vital points in the mechanical construction as well as adding to the beauty of the car. In the 1910 model the wheel base has been increased from 114 inches to 118 inches, and the wheels have been increased from 34 inches to 36 inches. Four inch tires are the standard equipment, while 4½ inch tires are put on the rear wheels of the seven passenger, limousine and landaulet.

The engine has four cylinders, which are cast in pairs, and it develops 40 horse power. This power is claimed to be sufficient to drive the car over any grades on the high gear that can be taken by the highest powered and highest priced cars, and to make over 60 miles on the level. The valves are all interchangeable, are located in the cylinder heads and are mechanically operated.

The transmission is of the selective type, with three speeds forward and reverse. The gears are made of chrome-nickel steel, with the ends of the teeth beveled by a new process so that the changing from one gear to another is accompanied by scarcely any noise. The clutch is of the inverted cone type, faced with leather, with cork inserts.

The rear axle is the full floating type, with special alloy steel shafts. The rear wheels run on roller bearings on an outside tube, which serves as a housing for the axle proper. In this type it is possible to remove the axle shafts and the entire differential construction with the car standing on its own wheels.

One of the most important improvements is in the lubricating system. A mechanical oiler is mounted on the crank case, and in addition to the regular pumps used in the 1909 models there are a large suction pump

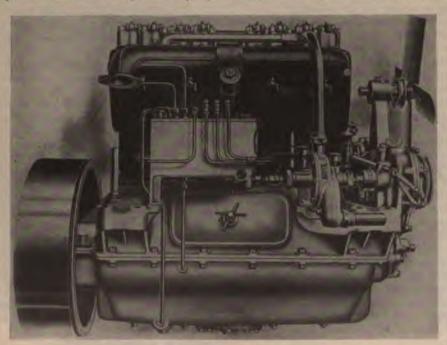

1910 POPE-HARTFORD MODEL T, TOURING CAR.

and a standpipe that permits the oil on reaching the level of the pipe to run back

STEERING KNUCKLE AND CONNECTIONS.

into the crank case. Underneath and cast integral with the crank case is an oil reser-

POPE-HARTFORD MOTOR,

voir. The crank case proper is provided with standpipes fitted with gauze strainers, making it possible to maintain at all times a predetermined oil level in the crank case. Oil is pumped from the oiler to the cylinders, and the main bearings are lubricated by splash from the crank case. The rear axle is lubricated by splash, and has pet cocks fitted in the axle case to hold the proper level of oil.

The transmission is lubricated by splash, and all other parts are provided with grease cups. The oiling system is said to require attention only every 800 or 900 miles.

A new style torque rod has been adopted. This is of trussed tubular construction, with its rear end pivoted on the rear axle case and the front end fitted with spring buffers and attached to a special cross member of the frame. The rear spring seats swivel on the rear axle, and the rear springs are shackled at both ends. The drive is taken by two adjustable radius rods, one at each end of the axle. The rear end swivels on the rear axle tubing, and the front end, consisting of an adjustable ball and socket joint, is attached to a special bracket located on the frame.

Improvements have also been made in the design and construction of the bodies. The straight line effect has been strictly adhered to, thus doing away with many of the little crevices and pockets that formerly caught and held so much dust and dirt and were so hard to keep clean. The different bodies are all built on the same chassis, the only difference being made in the roadster. Here the engine is set a few inches further back in the frame. This makes a little longer and "smarter" hood. The steering column is tilted more than in the other models, to bring the steering wheel comfortably into the reach of the driver. The seats also are a trifle lower. The prices of the different models are as follows: Pony tonneau or roadster, \$2,750; seven passenger touring car, \$3,000; limousine or landaulet, \$3,750.

The Willys-Overland Company have started work on a five story, 600x100 feet, addition to their Toledo, Ohio, plant, which will be used for the finishing department. The building is to be ready for occupancy in forty days.

W TORSION ROD AND RADIUS ROD OF POPE-HARTFORD.

he Delco Ignition System.

Dayton Engineering Laboratories any, Dayton, Ohio, have brought out tery ignition system which presents points of decided novelty.

system is essentially a single make eak arrangement with individual coils aster contact breaking device, an ordiommutator being used to time the ignitial individual solutions. It is so arranged that it should be lingly economical of current, and it med that it will ignite the motor of a cylinder car for 2,000 miles of runfrom a battery of six dry cells of the ry size. Special attention has been making the apparatus free from arcthe contacts, so that adjustments may required, and the statement is made here should be no need of attention kind until after 20,000 miles of ser-

apparatus comprises three essential-the coil box, the relay case (containe make and break), and the switch lition to these is the timer or compr, which may be of any good make coil box is of steel armored constructed made perfectly tight, so as to be oil and water proof. It contains the ed number of simple, non-vibrating four in the case of a four cylinder

The four high tension terminals out of the top of the box, through conical insulating bushings, and the adividual primary binding posts and amon primary connection are mountent the under side. Between each pair ondary posts is a grounded brass ted with discharge terminals, which safety spark gaps for the coils and to protect the same against breaking in case of an accidental detaching of tension cable from its plug. By go with a screwdriver from the brass the high tension terminal, any cylnay be cut out when testing is being

performed. This coil box is intended to be mounted under the hood directly upon the motor, on brackets arising from it, and the secondary cables required are thus very short.

The circuit breaker or controlling relay is also housed in a pressed steel case of cylindrical shape, and is always mounted under the hood, being held by the same brackets which support the coil box or by a special bracket fastened to the front of the dash. Its function will be explained later.

It is a characteristic of this system that no

part thereof, except the switch, is mounted upon the face of the dashboard, and a very

CONTROLLING RELAY.

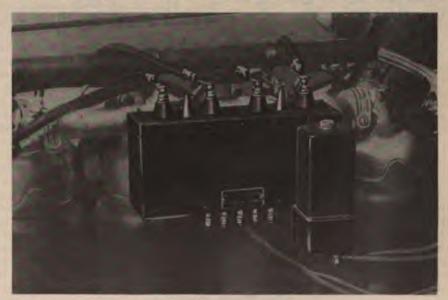

neat and unobtrusive arrangement is the result. The switchbox is entirely of metal

and the mechanism is very thoroughly insulated and provided with substantial nontarnishing contacts. It is of the swinging lever type and is made ruggedly enough to be safely operated by the foot. The lever has three positions—"battery," "magneto" and "off." In the upper portion of the switchbox is a button which, when pressed in, causes the single break apparatus to act as a vibrator and furnish a continuous succession of sparks to the cylinder which is ready to fire. This button will not remain pressed in unless the switch is in the "off" position; but if it is the button will hold the contact, but will immediately fly out and cut off the vibrating action when the switch is thrown either to the regular battery side or to the magneto position. In starting from the seat the button may be pressed with the foot, and if the motor starts the switch may be kicked over to either side, dependent upon which system is to be used. the button releasing and the vibrating action immediately ceasing thereupon. In case the motor does not "spark up" the button will remain pushed in and the motor may be cranked in the usual manner, there being a succession of sparks so long as the timer is in contact. When the motor is started in this manner a kick of the switch to one side or the other terminates the vibrating action of the make and break.

A key is furnished which locks the switch so that neither the button nor the lever can be operated, and the lock is so arranged that it cannot be operated by any other means than its own key.

Starting can readily be accomplished by means of the single spark normally furnished by the system, but the spark from the vibrating break is more effective when the motor is cold.

The system is connected up in a manner similar to the ordinary master vibrator system with multiple coils, the free sides of each coil unit primary being connected to a segment of the timer, and the common terminal of the coil primaries being attached

DELCO IGNITION SYSTEM ATTACHED TO FOUR CYLINDER MOTOR.

to one side of the battery. The other side of the battery goes through the pair of master contacts in the controlling relay case, through the switch and to ground.

The main peculiarity of the system lies in the fact that the contacts controlling this circuit are operated by a relay magnet, which is separate electrically from this main circuit, but which is in a circuit also including the timer and the battery.

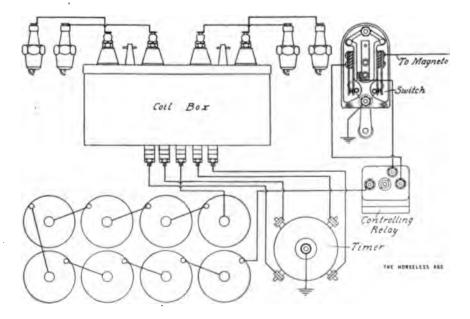

The relay magnet is of high electrical resistance, and passes but a minute current. It is mounted in its case with its core vertical, and acts upon a light armature pivoted horizontally above it. The other arm of the armature element is vertical, the arrangement being in bell crank form, and this arm acts upon the main circuit contacts, which are of platino-iridium and normally in contact under a delicate spring tension. When the relay armature attracts its armature these contacts are separated and the main circuit through the battery timer and coil is interrupted. When the relay magnet is de-energized the spring of the contacts brings them together again. The only adjustment provided is a movable ratchet toothed piece at the upper end of the magnet core, which determines the pressure between the contacts, and this, it is stated, should require no adjustment during the life of the car upon which it is used. A well proportioned condenser is doubtless used around the contact points of the make and break, and it is a fact that absolutely no spark can be observed at the points when the engine is running.

The action of the arrangement is as follows: Supposing the timer not to be in contact, the relay magnet is not energized and the circuit at the controlling points is closed, but no current passes in the system on account of the break at the timer. When the timer touches a segment the circuit through one of the coils, the battery and

the controlling contacts is closed, but the circuit is also closed through the branch circuit, including the timer, battery and relay magnet. The relay magnet is at once energized, it draws down its armature and opens the controlling contacts, breaking the circuit through the coil and producing a spark of high intensity. On account of the high winding of the relay magnet sufficient time elapses before the break to allow for the proper building up of the coil. Although the main circuit is thus broken, the relay magnet circuit is held completed and the controlling contacts are held separated until the timer contact leaves the segment, when the relay circuit is also broken and the initial conditions are restored; thus the main circuit is closed only long enough at each ignition adequately to saturate the spark coil which may be in circuit, and the current consumption is thus reduced to a minimum, which is stated to be 0.15 or 0.16 ampere at 1,000 engine revolutions. As the duration of the contact required by each ignition is constant, depending upon the electrical characteristics of the relay magnet, the total consumption of energy per unit of time is almost directly as the number of ignitions or the engine speed. Not over 0.04 or 0.05 ampere is said to be drawn from the battery at low engine speeds.

It is especially to be observed that the main ignition current is not broken at the timer, but at the controlling contacts, and the only current which the timer is called upon to rupture is the minute current which passes through the high resistance relay magnet. Burning of the timer brush and segment, which is the cause of most timer trouble, is thus eliminated.

This system is applicable to any car, and is estimated to operate with one-third the battery energy required by a good vibrating coil outfit.

DELCO WIRING DIAGRAM.

#### The Wico Igniter.

The Witherbee Igniter Company, of Springfield, Mass., whose New York office is located at 1876 Broadway, have entered the market with a novel ignition system.

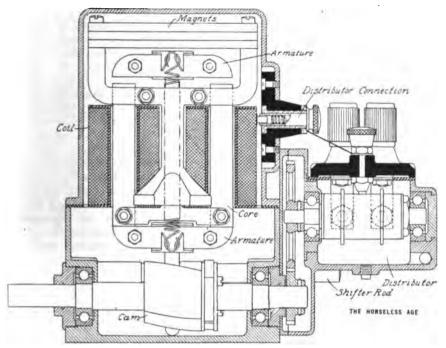

WICO IGNITER.

Their device, which is known as the Wico igniter, resembles a high tension magneto in many respects, but it has this advantage over the latter device, that the intensity of the spark generated is entirely independent of the speed at which the device is driven; consequently, a motor may be started by cranking slowly and need not be hurled around rapidly, as is generally required with magnetos. It is, however, not even necessary to crank the motor if there is any charge left in the cylinders, as a spark may be produced with this system by a simple back and forth movement of the ignition timing lever, and thus the motor started from the seat.

In the Wico igniter the necessary current is generated by mechanical means driven from the motor. Those who are familiar with high tension magnetos know that in these magnetos the current is produced in the secondary winding on the armature by suddenly short circuiting the primary winding and thus decreasing the lines of magnetic force passing through the secondary coil. The action in the Wico igniter is somewhat similar, the lines of magnetic force through the secondary coil being also suddenly decreased, but in a different manner than in the magneto.

Referring to the accompanying illustrations, it will be seen that the igniter is of somewhat similar form to a magneto and is encased in a metallic housing. As may be seen from the sectional view of the igniter, a set of permanent magnets is located in the upper portion of this housing. The magnetic circuit of these permanent magnets is ordinarily closed through soft iron pole pieces, the cores of a double high tension coil and an armature connecting the lower ends of these cores. The magnetic lines of the permanent magnets, therefore, normally pass from the north pole of these magnets through the pole piece connected thereto, through one of the cores of the double high tension coil, through the armature at the lower end of the two cores. and back through the other core and the pole pieces to the south pole of the magnets. Between the permanent magnets and

LONGITUDINAL SECTION.

the pole pieces thereof is located a movable armature, which is drawn toward the upper ends of the cores of the double coil by means of two long coiled springs. The movement of this armature is controlled by the coiled springs on the one hand and by a vertical rod on the other, which rod at its lower end bears on a cam carried on the driving shaft of the igniter. This cam is slidably arranged on the driving shaft and is provided with a groove which engages a shipper lever connected with the timing lever on the steering post. When the igniter shaft is rotated the cam will raise the movable armature through the intermediary of the armature rod, and after the highest point of the cam is reached the armature will quickly be drawn down onto the ends of the coil cores by the two coiled springs. The coils are then short circuited magnetically; the magnetic lines of the permanent magnets, instead of passing through the cores of the coils, return through the pole pieces and the movable armature. The sudden diminution of the magnetic flux through the coils induces a high voltage impulse in the coils, which latter are provided with only a fine wire winding. The cam surface is helical, and by shifting the cam along its shaft the spark can be produced at an earlier or later period; also, by shifting the cam to the limit of its motion in the direction of late firing, the armature is raised onto the shoulder, and by then moving the cam to the earlier firing position, the armature drops and thus generates a spark. In this manner the motor can be started on the switch (or perhaps it would be better to say on the timing lever) by means of this device.

One terminal of the double high tension coil is grounded, and the other one is led out through the wall of the casing by means of a thoroughly insulated connector plug. From this connector plug connection

is made to the central terminal of the high tension distributor. The latter is of the drum type, instead of the more common disc type. Its shaft is driven from the main shaft of the distributor by a half time reduction gear. The shaft carries a drum of insulating material to which are secured segmental contact vanes of hardened steel, which revolve in contact with hardened steel buttons in a bath of oil, by which means the central terminal is brought in contact successively with each of the four high tension distributor terminals (in the case of a four cylinder machine) from which connection is made to the spark plugs. Both the main shaft and the distributor shaft are mounted on annular ball bearings.

It will be observed that there is no electric circuit breaker used in connection with this device, consequently there is no need for a condenser to obviate sparking, and the need of adjustment is also obviated. The cam and the wearing surface of the armature bar are liberally dimensioned and carefully hardened, and they run in a bath of oil, so they may be safely counted upon to have a long life. The springs are said to be made of the highest grade of steel wire, and the tension under which they are operated is very small in proportion to the strength of the material. There are no moving wires in the system. All parts of the igniter are enclosed in a dust and water proof housing of aluminum. The igniter is entirely self-contained. The range of spark timing is limited only by the requirements of the motor to which the igniter is fitted. For four cylinder, four cycle motors the igniter runs at engine speed, and for two cylinder, four cycle motors at cam shaft speed. We understand that the device can be fitted to any make of car in place of a magneto, and can be furnished to run in either direction.

### New Locomobile Limousines.

The new 30 horse power chassis of the Locomobile Company of America for 1910 may be fitted with a limousine body, and a design has been evolved which is claimed to be specially handsome and commodious. This vehicle will accommodate six or seven persons, five of them inside, all of the inside passengers facing forward. Although the body is quite large the car can be readily handled in traffic, as it can be turned round in a 38 foot street without backing. While the car is particularly adapted for suburban work, it is claimed to have sufficient speed and power to make it suitable for touring. Closed cars may now be heated by means of the exhaust gases or by means of electric stoves, and it is even possible to prepare hot beverages in the car while on tour.

### Stoddard-Dayton Addition.

Inability to supply the demand for their cars during the past year has caused the Dayton Motor Car Company to add some 150,000 square feet of floor space. This is in the shape of a six story addition to their former six story building. Besides this building they have acquired and equipped a large foundry in which all their cylinder and other castings are made, as well as all aluminum, bronze and brass parts. The new building will be used partly as a machine room and partly for assembling; in fact, the various departments on the six floors of the original building will simply be spread out over the new space. This does not apply, however, to the body shop, which seems already to be adequate. When this building is completed, which will be within ten days, the company will operate their own drop forge room, in which will be forged their crank shafts, axles. gear blanks, lamp brackets, small rod ends, turnbuckles, etc.; their own complete foundry, their own body building shop, trim shop and paint shop, and their machine shop, in which their motors, transmissions, axles, steering gears, etc., are made.

In their drop forge plant they also make and temper their springs and treat all steel parts. A portion of the new building is given over to the immense frame presses, where all frames are formed and finished. A laboratory has recently been added for testing all materials, both before and after treatment.

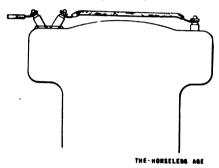

The number of automobiles in service in France at the end of 1908 is stated to have been 37,586, as compared with 31,286 at the end of 1907, and 26,262 at the end of 1906. The average horse power of the cars in use at the end of 1908 was 13.28, as compared with 5.06 at the end of 1899. Of the 37,586 vehicles in use last year 15,338 were used for business purposes and 22,252 for pleasure only.

# Two Simultaneous Sparks in a Cylinder.

Editor Horseless Age:

In a recent automobile publication I saw the exposition of a method of obtaining practically two simultaneous sparks in one cylinder by leading the high tension current from the distributor to a "single pole" spark plug, so set in the cap over the inlet valve that its sparking point would come in sufficiently close proximity to that of a

second "single pole" spark plug to provide a sparking gap. From the head of the second "single pole" plug a cable leads to an ordinary spark plug located over the exhaust valve, the action of the current being to jump the gap between the two "single pole" spark plugs and then pass over to the ordinary spark plug, thus creating two sparks in the cylinder—one over the inlet and one over the exhaust valvewhich, while not being precisely simultaneous, are practically so. The accompanying sketch will convey the matter in a more comprehensive manner than my description. In relation to this may I have your kind advice in the following, referring to a four cylinder, T head motor, 45/8x5 inch, the ignition of which is furnished by a low tension magneto with single step up coil:

- I. Is the method of creating two sparks, as above described, an efficient one in your opinion, and will it increase the power output of motor?
- 2. Will each of the two sparks possess the same intensity as would one spark delivered by the same magneto through a single "ordinary" spark plug?
- 3. Would there be a sufficient approach to synchronism of the two sparks to produce the advantages of firing a charge from two points at the same moment?
- 4. Is there any method other than that above outlined of obtaining simultaneous sparks in the same cylinder, where a magneto is the source of ignition?
- 5. Would it follow, as a consequence of firing a cylinder from opposite sides at the same moment, that a considerably less spark advance would be necessary to obtain maximum engine power than would be the case when operating with a single

spark? (This question is particularly pertinent to power output in hard pulling on grades with wide open throttle, when spark has to be retarded as engine speed decreases.)

6. Is a "single pole" spark plug made, and in what character of ignition service is it used?

P. I. B.

[The method described of producing two simultaneous sparks is the only possible one that we know of. We have no actual data of tests at hand, but we do not believe that the two sparks would have any appreciable effect upon the power output of the motor. This system of double sparks is sometimes used in the very largest of stationary engines.

If the spark gaps are of the same length in the two plugs in series, as in the case where only a single plug is used, then the intensity of each spark for a certain speed of revolution of the magneto will be somewhat less.

The two sparks occur absolutely at the same time, so far as practical considerations go.

We do not know of any other method of producing two simultaneous sparks in the same cylinder with an ordinary magneto without making some changes in the system. If the coil of the magneto were altered so that both high tension terminals are insulated instead of one terminal being grounded, then you could use two ordinary spark plugs to produce two simultaneous sparks, one high tension lead on the coil being connected to the central terminal of one plug and the other high tension lead to the central terminal of the other plug. The spark would then jump from the central terminal to the shell in the first plug, and from the shell to the central terminal in the last plug.

We do not believe that the production of two simultaneous sparks would have any appreciable effect upon the spark advance required. It was formerly thought that the spark advance was required because it takes the charge an appreciable time to burn, and as the time available is smaller when the engine runs at high speed, the charge must then be fired at an earlier period. It is now known, however, that the chief reason for the necessity of advancing the spark is that the vibrator in vibrator systems requires a fixed time to act, and this corresponds to a larger angle of crank motion when the engine runs at high speed than when it runs at slow speed. With mechanically operated make and break devices as furnished with high tension magnetos very little advance is required, and it is becoming quite customary to discard the spark lever on cars where this system is used and run on a fixed spark. Improperly proportioned charges burn, of course, slowly, but in perfectly proportioned charges the flame travels extremely rapidly.

There are no single pole spark plugs on the market at the present time, so far as we are aware, but you might be able to get them from the Cadillac Motor Car Company, of Detroit, as this type of plug was used in the single cylinder Cadillac car which was marketed for a number of years. The single pole spark plug differs from the ordinary spark plug only in that the inner end of the central terminal, instead of being bent to come close to the shell, is made longer and bent so as to come close to the end of the corresponding terminal of the other plug.—ED.]

# Calculation of Stresses in Differential Gears.

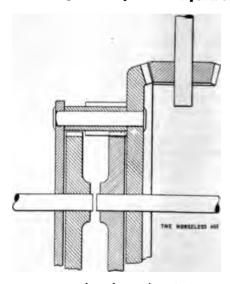

Editor Horseless Age:

As a subscriber to your paper I would like to ask a question that recently came up, and which is puzzling me. It concerns a Franklin Model D 1909 car. The motor of this car develops 28 horse power at 1,500 r. p. m. The transmission reduction is 3½ to 1, and the rear axle reduction 3¾ to 1. I want some method of finding the maximum fibre stress per square inch in the differential spur pinion. The accompanying sketch shows the arrangement of the differential. If I have not given all the necessary data, you may assume the quantities that are lacking, as it is the method of calculation that I desire particularly.

W. H. LEAVENWORTH.

[It may at once be stated that there is no method for precisely calculating the stresses in toothed gearing, but it is possible to make an approximation, and an attempt at this for the case in question will be made in the following:

If the engine develops 28 horse power at

1,500 r. p. m. then the engine shaft torque is

 $_{1500} \times _{2} \times _{3.1416} = 98.06$  pounds-feet.

The torque on the two rear axle shafts when the low gear is in mesh (neglecting losses in transmission) is then

98.06  $\times$  3½  $\times$  3½ = 1,224.5 pounds-feet. Only one-half of this torque comes on each of the rear axle shafts and on each of the spur gears secured thereto; that is, 612.25 pounds-feet. From this we can easily figure the pitch line pressure, if we know

the number of teeth in the rear axle spur gears and their diametral pitch, from which the pitch diameter can be calculated. Let us assume that the pitch diameter is 12 inches, which would make the radius onehalf foot. The pitch line pressure on the rear axle spur gears would then be

$$\frac{612.25}{1}$$
 = 1,225.5 pounds.

Usually there are three sets of pinions in a differential gear, and assuming this to be the number in the case under consideration, then the tooth pressure at each pinion is 1,224.5 + 3 = 408 pounds.

In spur gearing all of the pressure never comes upon one tooth, as another pair of teeth always comes into contact before one pair passes out of contact. According to Unwin the maximum pressure on each tooth is equal to from one-half the pitch line pressure to the full pitch line pressure, depending upon the least number of teeth. The pinions of a spur differential always have a very small number of teeth, and it will not be far from the truth to assume that the tooth pressure is equal to the pitch line pressure. (For average cases Unwin recommends to use two-thirds the pitch line pressure for the tooth pressure.)

Having thus determined the pressure on each tooth, the next thing is to find the stress which this pressure will cause in the material of the tooth. It is customary to regard a tooth as a cantilever, with the load applied at the end. Let L represent the load, h the height of the tooth, w the width of the tooth, and t the thickness of the tooth at the base. Then, according to the well known formula for cantilever beams, the maximum stress

$$S = \frac{Lht}{2I}$$

where I is the moment of inertia of the section under stress.

$$I = \frac{w t^3}{12}$$

Substituting this value of I in the above equation for the stress we obtain

$$S = \frac{Lht}{2wt^3} = \frac{6Lh}{wt^2}$$

The tooth pressure is, of course, the same on the pinion tooth and the gear tooth, but usually the pinion tooth is the weaker of the two, because with the small number of teeth in the pinion the teeth are usually undercut, and the bases of the pinion teeth are smaller than the bases of the gear teeth. In this particular case, however, the pinion teeth are strengthened by the fact that they are of greater width than the gear teeth, and the gear teeth are therefore probably the weakest. In substituting in the above equation for t it is therefore advisable to take the thickness of the gear tooth at the base.

You do not give the dimensions of the pinions and gears in the differential, and it is therefore impossible for us to figure the actual stress in these parts. We will illustrate the method, however, by assuming the dimensions. Suppose that the pinions have twelve teeth of 8 pitch, and that the face of the gears is five-eighth inch. In that case

$$h = \frac{1}{4}''$$
 $w = \frac{8}{5}''$ 
 $t = 0.2'' \text{ (approx.)}$ 
 $L = 408 \text{ pounds.}$ 

Consequently  $S = \frac{6 \times 408 \times \frac{1}{5}}{\frac{5}{5} \times 0.2 \times 0.2} = 24,480 \text{ lbs. per sq. in.}$ 

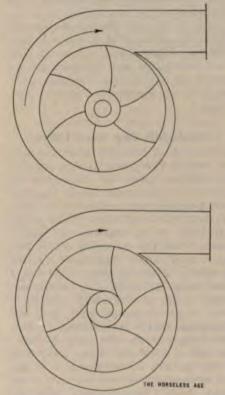

# Centrifugal Pump Designs.

Editor Horseless Age:

Would like to ask which of the two designs enclosed is the more efficient and to what extent. Does the direction of the curve of the blades affect the speed of rotation, and how much?

J. J. JENNINGS.

[Both of the designs seem to be quite practical, but we consider the upper one

SUGGESTED CENTRIFUGAL PUMP DESIGN.

the best, as the blades are slightly curved backward at the outer ends. As the water passes from the space between the blades into the diffuser its velocity parallel to the circumference of the wheel is reduced, and the backward curve of the blades facilitates this change in velocity and reduces the friction. It is quite impossible to give any figures for the difference in efficiency of the two designs.

The speed of rotation depends only on the speed of the driving motor and on the gear ratio. The curve of the blades would, however, slightly affect the rate of delivery.—Ep.]

### Rear Cylinders Sooting.

Editor Horseless Age:

I am having trouble with a Winton Model K. The two cylinders next to the dash will persist in sooting up, while the two front ones will remain perfectly clean. The compression seems good and the explosions are of about the same power. I don't think it is due to oil. We use Anti-Carbon and have cut down the oil to less than for the two front cylinders. The rings must be O. K., and I don't believe the oil is working past them.

I note that if a little increase is made in gasoline at the needle valve, the plugs in those cylinders seem to soot more and the front cylinders still show clean spark plugs. For that reason I thought the inlet valves might have something to do with it. As you know, this car has an air governing system. It might be that the air leaks out faster under one valve than another and one cylinder takes a larger charge, but I don't notice much difference in the explosions. I note, however, that one rear cylinder misses at times or has weak explosions.

I took the brass cap off of the dashpot over the inlet valve of this cylinder, and there were times that it chattered or jumped up and down a few times when first seating against compression. This, of course, would let out some of the charge and weaken the explosion or prevent it entirely. I expect to take out all the valves and regrind them if necessary and clean them up, and perhaps tighten up all the inlet springs a little and measure the tension on them if necessary I thought I would also put a gauge like the compressometer on one cylinder at a time and run the engine at a fixed speed, and take a comparative compression running. I rather think the rings are some of the cause.

C. E. F.

[The sooting must be due either to too much oil or too much gasoline, or both. It is not likely that the air governing system has anything to do with the trouble, as any defect in it would only affect the quantity of the charge admitted to the different cylinders and not the quality. If the trouble is due to air leaks, these leaks must be in the forward cylinders. They might require such an adjustment of the carburetor, in order to get a combustible charge into the front cylinders, that too rich a charge would be fed to the rear cylinders You can test this by observing the exhaust. If it contains black smoke (blue smoke is oil smoke), there is too much gasoline in the charge, and there should be a difference observable in the darkness of the exhaust from the front and rear cylinders respectively.

Too rich a mixture in the rear cylinders might cause the sooting, but in the majority of cases sooting is due to oil. You might get a good idea as to the actual cause by running the engine with the muffler off and closely observing the exhausts. If the trouble persists it may be advisable to provide external spark gaps in the circuits of the two rear cylinders, which, as you are probably aware, prevents failure of the ignition due to sotting. The soot would then not be objectionable until the coating became so heavy that it caused preignition.

—Fn.]

# Dry Cell Tests.

Editor Horseless Age:

On page 218 of No. 8, Vol. 24, you publish an inquiry, your reply, and a diagram of connections covering test of dry cells. The writer is rather at a loss to understand or rather reconcile your diagram to the statement in the article. The proposition mentions that twenty cells were in use, connected in two sets of ten. Presumably these two sets were so connected as to use first one and then the other. The diagram, however, shows that all the cells were in use simultaneously. Being connected in multiple series, either side of the two pole switch would pick up the entire battery, and eleven cells are shown in each series.

M. H. MOFFETT.

[Our understanding was that all of the cells were used simultaneously, and our reply was based on this assumption. Our correspondent, M. B. Johnston, informs us that the diagram was wrong, in that only five cells should have been shown in each row, instead of eleven. He adds that in the tests twenty cells were used simultaneously, ten of one make and ten of another, in four series of five each.

We would point out in this connection that a better method of making a comparative test of dry cells would be to connect the cells of different makes in series. Generally six dry cells are used in series, and three of each make could be used, or if two rows of six were employed, three of each make could be placed in each row. The advantage of this arrangement would be that the same current would then always pass through both makes of cells, and when the cells of one make became exhausted this would be indicated by misfiring. A simple voltage test would then show the state of discharge of each cell.—ED.]

# Berkshire Motor Car Company Reorganized.

The Berkshire Motor Car Company, of Pittsfield, Mass., has been reorganized with the following officers: John McQuaide, president and treasurer; Dr. William J. Mercer, vice president, and the foregoing together with Michael L. Casey, John White, Dr. O. S. Roberts, Clement Coogan, Henry Ryan and Harry Belcher, directors. Mr. Belcher has been superintendent of the company's plant from the start, and will continue to act in the same capacity. The company turned out about thirty cars the past year, and it is now planned to increase the capacity by leasing additional floor space in the Whittlesey building,

# Results of Munsey Tour.

In the Munsey Tour, which came to an end at Washington, D. C., on Wednesday of last week, only one contesting car, the Elmore, driven by Frank Hardart, Jr., of Philadelphia, came through with a perfect score, and this car was awarded the sweepstakes prize. The winners in the different classes and their scores were as follows:

			Points
Class.	Price.	Winner.	Penalized.
ı—\$	850 and t	ınder, Ford	6.9
2—\$	851 to \$1,	250, Maxwell	37.0
3-\$	1,251 to \$	2,000, Crawford	51.2
4\$	2,001 to \$	3,000, Elmore	0.0
5-\$	3,001 to \$	4,000, Am. Simple:	x 0.9
6—\$	A.oot and	over. Renault	

The Croxton-Keeton Motor Company, of Massillon, Ohio, who had two cars in the contest, withdrew them at New York. They inform us that the 45 horse power German type arrived at New York with a perfect score, and the 30 horse power French type was penalized four and onehalf points for breaking an unessential bolt. Their vice president, Mr. Bernhart, was threatened with a very serious illness on account of the wet weather encountered. and on the arrival of H. A. Croxton, their president, conditions were such in their New York branch that they demanded the immediate use of these entries for demonstration purposes, consequently they were with-

#### Vanderbilt Cup Race Plans.

The A. A. A. last week granted a sanction for the Vanderbilt Cup race, which is to be held on October 30. The course this year will be considerably shorter than last year, measuring only 12.64 miles, of which 5.15 will be on the Motor Parkway and 7.49 miles on the highways of Nassau County. This year the entries will be limited to stock chassis. The course is briefly as follows: From the grand stand east 2 miles along the parkway to Massapequa Lodge, thence in a northerly direction 2 miles to the Massapequa road, along the Massapegua road to the outskirts of Hicksville Village; thence west along the country road to Westbury; thence south back to the parkway at Meadowbrook Lodge, and thence along the parkway back to the grand stand. Simultaneously with the Vanderbilt Cup race the Long Island Motor Sweepstakes will be held. The Vanderbilt Cup race is open for stock chassis of Classes 1 and 2, Class 1 comprising cars with 451-600 cubic inches piston displacement of a minimum weight of 2,400 pounds, and Class 2 cars of 301-450 cubic inches piston displacement of a minimum weight of 2,100 pounds. The entry fee for the Vanderbilt Cup race is \$500 per car. The circuit of 12.64 miles is to be covered twenty-two times, which makes the total distance to be run 278.08 miles. The Sweepstakes comprise an event for Class 3 for the Wheatley Hills Trophy. This class comprises cars of 231-300 cubic inches piston displacement, of a minimum weight of 1,800 pounds. The distance to be covered is

189.6 miles, and the entry fee is \$250. Also an event for Class 4 for the Massapequa Trophy. This class comprises cars of 161-230 cubic inches piston displacement, of a minimum weight of 1,500 pounds. The distance is 126.4 miles, and the entry fee is the same as for Class 3. Entries for all of the events close on October 25.

#### Preparations for Atlanta Show.

A fund is at present being raised in Atlanta, Ga., for entertaining the manufacturers, salesmen and others who will attend the automobile show there next month. It is stated that already over \$15,000 has been received by the executive committee. In order to take care of the large number of visitors which are expected at Atlanta during the show, a public comfort department has been established, with S. C. Dobbs as chairman, which will engage to find lodgings for visitors. Invitations to attend the show will be sent out to every dealer and garage man in the District of Columbia, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Texas, Alabama, Mississippi, Louisiana, Arkansas, Missouri, Kentucky and Tennessee. In addition, about 1.100 invitations will be extended to carriage dealers in the above States. Those to whom invitations have been issued will be admitted to the show free.

### Every Town Its Own Auto Factory!

The following is from the Findlay (Ohio) Jeffersonian, and is characteristic of a movement that pervades the Middle West. Similar articles have appeared in numerous other country papers recently:

"Findlay ought to have an automobile factory.

"In recent years the automobile industry has had a marvelous development, and the near future promises it further growth equally great. Despite its rapidly increasing number of automobile factories, the United States has a heavy import trade in motor cars. The demand is such that more factories are bound to spring up throughout the country, and Findlay should have one of these plants.

"Findlay has plenty of capital, which, it seems, could be employed profitably in this line. There are auto enthusiasts here who should take hold of the matter. It is a proposition deserving of their consideration.

"Not a great deal of capital would be required, and the market is waiting.

"The farmers are to be heavy purchasers of autos for some years to come, as they will be the people with money. With the prosperity that has come to them they will not be content to move slowly along the highways taking the dust of others when they are able 'to make the dust fly' themselves. So many farmers now have autos that it is the subject of special comment by Secretary of Agriculture Wilson.

"It is up to Findlay automobile people to launch the project, get a competent manager and go ahead."

# Commercial Applications.

### Taxicab Developments in Boston.

In connection with the article "The Taxicab Business in Boston and Vicinity," which appeared in our issue of August 25, we are informed that the Taxi-Motor Cab Company, of Boston, have a maintenance contract with the Shawmut Tire Company, of Boston, who keep two men at the taxicab garage day and night for the purpose of shifting and repairing tires. The company are changing over from the rear wheel taximeter drive to the front wheel drive, and in a short time all of the taximeters on their cabs will be driven from the front wheels. The company have placed orders for a considerable number of cars, and expect to have between 100 and 125 in service late this fall. They have lately taken a long term lease on the Cyclorama Building at 541 Tremont street, which affords storage space for 250 cars. They also have a number of Pope-Hartford touring cars in service, which are rented by the hour, day or week, and they expect to considerably extend this part of the business.

#### Chicago Taxicab Combine.

The Automobile Transportation Association was incorporated at Springfield, Ill., on October 1 by O. H. Fay, of the Owen H. Fay Livery Company; John B. Haartz, secretary of the Walden W. Shaw Company, and Arthur B. McCoid, counsel for the Chicago Auto Livery Company, all of Chicago. In the incorporation papers it is stated that the association is organized for the mutual benefit of its members, and is of the "not for profit" class of corporations. Besides the firms represented by the incorporators, the association comprises the City Motor Cab Company, which is represented by John Borden, and the Auto Taxicab Company, represented by Max Morris. The above are the five most important taxicab operating concerns in Chicago. The objects of the association are stated to be the regulation of taxicab schedules and the protection of the members against attacks by legislation and against ruinous competition. It is understood that the five concerns comprised in the association will adopt a standard taximeter and a standard schedule of charges.

### Commercial Notes.

The owner of the automobile line between Mt. Pleasant and Wheeling, W. Va., is reported to be planning to establish a similar line between Blaine and St. Clairsville, Ohio.

The Taxicab Company of Baltimore, Md., have secured a building at Howard and Franklin streets, which they will occupy October 15. They have recently ordered fifteen more taxicabs from the Autocar Company, which when delivered will give them thirty-one all told. They have stands at the Union Depot, the Camden station and all the hotels except the Renner.

The Seattle (Wash.) Taxicab Company suffered a loss during the past week of \$285 contained in seven change sacks, turned in by various drivers, which were stolen by the night dispatcher of the company.

The Pacific Car Company, of Tacoma, Wash., inaugurated a taxicab service on October I. Six Cartercars are used. Stands have been secured at the leading hotels, the main office being at 717 South C street. C. L. Ross is manager of the company.

The Autocar Company, of Ardmore, Pa., on September 30 delivered five new motor mail wagons to the post office in Philadelphia. They are first to be used tentatively, and if found satisfactory the mail in Philadelphia will in future be handled exclusively by motor cars.

The Frank Bird Transfer Company, Indianapolis, Ind., have purchased three Coppock taxicabs and put them into service. They have been doing a horse livery business for thirty years, and if their present enterprise proves successful they expect to add a motor truck livery service.

The Stewart Cab and Auto Company has introduced a taxicab service in Baltimore during the past month, using six Alco cabs. They operate a stand at the Renner Hotel. Mr. Stewart has been in the livery business in Baltimore for fifteen years, and says that if the taxicab business pays he will give up the horse livery business entirely.

J. W. Bearup has been operating a motor freight service between Manhattan and Tonopah, Nev., for some time. Mr. Bearup uses a Lambert truck, and makes a specialty of carrying perishable goods from the cold storage establishments in Tonopah to Manhattan, for which trip he requires four hours. At present one trip is being made every other day.

The Suburban Motor Transit Company, a recently incorporated concern of Perth Amboy, N. J., plan to operate a number of thirty passenger, 40 horse power motor omnibuses between Elizabeth and the Amboys. The buses will pass through Elizabeth, Linden, Rahway, Roosevelt, Chrome, Port Reading, Woodbridge and the Amboys. The company are incorporated under New Jersey laws, and plan to run ten buses at once on a half hourly schedule.

The Fairfield Dairy Company, Montclair, N. J., have recently placed in service a 1 ton Baker electric truck, equipped with forty-two cells of 9 M. V. Exide battery, and a 3½ horse power series motor, having an overload capacity of 300 per cent. The truck has a 92 inch wheel base standard tread and 34 inch wheels, with 3½ inch rubber tires. The front axle is an I section drop forging, and the rear axle is solid forging. Timken roller bearings are used in the road wheels, and imported ball bearings in the motor and countershaft.

# The New French Automobile Taxes.

The French Minister of Finance Cochery has submitted to the Budget Committee of the Chamber of Deputies a plan of taxation of automobiles, according to which not only is the tax on domestic automobiles to be considerably increased, but foreign motorists who tour in France will also be subjected to a tax if they stay in the country longer than ten days per year. As in the case of the present French automobile tax law, the new tax consists of two parts, as it were, a seat tax and a horse power tax. For domestic cars the seat tax, according to Mr. Cochery's plan, is to be as follows:

	Passen- gers.	More Than Two Passengers.
Vehicles of 10 Horse Power,	Francs	Francs.
Paris Cities of more than 40,000 inha		90
itants	40	75
Cities of 20,000-40,000 inhabitan	its 30	60
Cities of 10,000-20,000 inhabitan		50
itants	20	40
	Two	More

Vahislas Char ve Hann Banna	Passen- Than gers. Passe	ngers.
Vehicles Over 10 Horse Power.	Francs, Fr	ancs.
Paris	50	90
Other cities	40	-

The horse power tax is set down as

								1	rancs.
1-10	h.	p.,	per	horse	power.			-	5
11-20	h.	p.,	per	horse	power	addition	al		10
21-40	h.	p.,	per	horse	power	addition	al		15
41-60	h.	p.,	per	horse	power	addition	1a1		20
61-80	h.	D.,	per	horse	power	addition	nal.		25
80 h.	p.,	pe	r ho	rsc po	wer ad	ditional.			

At present French motorists pay the same seat tax, and in addition 5 francs per horse power, so the tax on cars up to 10 horse power would not be changed.

In applying the tax to foreigners who may be using their cars in France the seat tax would be 50 francs for a two passenger car and 90 francs for a four passenger car. This is for a period of 360 days, and touring motorists may get tax permits for one or more periods of thirty days.

Motor boats are to be subjected to the same tax as automobiles. The tax on taxicabs and livery cars is to be 80 francs for two passenger vehicles, 100 francs for three passenger vehicles, 125 francs for four passenger vehicles, 150 francs for five passenger vehicles, and 175 francs for six to eight passenger vehicles.

The Budget Committee has reduced the horse power tax as follows:

							Francs
1-12	h.	Pos	per	horse	power.		 . 5
13-24	h.	p.,	per	horse	power	additional.	 . 7
25-36	h.	p.,	per	horse	power	additional.	
37-60	h.	p.,	per	horse	power	additional.	 . 12
61 h.	p.,	per	r ho	rse po	wer add	litional	 . 15

On a four passenger, 24 horse power car the tax under the present law is  $5 \times 24 + 90 =$  210 francs.

Under the Cochery proposed law it would be  $90 + (5 \times 10) + (10 \times 10) + (4 \times 15) = 300$  francs.

Under the modified Cochery law the tax would be  $90 + (5 \times 12) + (7 \times 12) = 234$  francs.

#### Recent Decisions.

INTERPRETATION OF IOWA LAW.

The Iowa statute limiting speed, and requiring an automobile to signal in passing horses, was held not to relieve the driver of a car from exercising reasonable caution in passing a horse in the absence of a signal. To operate an automobile at a greater rate of speed in the city than is allowed by statute was held to be negligence. Whether a signal from an automobile horn is necessary in the exercise of ordinary care was held to be determined by the circumstances of each case. The question of negligence in passing a team in a city within a few feet of it without warning was held to be one for the jury. Where, after passing and frightening a team, the driver of an auto stopped some 30 feet ahead, thereby frightening it more and causing it to run away, it was held proper to leave it to the jury as to whether this stopping of the car was negligence. The driver of a vehicle was held not required to look out backward, and is entitled to rely on the use of ordinary care by those approaching from the rear. Unlawful speed of an automobile in passing a horse in the street, causing it to take fright and run away, was held not of itself to warrant a recovery.—Delfs vs. Dunshee. Iowa, 122 N. W., 236.

### GARAGE OWNER'S LIABILITY.

A garage contracted with the owner of an automobile not to allow it to be taken out at night without a written order. The chauffeur, at a rush hour, got by the watchman at the door, in the machine, and the machine was found on Long Island wrecked. It was held that a verdict for the plaintiff was sustained by the evidence, and the question of defendant's negligence was one for the jury.—Wilson vs. Wyckoff, Church & Partridge, 117 N. Y. Supp., 783. OWNER RESPONSIBLE WHEN LOANING MACHINE.

A chauffeur was allowed to use the machine for taking a pleasure trip with some boon companions. It was held that the owner of the automobile should be responsible for injuries caused by it through the negligence of anyone he permits to use it in the public streets.—Ingraham vs. Stockamore, 118 N. Y. Supp., 399.

# Enforcing Indianapolis Drivers' Registration Ordinance.

Orders have been issued to the police by the board of public safety at Indianapolis to arrest all automobile drivers who have not secured registration badges. During the last week upwards of twenty arrests have been made. The ordinance requires that every person driving a car, whether the owner of one or not, must register with the board and city controller: The registration fee, which need not be renewed, is \$1. For a third conviction for violating any automobile ordinances or laws, the registration is automatically revoked, and driving an automobile after the license is thus revoked will subject the driver to a fine of not less than \$50 to which must be added not less than fifteen days' imprisonment. About 2,000 drivers of the estimated 5,000 drivers in Indianapolis have registered.

#### Auto Appropriation Cut.

The city council of Indianapolis has declined to appropriate \$2,500 for the purchase of a new automobile patrol wagon for the police department, as requested by Mayor Bookwalter. The department has two automobile patrol wagons, and the council believed this to be sufficient. It also reduced a requested appropriation for the maintenance of the police machines during next year from \$3,600 to \$500.

#### Buffalo Garage Ordinance.

The ordinance committee of the Buffalo, N. Y., board of aldermen gave a publica hearing on October 3 on an ordinance introduced by Alderman Eberle relating to the establishment of garages in residence districts. The bill provides that it shall be unlawful to establish a public garage in any block in which two-thirds of the buildings are devoted to residence purposes without the written consent of the owners of the lands. The consent of the common council is also required. If the garage is so conducted as to be a public nuisance or injurious to health the permit may be revoked. The ordinance does not affect garages constructed and in use prior to October 1, 1909.

## Legal Notes.

Mayor Wm. S. Jordan, of Jacksonville, Fla., has vetoed the automobile tax ordinance recently passed by the council, after giving hearings to members of the council and private citizens who chose to call on him in the matter. The mayor considered the tax excessive.

A. C. Runkel's attempt to defeat the Milwaukee, Wis., council order prohibiting cars from standing at the curb on Grand avenue or Wisconsin street has come to naught. The prosecution changed the charged offense to disorderly conduct and Mr. Runkel was fined \$1 and costs.

Recorder McGovern, of Hoboken, N. J., last week fined the New York Taxicab Company \$10 for soliciting fares in Hoboken. Seventeen of the company's drivers were arrested in Hoboken early in the week for soliciting fares without a license in Hoboken. It is said to be likely that the case will be carried to a higher court.

The Wisconsin legislative committee on goods roads started on October 3 on a long tour of neighboring States to gain

ideas for framing bills to be presented to the special session of the Legislature in January. Michigan will be the first State visited. The committee attended the National Good Roads Convention at Cleveland in a body and obtained much valuable information to work on.

# Plans for Bay State Endurance Run.

The Bay State Automobile Association. of Boston, Mass., plans to hold another reliability run this fall. It is planned to have a two days' contest over a distance 450 miles in length. The route has not vet been definitely selected, but it has been suggested that two round trips should be made. both of them beginning and ending at Boston. The first route is from Boston to Quincy, Holbrook, Brockton, Bridgewater, Middleboro, New Bedford, Fall River, Taunton, Providence, Pawtucket, Woonsocket, Worcester, Pittsburg and back to Boston: and the second route leads from Boston through Lowell, Nashua, Manchester, Concord, Dover, Portsmouth, Newburyport, Haverhill, Lawrence, Salem, Lynn and back to Boston. A technical examination of the cars will follow the road trial, and will have an important influence on the awards.

### Another Race Planned on Indianapolis Speedway—Aviation Meet Off.

A race meet for November 1 has been announced by the Indianapolis Motor Speedway Company, to be held in Indianapolis, on the new brick course which is now being constructed. It is expected the work of paving the course will be completed within the next ten days or two weeks The speedway management has abandoned plans for an aviation meet. which was to have been held at the speedway October 14-15-16. This decision was reached after it was found Glenn H. Curtiss demanded \$12,000 for himself and a second driver, and flights were not guaranteed.

# Contract for Ohio Number Plates Let.

A contract has been awarded by the Ohio State Automobile Department for 30,000 sets of 1910 number plates to the Enterprise Enameling Company, of Bellaire, Ohio, at a saving of \$3,600 over the price paid in 1909. The plates will be of sheet metal covered with enamel. The background will be mahogany color and the figures and letters white.

In a letter of instruction sent out by State Registrar of Automobiles Fred H. Caley owners are informed that application blanks will be distributed in thirty days. Numbers for next year will be given out in the order of receipt of application. Number plates will be shipped out to arrive at their destination the last day of the year.

# GARAGE **ITEMS**

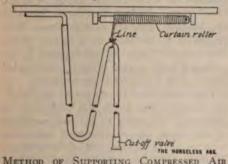

New Dayton, Ohio, Garage.

The Peckham Motor Car Company, of Dayton, Ohio, are building an up to date garage and salesroom, which when finished will be the home of the Peerless and Buick cars. It is expected that the building can be occupied by November 15 at the latest. The main building will be 70x100 feet, with three stories and basement. It will have a wing of two stories and basement. The basement will be entirely surrounded by light shafts, making it as light as the other floors. The basement of the main building will be used for storage, washing, etc. The ground floor of the main building will be used for transient storage; the next floor will be given over entirely to electrics, and will be so equipped that every repair on an electric can be made. The top floor of the main building will contain the repair and machine shop. The wing will be given over to showrooms, the basement being finished the same as the ground floor, except that the office will take up part of the room on the ground floor. The top floor of the wing will be devoted to bathrooms and supplies. There will be shower and tub baths provided for both ladies and gentlemen, and large dressing rooms for each, where the tired tourists can bathe and refresh themselves. The building is of reinforced concrete, absolutely fireproof.

A Garage Convenience.

Comparatively few large garages nowadays are without a power air pump for the purpose of supplying air for the inflation of tires. It is a rather vexing problem what disposition to make of the hose when not in use. In most cases a hook is provided on which it may be coiled when not in use. As often as not it is left on the floor after use, to be run over by machines and to be in-

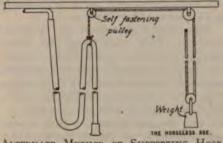

jured more or less by the action of oil or gasoline which is almost sure to drip on it. A rather simple but ingenious solution of the problem has been evolved at the Palace Garage in Hartford, Conn. The main air tube is led along the ceiling and the rubber tube connected at this point. An automatic curtain roller is secured in a frame and fastened to the ceiling near at hand. A light

line is wound on this roller and the end se-

HOSE.

cured to the rubber hose about a third of the way from the end. When not in use the tube is suspended out of the way. When wanted for use it is only necessary to take the end of the hose where it is wanted. Of course, a valve is provided near the "business end." When the person using the hose is through with it, all that is necessary is to give a slight jerk and let

ALTERNATE METHOD OF SUPPORTING HOSE.

go, when the hose will be removed out of

This arrangement might be simplified by using a couple of pulleys and a weight in place of the curtain roller. The one on the ceiling next the hose might be one of the self-fastening kind sometimes used on large window curtains.

Seattle Dealers to Organize.

Automobile dealers of Seattle, Wash., recently held a metting with the object of forming a trade organization, to be known as the Seattle Automobile Association. A temporary organization was perfected, Robert Guggenheim being elected temporary president and Clarence H. Jones temporary secretary. A committee on permanent organization was named, with James H. De Veuve as chairman, and another meeting for permanent organization is to be held at the Rainier Club on October 8. Among the objects of the organization are to stimulate interest in automobiling, to promote the construction of improved highways and to hold automobile shows, races and endurance contests.

# Columbus, Ohio, Club Planning Show.

At a meeting of the Columbus (Ohio) A. C. arrangements were made for a motor show, to be held at the Columbus Auditorium, some time in January or February, midway between the dates of the Cincinnati and Cleveland shows. A committee consisting of Perin B. Monypeny, O. H. Perry, Fred H. Caley, Herman Hoster and N. O. Aeby was named to arrange the details. The proposed two days' race meet in October was abandoned because of the fact that racing has been overdone in that section. It was decided to postpone "Old People's Day" until next year because of the lateness of the season, The club pledged itself to support legislation for the betterment of automobiling, and particularly the enactment of a State highway law having as its chief provision perpetual maintenance by the contractor.

# Annual Fuel and Oil Consumption in Automobiles-

The following figures may possess a certain interest to those who have a fondness for statistics. It is estimated that there are about 200,000 motor cars in operation in this country. Assuming that each of these cars is run 3,500 miles per annum, and that the average distance covered by the expenditure of a gallon of gasoline is 14 miles, a total of 50,000,000 gallons of fuel is consumed by these cars annually. At 15 cents per gallon this represents an expenditure for fuel of \$7,500,-

Assuming that the volume of lubricating oil used is 5 per cent, of the volume of gasoline consumed, 2,500,000 gallons of oil should be required for the lubrication of these cars, which, at 60 cents per gallon, would cost \$1,500,000 per annum. A cylindrical gasoline tank 100 feet in diameter and 850 feet in length would be required to hold the year's fuel supply, and an oil tank of the same diameter, but 42 feet long, to contain the lubricating oil supply.

### Space Allotments for Grand Central Palace Show.

When the applications for space for the coming Grand Central Palace Show, in New York, closed on September 29, it is stated that 110,000 square feet of floor space had been applied for, 5,000 square feet more than last year. Only 72,000 square feet is available, and the applications for space will, therefore, have to be cut considerably. The drawing for space will be held at the A. M. C. M. A. headquarters, 505 Fifth avenue, New York, on October 8. First the members of the A. M. C. M. A. will select their spaces, then the show committee will allot space to motor car makers who are not members of the A. M. C. M. A., after which accessory makers not members of the M. & A. M. will have spaces allotted to them.

Paige-Detroit Company Organized. The Paige-Detroit Motor Car Company

has been organized in Detroit, Mich., with a capital stock of \$100,000, and the following officers: Frederick O. Paige, president and general manager; Willis Buhl, vice president; Wm. B. Cady, secretary, and Gilbert W. Lee, treasurer. The company have taken a lease of the old Stearns laboratory building on Twenty-first street, and have placed orders for the necessary machinery. The first product of the company will consist of a three cylinder, two cycle runabout, to sell at \$800, and it is expected to begin the delivery of cars by December 1.

# Business Troubles.

An involuntary petition in bankruptcy has been filed against the International Automobile Company, of Chicago, by the Chicago Record-Herald Company, the Automobile Trade Directory and F. S. Howard. The liabilities amount to \$1,500.

# MINOR MENTION

The Waterloo Auto Parts Company is being organized in Waterloo, Ind.

Sears, Roebuck & Co., Chicago, Ill., are employing about fifty men in assembling their motor buggy.

The Seattle Automobile School has been established at 210 Broadway, Seattle, Wash., with day and night classes.

The Bissell Motor Company, of Toledo, Ohio, has filed notice of an increase in its capital stock from \$10,000 to \$200,000.

In the Long Island Stock Chassis Derby last week the winners in Classes I to 4 were equipped with Michelin tires, and the winner in Class 5 was equipped with Ajax tires.

D. W. Lawrence & Co., manufacturers of air pumps in Sterling, Ill., will shortly move to a building on West Third street, in that city, where certain improvements are now being made.

It is announced from Greensburg, Ind., that Harry Hamilton, of the Hamilton Garage Company, of that city, will open an automobile factory there, with the aid of local capitalists. It is planned to turn out a \$1,700 car.

W. R. Roberts, of El Reno, Okla, manager of the Pioneer Car Company of that city, plans to move the plant of the company to Wichita, Kan. The company manufacture both two passenger and four passenger cars

The Selden Motor Vehicle Company, Rochester, N. Y., have taken out a building permit for a two story brick factory building, 61x297½ feet, on Probert street, adjoining the New York Central tracks, at an estimated cost of \$43,000.

During the 10 mile race held at Mil-waukee, Wis., under the auspices of the Milwaukee A. A. on October 2, a Petrel car crashed into the fence and turned over, and both occupants were thrown out. Both were badly injured, but will recover.

The Ruggles Motor Company, which was recently organized in Springfield, Mass., to manufacture an improved two cycle motor, has leased the plant of the Massachusetts Ball and Machine Company at Gilmore and Cross streets, and will begin operations at an early date.

The new models of the F. B. Stearns Company, of Cleveland. Ohio, are all equipped with demountable rims, and an extra rim is furnished free of charge. In

case two sizes of tires are specified, as, for instance, 36x4 inch front and 36x4½ inch rear, two extra rims are furnished, one of each size.

The Timken Detroit Axle Company, Detroit, Mich., have purchased fifteen lots, covering about 1¾ acres, on the north side of Hickory avenue and the east side of Park avenue, for \$10,000. It is understood that the company will build an extension to its plant on these premises.

The Schacht Manufacturing Company, Cincinnati, Ohio, have bought the buildings at 2727-2735 Spring Grove avenue. The property comprises two well equipped buildings, 100x500 feet, both four stories high. The company are preparing to double their output of stock cars for 1910.

Thirty thousand square feet of floor space will be added to the plant of the Krox Automobile Company, Springfield, Mass. Another new building, giving 30,000 square feet more, will be erected in the spring, and a new power house is now being constructed to furnish 400 horse power in addition to the 250 horse power at present used.

The St. Louis Automobile Accessory Dealers held a meeting at the Blue Glass Hotel September 19. Among the topics discussed was that of credit, and Secretary Benoist explained the object of the credit bureau over which he presides. The Maxwell-Briscoe Motor Vehicle Company, of which M. W. Doyle is manager, was admitted to membership.

The Republic Motor Car Company is being organized at Hamilton, Ohio. At a stockholders' meeting, held on September 29, George H. Helvey was elected president, Chas. U. Carpenter vice president, Clarence Helvey secretary, Fred B. Rentschler treasurer, and G. F. Helvey factory manager and engineer. The company will manufacture automobiles.

A stock company is being formed in Carthage, Mo., for the manufacture of the McKiearnan automobile. P. E. Hannam will act as president of the company, which will locate in a factory building on Main street belonging to him. A committee headed by Mr. Hannam has been appointed to secure subscriptions for \$50,000 worth of stock from local investors.

Lakeside Forge and Wrench Company have acquired the plant of the Springfield Drop Forge Company, of Springfield, Mass., and began operations with a full force of men on September 27. Eugene Childs, who was formerly connected with the Trimont Manufacturing Company, of Roxbury, Mass., has been elected president and general manager of the Lakeside Company.

John Bohnet & Co., of Lansing, Mich., manufacturers of auto tops and other automobile accessories, have leased the upper two floors of the main building of the Clark & Co. carriage plant, which they will occupy November 1. The firm is reported to have just closed a contract to paint and trim 4,000 automobile bodies for an Indiana manufacturer, and also paints and

trims the bodies of the cars built in the Clark factory.

The K-W Ignition Company, of Cleveland, Ohio, inform us that they have again doubled their floor space and will manufacture their magnetos and coils on a much larger scale next season.

The assessment lists of Outagamie County, Wisconsin, show fifty-seven automobiles and no bicycles. There are said to be a great many bicycles in use, but the assessors apparently consider them not worth bothering about for purposes of taxation.

The Prest-O-Lite Company, of Indianapolis, Ind., will shortly establish a retail sales office in Minneapolis, as well as a plant for recharging their gas tanks. James A. Allison, a member of the firm, was in Minneapolis recently to secure suitable quarters.

The Pennsylvania State authorities have granted a charter to the Ewing Automobile Company, who recently removed from Geneva, Ohio, to Easton, Pa. The capital stock mentioned in the incorporation papers is \$10,000. The company will shortly start work on a plant on a 10 acre site along the Easton & Northern Railroad.

The Diamond Rubber Company have opened a branch at 46 Auburn avenue, Atlanta, Ga. The branch is temporarily in charge of W. F. Vodes, auditor of the company, but later on W. F. West, of Mobile, Ala., will become manager. It is stated that the company plan to cover the entire Southern territory from this branch.

The Studebaker Automobile Company is publishing the "log book" of Walter Hale, who toured Europe in a Studebaker-Garford car last summer. It contains an illustrated description of the trip, giving road maps, distances, taxes, passport fees and other information. Copies of the booklet will be furnished by the Studebaker Company free of charge on request.

The Leach Automobile Company, a New Jersey corporation with a capital stock of \$500,000, of which Charles Leach, of Lima, Ohio, is the principal, are negotiating with the business interests of Columbus, Ohio, regarding the location of a factory there. The company plan to manufacture a car equipped with a two cylinder, air cooled motor, and a patented transmission.

The twenty-four hour race on the Brighton Beach track, which was postponed on September 24, owing to the bad condition of the track, due to continued rains, has been set for October 15 and 16. The Bosch Magneto Company offer a prize of \$100 to the winning car, provided it is fitted with a Bosch magneto, and an additional \$50 if the record of 1,091 miles established by Robertson is broken in the race.

#### Club Notes.

The New Orleans A. C. is organizing what is to be known as the Louisiana Good Roads Convention, to be held at New Orleans November 20 and 21. In connection with the convention there will be a series of automobile races, including a six hour

event for different classes of cars, according to cylinder capacity.

# Simplification by Combination of Parts and Multiplication of Functions.

By ALBERT L. CLOUGH.

In one sense of the word the motor car of today is essentially the same as that of ten years ago. There are the motor, the change speed gear, the transmission and the running and steering gears. The motor still requires to be cooled, lubricated and ignited, and it and the rest of the mechanism require to be controlled and oiled.

While these elements and their functions remain in a broad way identical, it is interesting to observe several directions in which simplification has progressed, and is progressing, despite the fact that the adoption of multi-cylinder motors and a greater number of speed changes have resulted in that kind of complication which is brought about by the multiplication of similar parts.

This simplification, which is such a desideratum from the standpoint of the user, as well as that of the manufacturer, has mainly been of the two following types:

(1) That in which several previously separate elements, either similar or dissimilar, are consolidated into a single structure, involving a lessening of weight, improved strength and neatness of appearance, the elimination of fastening devices and better facility in assembling, and

(2) That in which a single element, intended primarily to perform a specific function, is made to perform or assist in performing other functions, by attachments thereto or by means of a special conformation of the part.

It may be rather interesting to note some examples illustrative of these lines of simplification, and the following are a few which come under the first head.

BLOCK CYLINDERS.

Casting cylinders en bloc is an obvious example of the combination of two, three or four similar parts in one structure, resulting in a simplification of the machinery and assembling processes at the expense of some added complication in the pattern making and founding. Reduction of weight, higher rigidity, a reduction in the number of fastening devices, and cleanness in design, are secured thereby.

The incorporation of the intake manifold in the "bloc" is another correlative example, resulting in reduced external complication, a higher degree of engine accessibility, greater facility in cleaning the motor, and reduced fastening devices with their liability of leakage.

Similarly the provision of passages within the bloc, which take the place of water piping, tends toward simplicity and offers similar advantages, including convenience in assembling and dismounting the motor, external simplification and the freedom from leaks which comes from the reduction of joints.

COMBINED CYLINDER AND CRANK CASE.

In this same connection may be mentioned the consolidation of the cylinders and the upper half of the crank case in a single casting, which is beginning to be practiced in en bloc construction. A whole set of fastenings is thus eliminated, and the movement is in the direction of simplification. Related to this practice is that of making engine and auxiliary gear and shaft housings integral with the crank case casting, and of combining therewith magneto, pump and oiler brackets or beds.

CRANK CASE AND GEAR CASE UNITS.

A combination between the crank case and the case or bed forming the housing for the gear set and clutch is another example of consolidation, which simplifies the assembling and aligning processes, saves weight, increases rigidity, and conduces to a clean design. All unit power plant designs exemplify this practice of combination of the parts more or less, but in some the consolidation is less intimate than in others, merely consisting in bolting together the two otherwise separate parts. In most of these unit power plants separate control pedal brackets are dispensed with, the pedals operating upon brackets integral with the gear case, which is conveniently located so as to permit this.

CORED OIL CHANNELS.

Another manner in which crank case design can be made to embody another set of elements is by the casting within its walls of the oil distributing passages and the support for the pump which moves the lubricant, together with its driving mechanism. Simplification results from the elimination of external piping and fittings, and the obviation of a pump mounted as a separate

In a number of designs the clutch housing and the gear box are consolidated, leading to a reduction of the number of parts to be assembled upon the chassis, and probably some weight reduction.

REAR AXLE GEAR BOX.

The familiar rear axle mounted gear box is an example of the combination in what

is, from the standpoint of the assembler and the user, a simplified form of the rear axle housing, the change speed gear and the differential housings. In some planetary designs the clutches have also been housed in the same unit. Combination of parts may be more or less intimate in accordance with the details of the design, but the simplification is mainly noticeable in assembling, although the appearance of simplification is very marked. Speaking of gears, the cutting of a pinion integral with its shaft is a worthy example of consolidation in the direction of simplification. Keys and keyways are eliminated, and greater reliability is secured. The cutting of cams integral with their shaft is closely analogous to this.

#### ONE PART AXLES.

The running gear also furnishes examples of the practice of making two or more things "in one," in the interest of simplification, and even more of reliability. A single forging now comprises the front axle, the spring seats and the steering forks. Formerly these latter parts were pinned and brazed to the axle tube. Rear axle housing, driving gear case and rear spring seats are now formed of a single steel stamping, the pinning and brazing of tubes to their fittings, and the bolted fastening to the central housing portion, as formerly practiced, being eliminated.

Examples are even to be found about the frame. Spring horns, which were formerly riveted to the side member ends, are now formed integral therewith, and the front spring horns are even fitted with the head-light bracket sockets.

The radiator, which was formerly a set of finned pipes, drawing from an entirely separate tank located under the hood, now combines, as a single structure, the heat dissipating surfaces and the tank holding the reserve water supply.

Even the ignition wiring shows the tendency toward consolidation and external simplification. For example, the solid bar of insulating material into which are molded all the conductors which pass along the engine. By the combination of the turning and distributing elements in a single device, the distributor, all but one of the ignition coils otherwise needed are banished from the dash.

Everywhere is evidenced the endeavor of the automobile engineer to consolidate, to make the whole a combination of as few distinct structures as possible. The development of the low priced car has been mainly achieved by attention to this principle, reduction in weight, lessened cost of machining, and an enormous decrease in the cost of assembling having been attained in this manner. Combination of parts gives the user a car which is light, which has few fastening devices to work loose, which is very simple in appearance, readily kept clean, and which is decidedly better qualified to inspire confidence.

Plenty of examples of the use of a single element to perform more than one function are to be found, and it is the obvious aim of the designer to carry this principle as far as it can profitably be extended.

#### CONTINUOUS WEB ENGINE SUPPORTS.

We see the engine supports made in the shape of a continuous web, which forms a pan to protect the motor from road dirt. The separate sod pan under the motor is thus eliminated, and its weight and cost are saved. Instead of employing a separate oil reservoir, mounted upon the dash or under the hood, the lower portion of the crank case is so used, or one of the supporting arms of the motor is converted into an oil tank. Channels in the connecting rods and crank shaft serve as oil distributing leads, and separate ones are not required.

#### FAN FLYWHEELS.

The flywheel, in addition to its familiar extra functions as a clutch member and an index for ignition and valve setting, is cast with fanlike spokes, or has fan or blower blades attached to it, and takes the place of the radiator fan. eliminating it and its driving devices. The designer may go even further and fit the flywheel with permanent magnets, which, revolving in proximity to stationary coils. generate the magneto ignition current, thus obviating the necessity of a separate magneto, its driving shaft and gears, and the housings which protect them.

Moreover, the flywheel may be used as an oil pump to lift the lubricant from the wheel pit to a higher level, from which it is distributed through channels to the various bearing surfaces. The use of the connecting rod tips as oil distributors is a familiar example of a double function. Such applications of moving parts to perform the functions of the oil pump and distributor tend toward the elimination of the separate oil pump and its driving mechanism.

In the valve mechanism one push rod may be used to operate two valves, and a reduction of parts may thus be secured. The flexible cover plates of the water jackets may be made not only to serve their primary purpose of confining the circulating water, but also as safety devices guarding against the breakage of the cylinder casting, in case freezing occurs, and the flexible coupling driving the pump may also act as a safety device of the "weak link type," to prevent damage due to foreign substances in the circulating system.

#### TORQUE RESISTING SHAFT HOUSINGS.

The casing of the drive shaft is made at not only as a housing but as a torque

resisting member and as a distance rod, and thus a complicated system of rods, swivels and links is done away with, and their expense and weight are obviated.

Two independent brakes are made to operate side by side, or internally or externally upon the same rear wheel drums, and the same pedal which disengages the clutch is made to apply the service brake.

In the gear box one of the direct drive clutch members is the middle speed pinion, and the other member is formed by the internal teeth of the constantly meshed gear of the clutch shaft.

The distance rod is used as a functional part of the shock absorber in a well known runabout

Such examples illustrate very nicely the "boiling down" process which automobile design is subjected to in order that the number of essential parts may be decreased as nearly as possible to the "irreducible minimum." It is only when this is accomplished that a mechanism is producible which shall possess no superfluous weight, which shall be cheap to manufacture, cheap to maintain, and free from the evils which arise from complexity. Simplicity, coupled with good material, well placed as regards the stresses which it has to bear, in a design such that all parts are harmoniously related to the production of certain results, represents an ideal toward which the designer may well strive with all his energy.

#### Plan of Organization of a Taxicab Company.

BY EDWARD WELLS.

In this article the whole organization is shown as divided into three separate departments, executive, managerial and operative, while the subdivisions of each are clearly designated.

#### EXECUTIVE DIVISION.

First in authority comes the executive division, which is made up of the usual corporation officials, whose relative positions are as follows: President and board of directors, vice president, treasurer and secretary. The duties of the executive officials are clearly indicated in the bylaws of the company, and they will, of course, be governed by the laws of the State relating to corporations, and the responsibilities and duties of officials connected therewith in the handling of the affairs of the company.

#### MANAGERIAL DIVISION.

General Manager.—First in authority in the managerial division will be the general manager, and he will have full control over the entire company as to management and operation, excepting that problems of vital importance and affecting the whole policy or welfare of the company will be referred to the board of directors for approval before taking effect. The general manager, who will also be the vice president, will countersign all checks and, in general, outline the business policies of the corporation. No expenditures will be made without his approval, excepting as hereinafter outlined, and all important contracts must also be submitted for his approval and signature.

Assistant General Manager.—Next in authority will come the assistant general manager, who will be in active control of the managerial division and have a general oversight of the operative division. He will be advised or directed in matters of great importance by the general manager, and, in the absence of the general manager, will confer with the board of directors in such matters. While the assistant general manager will not handle the actual cash of the company (which will at all times be under the direct control of the treasurer), he will nevertheless have general charge of

various papers and documents relating to expenditures or receipts, and no requisitions for supplies or other orders calling for disbursements or payments of any sort will be valid except when O. K.'d by him or by the general manager, as previously specified.

The assistant general manager will apportion the work and daily duties among the various other members of the business department, and will have full charge of the same. He will design, change or modify systems pertaining to the business according to his discretion. He will also certify to the correctness of all payrolls and O. K. all purchase requisitions (as heretofore mentioned), and approve all reports of receipts when the same are audited and found to be correct. He will also inspect all other reports from every department of the company and approve the same if found to be correct, and in accordance with the requisites of the business. Other duties of the assistant general manager will develop as the business progresses, and he will, of course, fulfill these in accordance with his judgment and discretion.

At all times the managerial division will have jurisdiction over the operative division, but, unless some serious contingency should arise, it is understood that the authority of the superintendent will not be superseded, and in any and all cases where changes are thought advisable in the operative division the superintendent must be duly notified and such changes made through him.

Assistant Treasurer.—The assistant treasurer will be in charge (under the treasurer) of the direct collection and disbursement of the company's funds in all departments and will sign all checks and have charge of the bank accounts for all operative and current uses. All checks, however, must be countersigned by the vice president and general manager, as hereinbefore stated, or in his absence by whoever the board of directors may designate. The actual collections of cash will be made by the paymaster and collector, who will immediately

turn them over to the assistant treasurer, obtaining a receipt from him for the same, and he will also apportion and disburse all salaries of employees of the operative division according to the O. K.'d payrolls which will be furnished him by the management; and for this purpose he will receive the correct amount of cash from the assistant treasurer, giving him a receipt for the same, which receipt will be returned to the paymaster upon his delivery to the assistant treasurer of the signed payrolls or other salary receipts covering the disbursement of the amount previously delivered to him.

The assistant treasurer will issue "petty cash" (so called) to the cashier or bookkeeper, who will expend the same for office incidental uses, such as for postage stamps. express charges, telegrams, stationery items of not more than \$1 in each case (larger expenditures must be made by requisition only), and for such other incidental uses as may be directed by the assistant general manager. In all cases the assistant general manager must O. K. every petty cash voucher, and the account must be balanced, and if found to be correct approved by the treasurer or assistant treasurer when amounting to not more than \$25. The assistant treasurer will have authority over the paymaster and collector in matters relating to the handling of cash, but in all other respects he will be under the managerial division only.

The treasurer and the assistant treasurer will at all times have access to the cash books and payrolls of the company, as well as to any documents or other papers pertaining to the receipt or disbursement of the company's funds.

The assistant treasurer will also make up all payrolls in accordance with the detail furnished him by the time clerk, which must be approved by the management before becoming authoritative. He will also act as auditor of all accounts.

The collection of "change accounts" with the various stands at which cars of the company are stationed will also be included in the duties of the assistant treasurer, and to facilitate such duties he will have a certain amount of authority over the bookkeeper, such as causing statements, etc., to be sent. This will also be so in the matter of monthly or other accounts with individuals who lease or secure cars upon the rental basis. It will thus be seen that the statistical or bookkeeping department is under the managerial authority in all respects, excepting such as relate directly to the handling of cash or the collection of ecounts, which will be authorized by the treasurer or his assistant.

Paymaster and Collector.—The paymaster and collector will receive the collections of an "starters," making a daily trip to each stand, where a starter is stationed for this purpose. He will receive all moneys collected from stations where there are no starters from the chief starter, who in turn will collect the same from the chauffeurs

assigned to such stations. The starters will be under the collection agent only in regard to the handling of funds received, and in all other matters will be under the authority of the superintendent or the managerial division through the superintendent.

All salaries, except those of the employees of the operative division (who will be paid by the cash envelope method), will be paid directly by check by the treasurer or his assistant. The assistant treasurer, paymaster and collector and all starters will be required to furnish surety bonds.

Advertising Manager.—The advertising manager will be under the authority of the assistant general manager, and will be in full charge of all matters relating to advertising. In case the advertising is placed in the hands of an outside advertising agency (which may be done at the option of the board of directors of the management) this branch of the business will nevertheless remain under the direct supervision of the assistant general manager, who will delegate stenographers or other office employees to assist the advertising manager to such an extent as in his judgment may be sound necessary.

Chief Clerk.-The chief clerk will have charge of the office employees (with the exception of the bookkeeper) under the assistant general manager, and his duties will include an oversight of stenographic work. tabulation of reports and the general details pertaining to the statistical work of the company. He will open such mail as may be designated by the assistant general manager, and in the absence of the latter from the office will assume such of his duties as may be designated by the general manager. The chief clerk, however, will have no authority at any time over the operative division, and in the absence of the assistant general manager only the general manager will have authority over the head of the operative division.

Minor Office Assistants.—The duties of stenographers, filing clerks and telephone

operators will be according to custom and to the requirements of their several positions as relating to this line of business. They will all be under the control of the assistant general manager and the immediate direction of the chief clerk.

Bookkeeper.—The bookkeeper will attend to the usual duties of such, and will be under the authority of the assistant general manager in all matters excepting those hereinbefore specified as coming under the authority of the treasurer or his assistant.

In the event of its being found necessary to create other offices or to engage employees not specified in the foregoing the respective positions and duties of such will be determined by the board of directors, in the event of the positions being those of authority, or by the assistant general manager, in the case of minor employees or office assistants.

#### OPERATIVE DIVISION.

Superintendent.—The superintendent and chief engineer will have control of the entire operative division, excepting that he will be subject to a certain amount of authority of the managerial division, as previously specified. He will issue general directions for the guidance of the assistant superintendent, inspectors, foremen, master mechanic, starters, head tireman, time clerk and all other employees of the operative division.

All requisitions for gasoline, oil or other supplies or materials of any nature whatever, necessary for use in the operative division, will be made by the superintendent, but must be O. K.'d by the assistant general manager and approved by the general manager, as previously stated.

The superintendent will also see that all fire regulations and other ordinances relative to personal or property protection are strictly enforced, and will conduct such examinations, tests or drills as may be necessary for safeguarding the same.

All operative department pay rolls or reports of an important nature must be in-

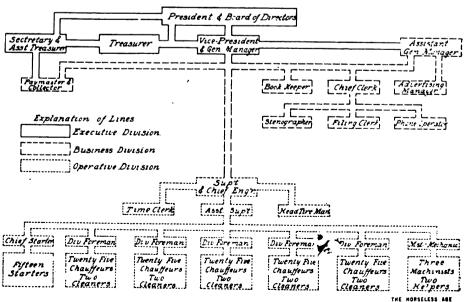

DIAGRAM OF ORGANIZATION.

spected by the superintendent before being submitted to the managerial department.

Assistant Superintendent.—The assistant superintendent will act as a general assistant to his chief, aiding him in all matters relative to the immediate handling of the various minor authorities of this division, and will have direction of the daily routine work at the garage. Among his principal duties will be the dispatching of the cars upon the various "shifts," which will be done according to the running schedule furnished by the management.

He will also have charge of the issuance of supplies to the chauffeurs and garage men, and will act as custodian of the gasoline, oil, spark plugs and other valuable supplies necessary to this department. He will be required to give an accurate accounting for all supplies so dispensed, and will use the strictest economy regarding the same. The superintendent will, of course, have a general oversight of the supplies utilized as well.

Division Foremen.—Division foremen will each have charge of a certain number of cars (probably twenty-five), and the chauffeurs running these cars will come under the direct authority of the respective foremen. Two or more car cleaners will be placed under the direction of each foreman, who will bear the responsibility that their work is done properly. Foremen will also be required to make a general inspection of cars in their respective divisions, according to the detail which will be required by the superintendent, and to promptly report to the superintendent, his assistant or the master mechanic any defects found to exist, so that the same may be remedied promptly. In case of "tire troubles" foremen will report the same directly to the head tireman, who will forthwith cause the defective tires to be replaced.

Foremen will probably be required to act as substitute drivers in cases where the regular drivers are off duty, according to the discretion of the superintendent. They will render whatever assistance may be possible toward the maintenance of the proper discipline and satisfactory operation of the department. Foremen will have no authority over the starters, who will report directly to the superintendent, his assistant or the collector, as stated.

Master Mechanic.—The master mechanic will be in charge of the repair department. and will have under his authority a sufficient number of machinists and helpers to keep the rolling stock of the company in proper repair at all times. He will report directly to the superintendent or his assistant, and any materials or supplies that may be necessary for this department will be ordered by requisition, and he will be required to give a detailed accounting of the distribution or application of any and all supplies and materials so ordered. The master mechanic will report the progress of work in his department according to the system which will be prescribed by the management.

In charge of the master mechanic will be a corps of capable inspectors, whose duties will consist of making regular and careful inspections of all cars, with a view to detecting any possible defects or imperfect adjustment, which must immediately be remedied under the direction of the master mechanic. These inspectors must all pass a rigid examination, which will be conducted by the superintendent before they will be allowed to assume these duties.

Time Clerk.—A time clerk will be employed, who will report the arrival and departure of all cars at the garage, the number and names of the drivers thereof, whether substitute or regular, and upon his weekly report, approved by the superintendent, will be based the payroll of the operative division. The time clerk will obtain data concerning the employees of the repair department from the master mechanic, and the superintendent will designate someone to assist him in the "checking in and out" of cars during the hours when he is off duty.

Head Tireman.—As this company will lease the tires upon the mileage basis, the head tireman will probably be an employee of the tire company. He will, however, be subject to the authority and rules and regulations that apply to the authority of the superintendent, and to rules and regulations that apply to regular company employees. He may have one or more assistants if the superintendent deems this necessary, and will have charge of the replacing and repairing of tires. A tire storage room will be supplied at the garage, and only the tiremen and those in authority above them will have access to this room.

Chief Starter.—The duties of chief starter will consist of directing the movements of the chauffeurs of all cars stationed at locations where no regular starter is maintained, and all collections that are made by such chauffeurs will be turned over to the chief starter, who will give the chauffeurs individual receipts for these amounts, and will in turn hand this money over to the collector, obtaining a receipt from him for the same. He will compare the meter readings of these cars with the daily reports, which will be turned in by the chauffeurs thereof, and will make detailed reports pertaining to the same according to the requirements of the management.

All other starters will be stationed at the various "stands" of the company, and will receive the moneys collected by the chauffeurs whose cars run from these respective stands, as stated. They will compare the meter readings of these cars with the daily reports which will be made by the drivers, comparing their own report sheets therefrom, which they will hand to the chief starter, and which will constitute a part of the general detailed report that he will be required to furnish to the management.

A counter-checking system will be employed, the requirements of which must be faithfully complied with by all starters and chauffeurs, and which will render it im-

possible for any dishonest practices to exist. The duties of chauffeurs, inspectors, cleaners and other assistants will all be in accordance with the requirements of the business; each of these employees will be furnished with a copy of the rules and regulations of the company, and they will be required to comply strictly with the same.

Chart.—The accompanying chart will give a good general idea of the organization of the taxicab company, with its subdivisions and with the authorities and responsibilities of the officials connected therewith clearly designated. Should it be found necessary or deemed advisable by the management or board of directors to make any important changes in this report or the recommendations contained therein, a supplement showing such changes or modifications should be appended hereto.

It is intended that a copy of this organization report shall be furnished to each prominent official of the company, and in case of minor officers a summary of that portion of the report pertaining to their individual position and the duties connected therewith will be given.

#### Reminder of Lamp Lighting Time.

Most of the State automobile laws have a clause giving the time at which lamps shall be lit, as well as specifying their number, position, etc. The time at which lamps must be lighted has generally been one hour after sunset. Under these circumstances the actual need of illumination generally causes the driver to light up at an earlier period than required by law. However, the new Massachusetts law sets the time at one half hour after sunset, and the police of many of the towns and cities enforce this clause quite rigidly. On this account the Boston Athletic Association introduced an idea which might well be copied by garages and automobile clubs. It consists of posting in the garage a small black board on which is painted "Light Auto Lamps at," a space being left where the time and the date may both be entered. This latter feature is a good one, for the reason that in case of neglect to post the time from day to day, one can easily make the proper allowance. Furthermore, some one is almost sure to remind the office of any remissness in this respect,

The German Imperial A. C. has decided to postpone its reliability contest for small cars until next spring, in accordance with wishes expressed by a majority of the entrants.

Dr. Levin-Stoelping, a prominent member of the German Imperial A. C., who represented that club at the last convention of the recognized automobile clubs, died of heart disease recently at the age of forty-five. He was a member of the executive committee of the club, and during his last years he devoted his whole efforts to its work.

#### The Manufacture of Bevel Gears.

By F. E. WATTS.

The following matter is descriptive of the practice of the Vulcan Gear Works, of Detroit, and was obtained through the courtesy of T. F. Ahern, treasurer of the Modern Machinery and Engineering Company, of Cleveland.

The Vulcan Gear Works specialize on the production of bevel differentials and driving gears. The material used for the differential gears and pinions and for the driving gear is carbon steel running from twenty to thirty points carbon. While reasonably high in manganese, it machines rather freely. The driving pinion is made from nickel steel. All the gear blanks are drop forged.

The blank for the large bevel gear is approximately the shape shown in the sketch Fig. 1. It is first chucked by the outside and the hole B is bored and reamed. At the same time the surface A is faced. The reamer used is an ordinary milling cutter with the corners of its teeth slightly rounded on the entering end. This work is done in a Potter & Johnston 81/2x16 inch automatic. One hundred and twentyfive blanks are machined on these surfaces in ten hours.

The blanks are next taken to a multiple spindle drill, where eight holes for the attaching screws are drilled. The drill is a Rockford, and is an ordinary single spin-

The teeth are now roughed out to within about one sixty-fourth of the finished size, with stocking cutters in a Brown & Sharpe

The teeth are produced in the same manner as those for the driving gear.

The blanks for the driving pinion are produced in a large LeBlond lathe with compound rest. The tapered hole and key seats are finished first, leaving the blank

FACING A DIFFERENTIAL GEAR BLANK.

machine. This operation is performed rapidly with a liberal supply of lubricant. Having removed most of the stock in this manner, the finishing cut is taken in a Gleason "generator." This completes the

machine work on the gear. The differential gear blanks, shown in

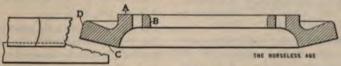

FIG. 1.—DRIVING BLANK AND ROUGHING TOOL.

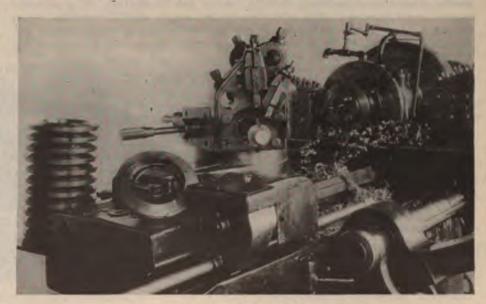

dle drill fitted with a multiple head, which drives the individual drills by spur gears and idlers. The table is made as shown in Fig. 2, to carry away the lubricant. This is copiously supplied through a ring of gas pipe, which surrounds the drilling head, an individual pipe leading down from this header to each drill. The holes are drilled to within a thirty-second of the required size and then finish drilled, so that there is little chance of the drills "running out" in the finishing operation.

After drilling the blanks are taken to another Potter & Johnston "automatic" and chucked by surfaces A and B. They are driven by studs in the drilled holes. Faces C and D are now machined as shown in Fig. 1 and in the photo. Roughing tools work on one side and finishing tools on the other. The faces of the roughing tools are grooved to break up the chips. They work on the side of the work which is coming down while the other tools cut on the opposite side, where it is turning up. The blanks are turned very close to size. The limits being controlled by gauges, made from sheet metal about 3-16 inch thick. An average day's work of ten hours finishes seventy blanks on faces D and C. The outside diameter is between 9 and 10 inches. This operation finishes the blanks.

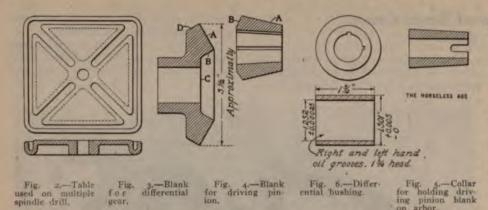

Fig. 3, are also finished on P. & J. automatics. Surfaces A, B, C and D are machined, by the tools shown in the photo, on a No. 5A special machine. The hole and the other end of the hub are finished on one of the large automatics. The output for each machine is 100 in ten hours.

as in Fig. 4. The collar Fig. 5, is slipped in the blank and it is mounted on the arbor, being driven by a half key. Face B is then finished and finally face A. Each of these faces is given the proper angle by feeding the compound rest in by the automatic attachment shown in the photo.

This attachment was made in the shop, and though very simple does the work nicely. It was made as follows: A ratchet bit brace was purchased and the handle straightened out, cut off, and threaded. A new ratchet wheel, with twice the number of teeth of the regular, was cut and attached to the operating spindle. The threaded lever was attached to a crank on the edge of the feed pulley by means of a wire cable passed around two pulleys fastened to the roof overhead. This served to pull the ratchet lever upward. It was pulled down to give the feeding movement

FACING DRIVING GEAR BLANKS.

by a spring attached to the floor. By relieving the operator from the strain of feeding this attachment has increased the output so that from ninety to one hundred blanks may be faced on surface A in a day, and from one hundred to one hundred and twenty-five on the back surface B in ten hours. A small crank is used to feed the cutter rapidly back by hand after a cut is finished. A slightly different class of work is represented by the phosphor bronze bushing for the differential, shown in Fig. 6. The dimensions show what close limits are used where it is desired to reduce the work of assembling.

The bushings are cast with an end of slightly larger diameter for chucking. They are held by this end in a three jaw chuck, placed in the small P. & J. automatic. The first operation is roughing the inside and outside surfaces. The second is to finish-turn the inside and outside, face the end and slightly round the outer corner, so that the bushing will force into place easily. The third is to cut the right and left hand oil grooves. This is done by a threading tool, which cuts the right hand spiral when it goes in and the left hand when it comes out.

The fourth operation is a quick reaming, which removes the slight burr left from machining the oil groove. The fifth is the cutting off. As the cutting off tool is feeding in an arm of the turret, carrying a wire, is fed forward so that when the bushing is cut off it hangs on this wire and is carried out of the way by the next turn of the turret. It can then be removed by the operator after he has chucked the next bushing. One hundred and fifty bushings are completed in ten hours. When we consider that this includes the spiral oil grooves the time will be seen to be remarkable.

A far more interesting piece than either of those described is the housing for the differential gears. In the production of this piece eight tools are used at the same time. This process will be shown in a later article when photos are available.

The American Carriage Builders' Association will hold their thirty-seventh annual convention in Washington, D. C., during the week of October 18. In connection with the convention there will be an exhibition.

#### How to Prevent Injury from Engine Back Kicks.

BY ALBERT L: CLOUGH.

Accidents to persons starting automobile motors continue to be lamentably common in all parts of the country, and their frequency and seriousness are such as to require the careful attention of all who have the good name of the motor car at heart.

These accidents are of two classes, those in which a "back kick" of the motor breaks the operator's arm or otherwise injures him and those in which not only the motor but the car starts when cranking is performed, and the operator is run over or crushed between the car and some stationary object.

As preventives of the first class of accidents the use of an automatic device to prevent the engagement of the starting crank unless the spark position be sufficiently retarded has often been advocated in these columns.

In the absence of such a device the marking of the safe starting position of the spark lever upon its segment and the adoption upon all cars of a uniform practice as to the form and position of the spark control segment, and as to the direction of lever movement to effect advance and retardation, would offer a measure of protection to persons cranking cars with which they are not specially familiar. The adoption of an automatic spark time governor would also be effective. As a preventive of the second class of accidents, arising from the cranking of engines while a gear is in mesh, the use of a safety device ren-

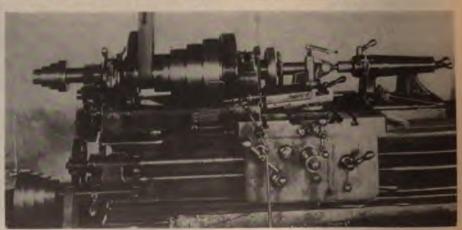

dering it impossible to engage the starting crank unless the gear level is in neutral has been repeatedly urged. Unless both these suggested safety appliances are in use the careless operator is likely to meet with an accident of one or the other kind.

The most obvious preventive of cranking accidents is the entire elimination of the cranking operation, by the provision of seat starting arrangements. If no one is at the crank when the motor makes its first explosion, no one can be hurt, even though the gears be in mesh. A motor starter of the compressed gas type eliminates all danger of this kind and the ability to start a motor "on the spark" does so very largely.

As a very large proportion of the motors now in use are of the four cylinder type, most users can take advantage of starting from the seat if they have a battery system either as regular or auxiliary equipment. Practically any four cylinder engine. even though it will not "spark off" after a long period of idleness, will do so almost infallibly immediately after fresh charges have been drawn into its cylinders. In order to secure immunity from cranking dangers, the operator should crank the motor a turn or two with the spark off, priming the carburetor if need be, then enter the car and throw on the switch from the seat, manipulating the spark lever if necessary. A motor in any sort of condition will start under these conditions, and the procedure involves no danger of a back kick or of being run over,

In the case of cars equipped with ordinary magneto ignition only this procedure of course cannot be resorted to, and cranking accidents may be expected to be more common with such cars than with those fitted with batteries, unless a spark time governor be fitted to the magneto. However, it is probably but a matter of a short time before seat starting provisions will be applied to magnetos—a beginning having already been made in that direction.

It is confidently believed that the adoption of the practice of cranking motors with the spark off and starting from the switch will greatly reduce the number of accidents now occurring.

TURNING A DRIVING PINION BLANK IN A LATHE.

#### THE HORSELESS AGE

Founded in 1895 by E. P. Ingersoll. 9-15 Murray St., New York. Every Wednesday.

Publishers:

Fred J. Wagner,

Charles B. Ames.

EDITORIAL STAFF.

Subscriptions (payable in advance), Domestic, \$2.00 a year; Canada, \$3.00. All other foreign countries included in the Postal Union, \$4.00. Single copies, 10 cents.

BRENTANO'S, 37 Avenue de l'Opéra, Paris.

COMMUNICATIONS .- The Editor will be pleased to receive communications on trade topics from authentic source. The correspondent's name should in all cases be given as an evidence of good faith, but will not be published if specially requested.

Address all communications and make all checks, drafts and money orders payable to THE Horse-LESS AGE, 9-15 Murray street, New York.

Entered at the New York post office as secondclass matter.

One week's notice is required for change of advertisements.

Telephone: 7195 Barclay. Cable: "Horseless." New York and London. Western Union Code.

#### A Word as to Future Policy.

As the papers for the transfer of THE Horseless Age were signed only just before last week's issue went to press, it was impossible to give in that issue more than the mere announcement of the change in ownership. When such a change occurs the readers of a publication naturally expect an outline of the policy under which the paper is to be conducted in the future. Old supporters of THE Horseless Ageand there are names on our subscription lists that have been there since the first year of publication-will be pleased to learn that the editorial policy will continue substantially the same as in the past. The chief aim of the editorial staff will be the presentation of material of direct practical interest to the readers of the paper. Utility will be the keynote of the editorial pages in the future as it has been in the past.

THE HORSELESS AGE is now being read by practically every competent technical man in the industry, and as a purveyor of sound technical automobile information we believe it has no peer the world over. It been of the opinion that many devices or

will be the aim of the new management to maintain the high standard in this respect which has been set in the past. The hundreds of practical men in the trade and in the industry whose writings have in the past been placed before an appreciative circle of readers through our columns are invited to continue their collaboration in the future. What we wish particularly is matter based on original investigation or observation in the factory, the laboratory, the shop or on the road.

Aside from the purely technical matter, which at this late day in automobile engineering to be of value must necessarily be of a highly specialized character, increased attention will be paid to the needs of the automobile owner. A series of articles from owners whose training and inclinations fit them particularly to comment on practical automobile topics forms one of the features contemplated for the near future. The Maintenance and Repair Department, which has been a regular feature of the paper for years, will be strengthened; all the other regular departments will be maintained, and in addition we will publish original illustrated reports of all automobile happenings of importance. A paper of the class of THE HORSELESS AGE offers this advantage to the owner in quest of helpful practical hints, etc., that everything appearing in its pages passes the scrutiny of the most expert automobile men in the country, who count among its readers, which is the greatest incentive to watchfulness against misstatements in the first place, and results with almost unfailing certainty in the discovery of any error that may slip through, and its immediate correction. This is a point of no mean importance at a time when so much garbled auto literature is being circulated.

It is not necessary to go further into details. We do not ask you to accept our promises, but to watch our performances. In conclusion, however, we wish to say that the same high editorial standard will be maintained as in the past, and more energy will be put into the conduct of the paper, which we feel certain will insure the rapid growth and improvement of THE HORSE-

#### Cup and Cone Ball Bearings.

The cup and cone (or bicycle) type of ball bearing furnishes an example of a method of construction having been readopted after having once been almost entirely discarded by an industry. We have always

methods of construction that were used and discarded in the early days of the industry would prove much more satisfactory now if applied in the light of the experience of recent years. The bicycle type of ball bearing did not prove very satisfactory in the early steam cars, but that may have been due to the use of too small balls or of balls of inferior material. The fact that it is capable of giving good service even on fairly heavy cars is proven by the fact that it was used quite extensively, until recently, on the make of cars which has won the Glidden Tour six years in succession. It will not be denied, we believe, that the cup and cone bearing is not as fine a type as the modern annular ball bearing; for one thing, it does not possess the fool-proof character of the latter. But it possesses considerable merit from an economic standpoint, as the cups can be produced in the press, and the other parts do not require the same accurate machine work as does an annular bearing. The manufacturing cost of the cup and cone bearing is therefore comparatively low, and this type of bearing appeals particularly to manufacturers of low priced cars, in which the expensive type of bearings would be out of the question.

In the present issue we publish an article on the design and manufacture of the cup and cone bearing, by E. J. Bartlett, We believe that this is the first thorough technical treatment of the subject as applied to automobile work, and feel sure that the article will be read with interest and profit by numbers of our technical readers.

#### Smoky Taxicabs.

If there is any type of car in which a controllable but fool-proof lubrication system is more necessary than in another it is the taxicab. When a car smokes badly on a country road, where there is little traffic, it does not cause much annoyance to anybody, but taxicabs are in continuous use in the centres of street activity in our big cities, where a car belching forth clouds of blue oil smoke constantly offends the eyes and the nostrils of many persons. We have seen crowds collecting in New York city around taxicabs standing at the curb which were pouring out such volumes of smoke that the street gamins evidently thought the car was on fire,

As is well known, the New York Park Board enforces a rule prohibiting smoking automobiles in the parks, which is in itself a very strong incentive to provide taxicab motors with an oiling system that cannot

go wrong. It is, moreover, to be feared that unless the manufacturers of the cabs and the operating companies use the strictest caution the city authorities will also legislate against smoking cars in the streets.

It has been claimed that the park ordinance against smoking cars was the direct result of offenses of taxicab drivers in this respect. The cab chauffeurs, owing to the lower wages paid them as compared with drivers of private cars, are not of the same competence as the latter, and especially during the introductory period were many unskilled drivers employed. It appears that for one reason or another these neglected to give the proper attention to the oiling system of the motors, with the result that cases of damaged bearings and scored cylinders were rather frequent. The company then issued orders to use oil liberally, and the result of this was that taxicabs gained rather an unenviable reputation as "smoke wagons."

In the design of the motor lubricating system for a taxicab account must be taken of the serious objection to overlubrication in these vehicles, and of the fact that the drivers are ordinarily not mechanics and are frequently rushed all day long, which makes a system requiring much attention from the driver unsuitable. If the system of mixing the lubricant with the fuel can be used with the same degree of success in four cycle motors as in two cycle motors it would seem to have much to recommend it for taxicab use, as it would relieve the drivers of all responsibility with respect to motor lubrication, and at the same time insure at least a fair degree of smokelessness.

### A Development of Vehicle Lighting.

A method of incandescent lighting, by means of the complete combustion acetylene flame, directed upon a button of refractory material, is at present being introduced as a substitute for the ordinary luminous flame method generally employed in automobile searchlights. The arrangement is, in principle, a Drummond or calcium light, an acetylene air flame being employed instead of an oxyhydrogen flame, and the incandescing button being possibly of some other material than the quicklime or "calcium" used in the conventional lime light.

It is a fact that gas lighting devices, which depend upon the raising to incandescence of a suitable light giving solid, wher the heat of a gas flame burned upon the Bunsen principle, are generally more efficient than those of the simple flame type, in which the light is produced by the transient heating of particles of carbon in a gaseous mixture, containing too little oxygen for complete combustion.

Attempts have been made to apply to automobile searchlights the Welsbach mantle type of burner, which furnishes a good example of the high gas economy realized with the incandescent method, but the fragility of the mantles has prevented the application from attaining commercial success. It may be presumed that the button form of incandescent body may be made sufficiently rugged to meet the severe requirements of automobile service, and, as the light in a projector is only required to be radiated in a restricted horizontal arc, the button form of light source would seem to be well adapted for the purpose.

Judging from general experience in illumination, the useful light obtainable from a given quantity of gas, used in an incandescence burner of this type, may be expected to be very substantially greater than that from the same quantity of gas burned in the ordinary luminous flame for two reasons: In the Bunsen flame used in the incandescence burner, all the thermal energy in the gas is set free, and no carbon escapes unconsumed. Furthermore, the incandescing body may be of such a nature as to possess a higher luminous emissivity than the carbon particles which afford the light of the open flame burner.

#### The Parts Famine.

For some time it has been apparent that the automobile production for 1910, instead of being limited by the buyers' demand, or by the capacity of the vehicle factories, will be limited by the capacity of the parts factories. For months representatives of newly organized assembling firms have been scurrying over the country with the object of placing orders for engines, transmissions, axles, steering gears, etc., and it is in general very difficult to get promises of prompt delivery. New companies to assemble cars have been organized at an unprecedented rate during the past several months, while there has been no particularly noticeable activity in the organization of parts manufacturing companies until quite recently. Nevertheless the auto parts industry has grown considerably during the past year by the entry into it of many old established machinery

concerns. As a general thing these concerns first accept orders from large automobile manufacturers for parts according to the latter's designs and specifications, and after some experience in auto work has been gained in this way the concern branches out by getting up its own designs of parts for which it solicits orders from assemblers.

The many recent defections from the general machinery industry to join the auto parts industry have caused some little anxiety in the former industry, it would seem. Thus, the *Iron Age* observes that "the departure may be too radical to be wise. Enthusiasm," it says, "for the new product may mean the neglect and serious injury of the old. At present the sucessful automobile part brings the handsome profit which a specialty usually commands. But, as with every other business, the time must come when competition will get down to the normal basis, with profits reduced to the usual level."

Whether the move proves a wise one or not will probably depend upon the particular company and the condition of its previous business. The fact is that automobile manufacturers must have the parts and are willing to pay liberal prices for them, which is generally a sufficient inducement. As most of the new parts firms confine themselves to a limited line of products, and as the cost of the necessary special equipment can be closely calculated in advance, the risks involved are not so great. Undoubtedly all firms that enter the parts industry realize that the present market conditions will not be permanent, but they consider that even after the readjustment of supply and demand the auto parts field will offer as good. if not better, chances as the general machinery field.

#### Pamphlet on Corporation Tax Law.

Henry W. Brooks, Jr., & Co., 15 Wall street, New York, have issued a pamphlet regarding the new corporation tax law, passed by Congress, together with the tariff law, which is applicable to practically all corporations earning over \$5,000 net, as nearly all corporations do an interstate business. The pamphlet explains the method of arriving at the so called net income, which is said to be not in accordance with the manner in which corporation books are kept. Copies of the pamphlet will be sent free of charge upon request if The Horseless Age is mentioned.

Arrangements have been made whereby 300 taxicabs will be placed in service in the streets of Vienna, Austria, by next summer

#### Cup and Cone Bearings.

By E. J. BARTLETT.

The cup and cone or bicycle type of ball bearing has remained practically unchanged since the days of the bicycle, and, later, the early automobiles. With the increase of power, weight and price of the popular types of cars and the advent of the more efficient and more expensive anti-friction bearings, the cup and cone bearing suffered in popularity.

While a comparatively few manufacturers have adhered to this bearing, at least in part, many have regarded it as unsuitable for automobile use. Recently, however, there has seemed to be a renewed interest in the cup and cone bearing, as the demand for cheap and medium powered cars has increased. The majority of the popular 30 horse power, 2,500 pound runabouts and light cars now being manufactured in such large quantities are equipped wholly or in part with this bearing, and it is not unreasonable to suppose that the coming season will see its broader application, as the tendency seems to be toward even cheaper and smaller cars of this class.

With the legitimate popular demand for cars with some kind of anti-friction bearing equipment, its relatively low cost and durability make it one of the logical bearings for cars where cheap and fairly efficient bearings are a necessity. It is also adaptable to a wide range of service conditions, carrying both radial and thrust loads, with approximately equal effectiveness, which feature is found only in the more expensive tapered roller and double annular bearings. It is thus readily seen that for cheap cars its low cost makes it preferable, in competition, to the two types of bearings above mentioned, as well as the expensive annular bearing, while its ability to carry side loads, without the aid of separate thust bearings, gives it important advantages over the cheaper straight roller bearings.

Aside from the relative cost, there seems to be a growing tendency to prefer the cup and cone bearing, when well made, to the annular bearing, where there is considerable side thrust, which the annular bearing has been supposed to be able to carry as the bearing of a front hub.

#### DESIGN.

Fig. 1 shows a typical cup and cone bearing. The race is made of a steel stamping, with its smaller diameter curved in as shown to form a support for the balls when not in place on the cone. A groove on the inside near the edge forms a seat for a stamped split annular retaining ring, which holds the balls in the race before assembling on the cone. In some of the earlier bearings the retainer and lip on the race were omitted, thus making it more difficult to assemble.

This is necessarily a "home made" bearing, or, at least, a home designed bearing, as no manufacturer, to the writer's knowl-

edge, makes a complete line of bearings for the market. For this reason each designer must select his own sizes, materials and mountings, as there is no handy manufacturer who has made a specialty of this work of whom to ask advice. As an aid to selecting the proper sizes Table I is given covering the sizes ordinarily used in automobile work.

In laying out the sizes of a cup and cone bearing equipment it is practically impossible to be governed entirely by the loads the bearings will have to carry, as very few conditions exist where these loads can be accurately computed. Usually some precedent or former experience of the designer is a far better guide. At the present time there are plenty of satisfactory bearing equipments established of any of the recognized standards for all ordinary purposes, and such precedents, tempered with common sense, will produce better results than any theoretical calculation.

As a general proposition, it is better to select a rather generous size of ball for a cup and cone bearing, as the material is probably not as good as in a high grade

tive manufacturers of the different types of bearings.

#### MATERIAL AND CONSTRUCTION.

The material generally used for the cups and cones is a good grade of carbon steel of the following analysis:

- .12 to .18 carbon.
- .20 to .30 manganese.
- .04 or below sulphur.
- .04 or below phosphorus.

As the cones get the harder service, owing to the smaller area of ball track, some manufacturers use a special cone steel. Nearly all the large steel manufacturers have a special kind of steel for this purpose sold under various trade names. A typical analysis of such a steel, which gives rather better results than the plain carbon steel mentioned above and which is also more expensive, is as follows:

- 1.05 to 1.10 carbon.
- .25 to .35 manganese.
  .15 to .20 silicon.
- .025 or below sulphur.
- .025 or below phosphorus.

The balls generally used are of a good grade of case hardening steel made from the bar, and carefully hardened, ground and sized. Some manufacturers prefer forged balls, but while these may be superior to the balls made from the bar, so far as pit-

special bearing, and it is doubtful if the workmanship will be as good. If the equivalent size of an annular bearing is known a rough rule, which the writer has found satisfactory, is to select a ball diameter one size larger than used in the annular bearing for radial loads only, and two sizes larger if there is a radial and thrust load combined. It is not always possible or desirable to follow this rule absolutely, as the conditions of mounting, such as the diameters of shafts or hubs of the differential, necessitate a size of annular bearing other than that required by the load. This is a point in favor of the cup and cone bearing, as it can readily be made to suit the mounting conditions, and in this respect it is very flexible and requires less adapting parts.

To show the comparative bearing equipments used in practice, Table II is given. The equipments are for axles suitable for the popular type of 1910 cars of 25 horse power to 30 horse power, weighing empty from 2,000 pounds to 2,500 pounds, and are largely those recommended by representa-

ting is concerned, they seem more liable to split, due to flaws in the forgings.

A better and more expensive ball is made from alloy steel. Such balls may be procured in this country, but the Hoffman ball,

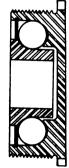

FIG. 2.—ADJUSTABLE BALL CUP.

which is made abroad, is frequently used where the very best cup and cone bearing is desired.

The ball cups are generally made from a steel stamping, as shown in Fig. 1, unless some function other than the bearing is

required, such as an adjustment. In such cases the cups are made from bar stock. It is sometimes possible to save in the number of parts by a very little additional expense, and complication in the cup. Such a construction is shown in Fig. 2; the threaded and castellated portion allows adjustment without the use of additional parts.

The ball track may be either polished or ground, the latter method giving the better results, as the track should then be true and concentric with the cone. A cheaper method often used, especially with the pressed cup, is to polish the track when soft and again after hardening, the first polishing, when soft, removing any surface roughness and making the final polishing operation, after the cup is hardened, easier. This method gives a very nice, smooth surface, but one which is not necessarily concentric with the cone. By careful hardening methods the distortion, due to hardening, may be overcome to a large extent, and with thin pressed cups it is possible to correct some at least of this distortion when pressing them in their seats, if the wall of the seats is heavy enough, so it in turn will not be forced out of its proper circular shape. In other words, it is possible to produce a good cup without grinding if all the conditions are right, but it seems a more dependable method, and in the end as cheap, to grind both the outer diameter and ball track, and polishing the latter to a smooth surface.

Both the bore and the ball track of the cone should be ground after hardening, and the track polished. By hardening the cones on plugs it is possible to keep them very true, and they take but little grinding to produce good results.

Both the cup and cone should be hardened in the ball tracks at least one-thirtysecond inch deep, to prevent the surface hardness breaking through.

As with the cup, it is sometimes desirable to combine the cone with some adjacent part. Fig. 3 shows a cone made a part of a drive pinion.

#### MOUNTING.

Since the cup and cone bearing is not self contained, it may be adjusted for wear (a desirable feature), and either the cup or cone may be mounted in such a way that it may be adjusted. Where possible it is

FIG. 3.—CONE AND PINION MADE INTEGRAL.

preferable to make the cone a press fit on its shaft or hub, and adjust by the cup, since the bearing area is greater. In some places this cannot be done conveniently. and the cone must be the adjusting member. In such cases it should not be left loose, as there is danger of the balls binding and causing the cone to turn on its support. A common method of securing cones against turning on their support is to drill a small hole in the end or cut a small slot at the inner heavy corner, as shown in Fig. 1. A pin fast in some adjacent part or driven in the shaft and projecting in the hole or slot in the cone will then serve as a lock. Such pins should be about threesixteenth inch in diameter, and made of drill rod rather than cold rolled steel, which is a softer material. In a hub, for instance, both cups would be tightly pressed in their seats; the inner cone pressed on the spindle, the outer cone loose on the spindle, but secured against turning by a pin held in a tongue washer placed between the cone and spindle nut. One of the inherent defects of this type of bearing is the possibility of it being carelessly adjusted. It is possible to adjust it too tightly, so one or more of the balls will bind and result in pitting of the ball, cone, cup or all three members. It is important that the adjustment of this bearing be understood by the car user if he is to get the durability of which the bearing is capable.

COST.

To arrive at the approximate cost of a cup and cone bearing, we will assume that the manufacturer wishes to purchase the parts outside his factory. Pressed steel cups, grooved for the retainer, hardened and polished, of the sizes mentioned above, may be bought in quantity for 10 to 25 cents each, depending on the size, the tool cost varying from \$30 to \$50.

The cones may be made on automatic machines, hardened, ground and polished for 20 to 35 cents each.

The retainers cost 2 cents, with a tool cost of \$10.

The approximate price of steel balls is as follows:

									Dollar
3-16	diameter							٠.	.0010
1-4	"								.0013
5-16	"							٠.	.0025
3-8	"								.0037
7-16	"								.0080
1-2	"								.0100
9-16	**								.0135
5-8	**								.0150
11-16	"								.0185
3-4	"								.0250
7-8	"		•	•	•			٠.	.0450

If we assume a certain average size of bearing, as, for instance, the front hub inner bearing shown in Table II, we can gain some idea of the total cost: A fair cost of this bearing in quantities of, say, 1,000 is as follows:

Cup	\$0.18
Cone	. 20
Retainer	. 02
Twelve 5-8 inch balls	. 18
Total	\$0.58

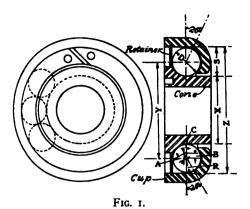

This figure, of course, represents the cheapest cup and cone bearing, but is representative of many of those used. With a better grade of material in the cone and balls the cost would be a little more, perhaps 75 cents for the whole bearing.

Without accurate data as to the relative efficiency of the bearings mentioned herein, it would be unfair to make a comparison of the costs of the different bearing equip-

ments. The intention of the above is rather to give some idea of the possibilities of the cup and cone bearing where the cost of the bearing equipment must be kept at a minimum.

#### The Care of Steering Joints.

The four joints of the steering are apt to be very much neglected. By the four we mean the two ball joints of the steering rod and the two plain joints of the cross coupling rod. Although leather cases are so easily made and so cheaply procurable, many cars are going about with these four joints exposed to mud and dust. There is no better grinding material than road grit and oil or grease, and consequently these four unfortunate joints, which are among the most important on a car, are being rapidly worn away. On the other hand, some users seem to think that if they put leather covers over the joints they can practically neglect them for twelve months so long as they have packed them full of grease before putting on the leather covers. This is a mistake unless outside means of lubrication are provided, and even then it is advisable to remove the covers and to examine the joints occasionally. Some steering joints have little grease cups or small oil lubricators, which project through the leather casing, so that lubricant can be added from time to time; but many good cars are turned out without anything of the sort. The joint is simply smothered in grease, and then the leather case is strapped on. This does very well for a time, but at least four times r year the covers should be removed, the joints thoroughly cleaned with paraffin, and then they should be carefully and copiously oiled begore being repacked with grease. While doing this they should be most carefully examined to see that all nuts and pins are absolutely safe and sound, and that no undue wear has taken place. Of course, the ball joints can be adjusted, but the two plain joints of the coupling rod are non-adjustable, and if much worn it is necessary to fit new pins or to rebush the coupling rod.—The Auto-

In Yarmouth, Nova Scotia, a city of 6,000 inhabitants, thirty-six automobiles are owned.

# Maintenance and Repairs

#### Some Hints on the Care of Tires.

The cost of pneumatic tires, for repairs and renewal, constitutes in every case one of the most important items among the running expenses of an automobile, so that the owner bent on economizing in the upkeep of his car may well start by endeavoring to save his tires as much as possible. The tire item has gained still further in importance of late through the repeated rises in the prices of tires. The rapid wear of the tires is conditioned by the great weight they are called upon to sustain, the rough roads the cars are driven over and the high speed at which they are frequently driven, and in such hard service the tires cannot well be expected to be long lived, but there are many little kinks and expedients that are not known to the average novice driver which permit of materially lengthening the life of the tires.

#### LARGE TIRES MOST ECONOMICAL.

In order that the tires may wear well and not be a source of continual trouble, it is of the first importance that they be of liberal size in proportion to the weight of the car and its load. Often, if the tires suffer continually from punctures and bursts, instead of condemning the make of tire forthwith the user will do well to see whether they are not overloaded. Although a general table of permissible weights applicable to all makes of tires might be given, it is better to base this investigation on a table of permissible loads issued by the particular manufacturer, for the reason that the different makes of tires differ somewhat in respect to strength of walls and other particulars, and therefore in respect to carrying capacity. If it is found that the car manufacturer has stinted the tire equipment, it will be advantageous, after the first set of tires has worn out, to use a size larger tires all around. This is facilitated by a recent move on the part of several tire manufacturers, who have brought out tires of such shape as to fit the rim for the next size smaller standard tire. Thus 31/2 inch tires may be placed on 3 inch rims and 4 inch tires on 31/2 inch rims without any extra expense besides the cost of the tires. The advantage of using large tires in proportion to the load to be carried is now generally recognized and has received a striking recognition by the recent adoption of very large tires on the cabs of the principal New York taxical companies.

#### PROPER INFLATION.

If the tires are of the proper size, the next thing to look out for is that they are kept properly inflated. Running with a partially deflated tire is the cause of destruction of a great many pneumatic tires.

If the air pressure in the tires falls below a certain point, dependent upon the size of the tire and the load carried by it, the side walls of the tire are unduly bent and the fabric layers in these walls are subjected to extreme stresses which cause what is known as rim cutting. Pumping up a large tire by hand is quite an arduous task, and it is a fortunate thing that in all the public garages compressed air is now kept on tap, as it were, which enable the driver to inflate his tire without physical exertion. Many of the larger cars are now also equipped with air compressors, which form either a part of an automatic starting mechanism or are fitted specially for the inflation of tires.

The tires should always be inflated by gauge to the pressure recommended in the tire maker's catalogue for that particular size, and it is important that the pressure gauge or manometer be connected directly to the valve stem, and not to the pump, as otherwise the resistance of the valve to the passage of the air will affect the reading and cause the gauge to give incorrect indications.

#### JACK CAR UP WHEN IDLE.

When a car is not being used for an appreciable length of time, it should always be jacked up or propped up, so as to take all of the load off the tires. If the load remained on the tires, the latter would lose their pressure in the course of time, and the fabric in the side walls at the point of the tire nearest the ground would then be unduly strained and likely be permanently injured. If the car is to be laid up for many months, it is the best plan to remove the tires entirely and to wrap up the outer covers and inner tubes separately and store them in a dark room not exposed to extreme temperature changes. If the tires are thus removed, it is advisable to carefully examine the bead portions for any traces of rust, which should immediately be thoroughly cleaned off, and the rims should also be thoroughly cleaned of rust and given a coat of air-dry enamel to protect them against rust during the period of non-use Before the outer covers are stored away they should be allowed to dry in the open air for a day or so, to permit the moisture which may have entered any cuts in the tread to escape.

#### TREATMENT OF CUTS.

To prolong the life of outer covers they must be closely watched for cuts and tears developing in the tread portion. If the cut does not extend entirely through the rubber portion of the tread, it may be filled with tire cement and then vulcanized with a home vulcanizer of either the steam or electric variety. If the cut extends entirely through the outer rubber layer to the fabric, it is a very serious matter, for then the moisture of the road will get into the fabric and rot it in short order. It is a somewhat peculiar fact that, whereas moisture lengthens the life of rubber, it affects the fabric very prejudicially. In the case

of deep cuts extending entirely through the outer rubber protector, if the tires are continued in use sand and dirt will usually work through the cut and in between the separate layers of fabric, thus causing what is known as a blister or swell. This considerably reduces the resistance of the tire at that point to sudden shock and pressure, and after a tire has been damaged in this way it is usually of very limited serviceability. When deep cuts are suffered which the owner cannot repair himself, it is advisable to immediately send the tire to the factory and have it repaired there, if it is still in condition to be repaired.

#### UNDUE WEAR OF FRONT TIRES.

It has often been observed that the front tires on a car wear even faster than the rear tires, in spite of the fact that the rear ones have to carry by far the largest weight, and in addition have to support the strains due to driving and braking. If this trouble is experienced, an examination will very likely show that the front wheels are out of alignment. This disalignment may be due to a considerable number of causes which were recently investigated by one of our French contemporaries. Some of these causes are as follows:

Steering tie rod improperly adjusted. Steering knuckle arms bent. Wear in front wheel bearings. Wear in steering knuckle pivot. Looseness in steering joints.

The effect of want of alignment between the two front wheels was discussed at considerable length in our "Communications" columns about a half year ago, and a number of experts who discussed the question in special articles arrived at the conclusion that the wheels should be set so as to be perfectly parallel, and should neither be "toed in" nor canted. When the wheels are not perfectly parallel there is a continued grinding effect, the results of which are plainly perceptible on the tread.

#### DON'T TWIST WHEELS ON FLOOR.

Wherever it is possible the car should be started with the front wheels in the straight ahead position, and the wheels only moved over to one side or the other after the car is in motion, as the wrenching around of the wheels on the ground when the car is stationary is quite injurious to the tires. In city driving where frequent stops are made alongside of the curb, care should be taken not to drive too close to the curbstone, so the tires will not rub up against it, which is quite injurious to the side walls. Running in car tracks is also to be disapproved of.

#### FIERCE CLUTCH AND BRAKE ACTION.

Under ordinary conditions the rear wheels naturally wear much faster than the front wheels, for the reasons already pointed out. Careless driving will further shorten the life of the rear tires, especially when it is exemplified by letting the clutch in suddenly and jamming on the brakes. The strains of any sudden variations in

the motion of the car, either increases or retardations of the speed, must be borne by the driving wheel tires, and naturally affect their life very seriously. If it is found that the clutch action is "fierce," the clutch should be given a treatment with castor oil or some other lubricant which will make it take hold more gradually while not preventing its holding when engaged at full pressure. The brakes should always be applied as gradually as possible, unless a quick stop is imperative; in fact, the brakes should be used as sparingly as possible, and the car always be allowed to come to a stop of its own account, as far as possible.

#### VULCANIZE PATCHES.

When patching inner tubes it is advisable to vulcanize the patches, especially on fast cars which are used for long trips during the hot season, as the heat engendered by the friction between the inner tube and the cover, and between the separate elements of the cover, tends to loosen the patches if they are not vulcanized. There are now a number of simple and inexpensive vulcanizers for inner tubes on the market, and every garage should be equipped with one. Where the patches are not vulcanized, however, care should be taken not to start out with patched tubes on a long tour, as the patches are likely to come loose when the car is being driven continuously at speed, and give considerable trouble. It is better to start out with new tubes and to use up the old ones in winter time in city and suburban driving. To reduce the friction between the cover and the inner tube, the inner surface of the cover should be strewn with talc before the tube is introduced. This also tends to prevent pinching of the inner tube, which is a frequent cause of injuries to it. It has recently been proposed to use flake graphite to lubricate the inner surface of the cover, but we have not yet heard regarding experiments with this material for this purpose.

Oil, kerosene, etc., are enemies of rubber and it is dangerous to stand a car on a greasy floor.

### Emergency and Roadside Repairs—II.

By H. H. Brown.

One way in which the roadside repair differs from a repair made in the shop is that, as a general thing, it is made only in order to get the car home or to a place where a more permanent repair can be made.

Take, for instance, the case of a four cylinder motor in which one of the exhaust valves is broken. While the motor will not run with its accustomed smoothness, yet it will run, and it is a matter for the owner's or driver's judgment, whether under the circumstances it is desirable to do anything more than remove the broken valve from the cylinder in order to avoid further trouble. However, in the case of a broken inlet valve the situation is quite different.

as under these circumstances the carburation of all the cylinders is likely to be affected. Fortunately, however, this trouble is comparatively rare.

If a spare happens to be carried it, of course, can be fitted in place. If there is no spare and the exhaust valve is a duplicate of the inlet valve, as it now generally is, then the exhaust valve can be shifted to the inlet valve position and used as such in order to prevent interference with the carburation from the open inlet port. If this cannot be done the inlet port to that particular cylinder should be plugged in some manner, the exhaust valve removed and the ignition cut off from that cylinder. This is preferably done by grounding the secondary lead to that cylinder in case a magneto is used. In the case of a multiple coil system the vibrator for the coil may be put out of action by slacking off the adjusting screw or simply placing a bit of cardboard or paper between the points. In the case of a broken exhaust valve it might be as well to put the inlet valve out of action, if this can easily be done.

It is a good idea to carry at least one extra spark plug, which is known to be in good order, and to see that it is carried in such a manner that it will remain in the aforesaid condition. However, with a four cylinder motor this is not absolutely essential, although at the first opportunity a plug which is broken down should be replaced.

Right here it may be as well to speak of a habit which is comparatively common among operators, especially among owners who care for and drive their own cars, and that is the habit of carrying "deadwood" in the repair kit. The most common example of this is the carrying of broken plugs, and probably next in order come punctured or blown out inner tubes. Only one instance has ever come to the writer's attention in which a broken plug might have been of use. In this instance a four cylinder car was fitted with two complete sets of ignition, an individual coil and a magneto system. One of the plugs of one cylinder "went bad." This was on the battery side. As the battery was only used for convenience in starting this did not bother much. However, the plug was rather a poor specimen, and eventually the central electrode was blown bodily out of the porcelain by the force of the explosions. This left a hole about an eighth of an inch in diameter through which gas and air were free to pass, The noise made under these conditions was of such a quality and volume as to make the owner of any of the modern exhaust blow whistles green with envy. Fortunately, a garage where a new plug could be obtained was comparatively close at hand. Even in this instance, had the garage not been handy, some remedy probably could have been devised.

Perhaps, however, there is considerably more excuse for carrying round an old inner tube than a broken spark plug. The uses to which it may be put are legion. For instance, it may be used for washers at va-

rious points to reinforce inner tubes where there is a small blow-out in a shoe, and even on occasion as a rubber water pipe connection where the regular hose has sprung a bad leak, although in this case a portion of it could probably be used to much better advantage to stop the leak with the aid of some string or wire.

A most interesting example of how old inner tubes may be used was brought to light in the case of an experienced driver. who was unfortunate enough to have four punctures or blow-outs in one day. Thus all of his spare tubes were exhausted. It was apparently a case of waiting or riding home on the rim. However, the following expedient was tried with good success: The valves were removed from two of the punctured tubes, and these tubes were placed with the third inside the outer casing. The other edge was then put in place, which was not accomplished without some difficulty, and the security bolts were screwed down tight. The result was that the car was driven home quite a distance, and no damage resulted to the tire from rim cutting. However, the exceptions prove the rule. If one is determined to carry punctured inner tubes they should be so marked as to be unmistakable, as it is rather provoking after placing a tube in a shoe to find that the one just put in place is no better than that which was removed.

### Contract for Michigan License Plates.

The Burdick Enameled Sign Company, of Chicago, will probably get the contract for the automobile number plates to be issued in Michigan the coming year. An order for at least 30,000 of these plates will be given, as two plates are required on each car, and there are now more than 12,000 cars in the State. The license fee in Michigan is \$3 and the number plates are furnished applicants free of charge. The plates will have a white background and have the number stenciled on them in black, together with the word "Michigan" and the State seal. The new number plates will be issued the first of the year, when all licenses must be renewed.

#### Foreign Market for Taxicabs.

An American consular officer in the Far East reports that there is an excellent opening for the introduction of taxicabs in a large city in his district. The operators of such a style of vehicle would be exempt from the existing carriage regulations, and, owing to the inadequacy of the present cab system, a large profit should be realized. Additional information can be obtained from the Bureau of Manufactures, Washington, D. C., by referring to No. 3,959.

L. L. Heller, president of the Sterling Motor Car Company, of Binghamton, N. Y., was instantly killed near Waverly, N. Y., on October 6, when his car was struck by a Lehigh Valley train at a crossing and completely wrecked.

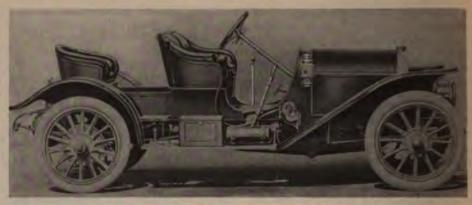

# NEW VEHICLES AND PARTS

#### Stoddard-Dayton Models for 1910.

The new models of Stoddard-Dayton cars, manufactured by the Dayton Motor Car Company, of Dayton, Ohio, differ from the previous models chiefly in the refinement of details. Three distinct sizes of power plant, mounted in some seven different chassis, are again offered for the coming season; all models show a slight increase in wheel base and general capacity, together with a slightly higher horse power rating. The 30 horse power chassis is now offered with 108 inch wheel base; the 40 horse power with 116 inch wheel base for both roadster and touring car, and the 50 horse power with 120 inch for the roadster model and with 128 inch for the touring car. The 30 and 40 horse power touring cars are five passenger cars, while the 50 horse power is of seven passenger capacity, carrying rather unique folding auxiliary seats. which have been furnished for the past two seasons. The roadster models carry a large variety of bodies, including single and double rumble, artillery seats and two different types of miniature ton-

A 30 horse power chassis especially designed for closed town cars has been added to the line. This chassis is of 108 inch wheel base and will carry three types of closed bodies, viz., limousine, landaulet and a town car with short peak. Inside driven coupé and large limousine or landaulet bodies are also furnished with the other chassis, thus making quite a large line of closed cars.

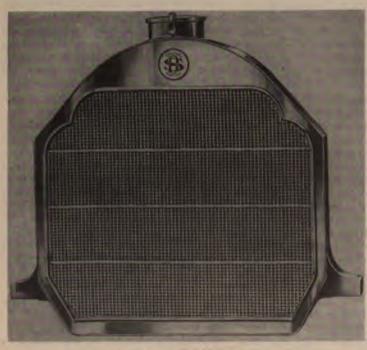

STODDARD-DAYTON 10C 40 HORSE POWER ROADSTER.

Among the constructional changes may be mentioned the adoption of the cellular type of radiator, three-quarter elliptic rear springs, the placing of the gasoline tank in curved brackets symmetrical with the upper part of the three-quarter elliptic spring at the rear of the car, and cutunder bodies on all touring and closed cars, with an artistic and original fender design, which continues the contour of the wheel house through to the tip of the fender, with just a slight upward flare at the end. The French type of rear wheel has also been adopted, in which every other spoke is bolted to the brake drum, which is of very large proportions.

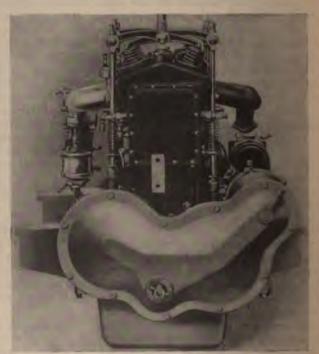

The changes made in the motor on the 40 and 50 horse power cars are hardly noticeable. The same general cylinder design with spherical combustion chamber is employed, but the valve operation has been changed in that two cam shafts are now employed with double push rods, which permits of overlapping of the valve opening periods. Practically the same sort of walking beams are employed as formerly with the single cam shaft and push rod, both walking beams being carried on a single yoke, and offset in such a manner as to avoid the staggering of the valves.

A slight change has also been made in the exhaust valve cage, which is now held in place by a double yoke, which is given a slight tension on a stud midway between Nos. 1 and 2 and 3 and 4 exhaust valves. The exhaust and intake sides of the motor have been reversed from last year, which makes for a better distribution of the accessories, including the pump, magneto and carburetor. The two sets of spark plugs are now located upon opposite sides of the motor. This permits of a simple and neat arrangement of the wiring. The usual battery ignition coil has been removed from the dash and is now housed under the hood, thus leaving the dash perfectly clean, with the exception of the switch, oil and gasoline gauges.

The principle of interior motor lubrication has been retained, but a rotary

NEW CELLULAR RADIATOR.

FRONT VIEW OF MOTOR.

pump is now used instead of the former plunger pump.

All models for the coming season will have double ignition-by magneto and battery. On the 50 horse power models, known as F and K, this system comprises a Bosch magneto and the Delco system, this latter consisting essentially of an especially designed non-vibrating four coil induction unit, a master circuit breaker and kick switch of new construction; coil and circuit breaker are enclosed in a heat and oil proof steel jacket which permits of the same being placed under the hood. On the 30 and 40 horse power models (A, C, H and B) the Splitdorf dual system will be employed, the induction coil for the battery system being carried on the side frame member under the dash, the same as in the other models.

The change gear and the gear shift levers remain in the same location. A new universal joint is located between the change gear and the drive shaft, which eliminates the leather boot previously used, and is designed for the retention of grease, with which it is packed.

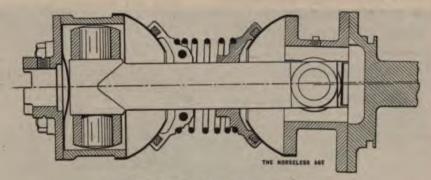

A simple brake equalizer has been devised, and the braking surface has been greatly increased by increasing both the diameter and the width of face of the drums. All models have both a foot and an emergency brake, these being of the usual expanding and contracting design. The foot brake, which is the outside or contracting band, is now supported by a spring operated release, which eliminates any possibility of drag-

ging when not employed.

Every part requiring lubrication is provided with a grease cup, including the spring shackles, spring seats on the rear axle, radius rods, roller bearing at the front end of the propeller shaft, propeller shaft and torsion tube support, speed changing mechanism, steering gear, steering gear distance rods, starting crank and all parts of the motor that are not taken care of by the self contained oiler. The equipment of each car comprises a lubrication chart. All bodies on 1910 cars will be constructed of reinforced aluminum, and a very liberal option as to finish and upholstery is offered.

#### Novel Storm Protector.

G. C. Hanch, treasurer of the Nordyke & Marmon Company, Indianapolis, has invented a novel arrangement of inside curtains. Instead of having, as usual, several side pieces, Mr. Hanch uses but one piece for each side. In place of the ordinary celluloid storm front he employs a standard wind shield, to which the two inside curtains are fastened. In case of a storm breaking when en route the top can be put up, the wind shield raised and the curtains attached without any of the party getting wet. A light metal tube is attached to the back of the front seats in which the

STODDARD-DAYTON NEW UNIVERSAL JOINT.

side curtains are carried, rather than folding them up and carrying them under the rear seat, as is customary. Rolling the curtains and carrying them in this tube prevents cracking.

The Frayer-Miller Trucks for 1910.

Having abandoned the manufacture of pleasure vehicles, the Oscar Lear Automobile Company, of Springfield, Ohio, are devoting their whole attention to the production of the Frayer-Miller trucks. They make 1, 2 and 3 ton trucks. The 3 ton, their leader, is a facsimile of the others, only larger in proportion, and only it will be described here. No radical changes are found in the 1910 product, simply minor refinements.

The principal changes are an increase in the bore of the cylinders which adds about 5 horse power; the adoption of the splash oiling system in the crank case, of a disc clutch, a three point suspension and a bumper or gasoline tank guard in front.

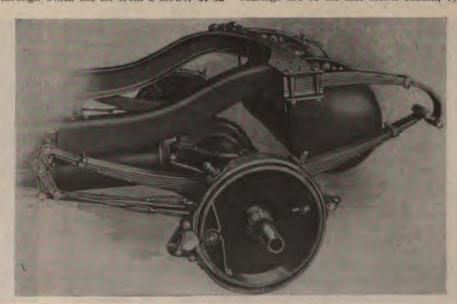

The cylinders, which are air cooled, are cast separately and covered with small bosses or projections to increase the cooling area and thereby aid in the cooling. The bore is 43% inches and the stroke 53%

The cylinders are covered with aluminum cases, which are part of the air shaft through which the air from a blower of 12

inches diameter and 4th inches depth passes, giving a positively conducted forced draught for cooling. The blower has sixtyfour corrugated blades, runs on annular ball bearings, and is driven by a Renold silent chain. The valves are both in a chamber above the cylinder, forming part of the cylinder head, and are contained in removable cages. They are easily accessible for grinding or inspecting. The valves have cast iron seats screwed and brazed to nickel steel stems, and are actuated by means of cam shafts on opposite sides of the motor. The valve lifters work on the valve stems through bell crank levers which increase the cam motion.

The pistons are 5 inches long, with flat heads, and have four eccentric compression rings with a 45 degree joint. They are ground on three sides. The piston pin is of nickel steel, fifteen-sixteenth inch in diameter and 41/4 inches long. The pin is hollow and held in place by two set screws. After the pin is in place a wire is put through the centre and through holes in the set screws that hold the pin in place, and in this manner the set screws are securely locked.

The piston pin bearing is of phosphor bronze, and the oil hole in the top is countersunk at a wide angle to catch oil from the splash. The lower connecting rod bearings are of die cast nickel babbitt, 15%

STODDARD-DAYTON 1910 REAR CONSTRUCTION.

FRAYER-MILLER TRUCK WITH OPEN DELIVERY BODY.

inches in diameter and 23/4 inches long. The connecting rods are drop forged of I section, with marine bearing caps held in place by two studs. The connecting rods and crank shaft are both made of 45 point carbon steel. The cam shafts are seveneighth inch in diameter, hardened and ground. The cams, which are also hardened and ground internally and externally, are keyed and pinned to the shaft. The bronze cam shaft gears mesh with a steel crank shaft pinion. The gears are housed in an oil tight compartment cast integral with the aluminum crank case. The crank shaft is drop forged, heat treated and ground, and has three main bearings. The diameter of all the bearings is 15% inches. The lengths are as follows: Front bearing, 3 inches; centre bearing, 3 inches; rear or flywheel end bearing, 4 inches.

The crank case is in two parts, the lower portion being independent of the crank shaft bearings. The upper portion is reinforced by I beam construction to avoid the possibility of getting out of alignment.

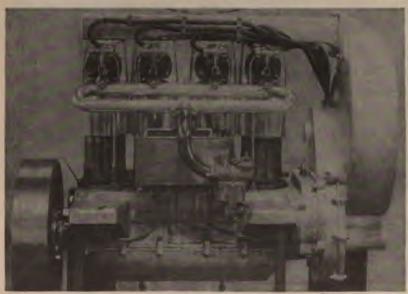

The mechanical oiler is located on the right side of the motor, directly beneath the inlet manifold. The inlet manifold is a complete ring, with the inlet chambers on one side and the carburetor in the centre on the other. A Breeze carburetor is used. The flywheel is of cast iron, of 1734 inches diameter and 334 inch face. The clutch is of the multiple disc type, plain steel plates working between steel plates covered with composition. It is claimed that this design does not require any oil. The releasing collar works through a ball thrust, and the clutch spring is also carried on a ball thrust. A universal joint between the clutch and transmission permits the easy removal of the clutch. A disc brake is attached to the direct drive shaft just back of this universal joint, and when the clutch is thrown out the same motion of the pedal applies this brake, stopping the gears so they can be changed quickly.

The change gear has four speeds forward and one reverse, and is of the selective type. The gear casing is an aluminum casting of elliptic cross section, with manganese bronze heads. The shafts, both of which are square, are hardened and ground and carried on annular ball bearings, and

the male end of the direct drive shaft is supported by an annular ball bearing in the end of the direct drive gear. The gear case is oil tight, having stuffing boxes at both ends of the direct drive shaft.

The propeller shaft has two universal joints of the block and trunnion type, and connects the change gear with the jack shaft. On the driving bevel pinion shaft is located the foot brake operating on a drum. In the centre of the jack shaft is located the differential, which is of the bevel pinion type, and runs on annular ball bearings. The jack shaft is supported at both ends by annular ball bearings. Whitney chains of 1¼ inch pitch, with three-quarter inch rollers and three-quarter inch wide, connect the rear wheel sprockets with the jack shaft sprockets.

The rear axle is a 2½ inch square har, with the wheels running in Timken roller bearings. The front axle is a 4 inch I section drop forging in a single piece, and has a 4 inch drop in the centre. The front wheels are carried on Timken roller bearings, and the pivot bolts have Timken roller bearings to ease the steering gear.

INLET SIDE

FRAVER-MILLER MOTOR

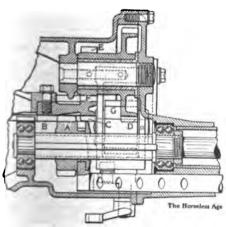

FRONT VIEW,

The wheels are all of the artillery type, 36 inches in diameter. The front wheels are shod with 4 inch solid rubber tires and the rear wheels with 31/2 inch dual solid tires. The main frame is of 6 inch channel steel and the sub-frame of 4 inch channel steel. The sub-frame is provided with a flexible bearing in front, which prevents binding of the motor and change gear shafts when traveling over a rough road with full load. A. L. A. M. standard threads and screws are used throughout, with castled nuts and bolts. The front springs are semielliptic, 40 inches long by 3 inches wide, with ten leaves. In the rear there is a three point platform spring, the side members of which are 40 inches long by 3 inches wide, with twelve leaves, while the cross member is 38 inches long by 3 inches wide, and has sixteen leaves.

A worm and nut steering gear, with a 20 inch wheel, makes the car steer quite easily with a load. The control levers for spark and throttle are underneath the steering wheel.

The motor is located directly under the driver's seat, with the change speed lever and emergency brake lever at the driver's right hand. There are two brakes, one expanding in the rear wheel drums and one contracting on the differential. The rear wheel brakes are the emergency brakes and are operated by a hand lever; the differential brake is the service or foot brake. The loading space back of the driver's seat is 12 feet long and 56 inches wide. The gasoline is carried in a flat tank in front of the dash, which holds 13 gallons. It has a reserve compartment, which will carry the car 10 miles after the first warning is given. The wheel base is 128 inches, the tread 66 inches, and the road clearance 111/2 inches. The Atwater Kent system of ignition is used.

The regular equipment comprises two side oil lamps, one oil tail lamp, a horn, a jack and a tool kit. Tools and batteries are carried in a watertight sheet steel box built into the running board. There is also a compartment between the seats in which small tools and an oil can may be kept.

TRANSMISSION PORTION OF PROBST TRANS-MISSION AXLE, TYPE B-2, SEMI-PROGRESSIVE.

#### Speedwell Changes for 1910.

Only changes of minor importance have been made in the Speedwell car manufactured by the Speedwell Motor Car Company, of Dayton, Ohio, for 1910. These changes have been made with the object of increasing the comfort of the occupants and of refining the mechanical details. They can be summed up in a few words.

The wheel base has been increased to 121 inches, the springs have been made wider, the wheels increased in diameter from 34 inches to 36 inches, and the body has been hung 3½ inches lower to the ground. The valves have been removed from the right to the left hand side of the motor, and the water pump and Bosch magneto are now placed on the right hand side. A dual ignition system is being fitted. The front axle has had much of the drop taken out of it, making it nearly straight, and thus giving greater road clearance. The space between the running board and the body is closed in, and the sod pan is hung by means of spring fastenings, which make it easy to remove.

The company will continue to make only one type of chassis, equipped with a four cylinder motor of 5 inch bore and stroke each. A considerable variety of bodies are offered, however, and some of the body designs are new, including the Torpedo roadster and the touring car bodies. The only part carried on the dash is the combined coil and switch of the dual ignition system.

The gasoline is stored in a square tank under the front seat, holding 18 gallons, except on the roadster, where an elliptic tank can be had back of the front seat holding 25 gallons. Thirty-six by 4 inch tires are provided on all models, except the seven passenger touring cars and the limousines, which are equipped with  $36\times4\frac{1}{2}$  inch tires.

All cars are equipped with two gas lamps, generator, two side oil lamps, one oil tail lamp, horn, jack, tool kit, tire repair kit, pump, battery box, tool box, robe rail, foot rest and Bosch magneto.

#### The Probst Transmission Axles.

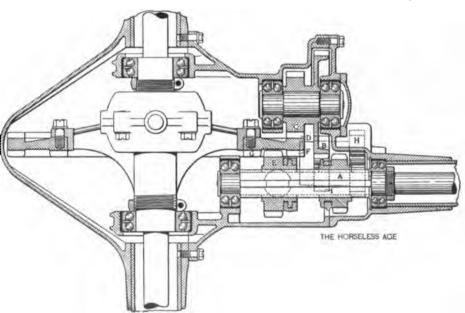

These change gears illustrate the fact that new methods of machining gears often bring neglected types into use. In this case the novel feature is the use of a series of crown gears in place of the usual bevel and spur reductions. These crown gears have all the generating lines of their teeth perpendicular to the axis of their shaft. The teeth are cut in a Fellows gear shaper, by means of an attachment which rotates the crown gear in a plane parallel to the travel of the cutter. They mesh with ordinary spur pinions, which are slid into mesh with different sizes of crown gears to get the various speeds. The 20 degree stub tooth is used throughout. It is claimed that a line contact is obtained.

The semi-progressive type, B-2, is for cars of from 10 to 16 horse power at 1,000 r. p. m. The gears are 7-9 pitch, with three-quarter inch face. The main shafts and axle shafts run on New Departure bearings.

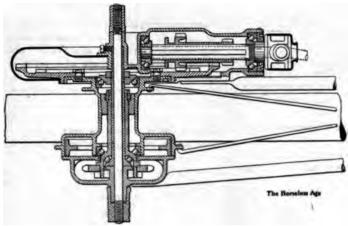

For the first speed power is transmitted through gears A, D, E, F. For the second speed gears A and C are in mesh; for the third speed gears A and B. Thus both high speeds are direct. To obtain the reverse, gear A is slid into the neutral position and pinion G is swung up to mesh with A and D. Power is then transmitted through gears A, G, D, E and F.

In the selective type of gear, D-3, New Departure bearings are used throughout. Second and third speeds are obtained by sliding pinion E, which meshes with F for the second and with G for the third speed. These and the back gears are 5-7 pitch. The other gears are 6-8 pitch. The faces are three-quarter and fifteen-sixteenth inch, respectively. The gear is recommended for cars of from 22-30 horse power at 1,000 r. p. m.

The first speed and the reverse are obtained by sliding pinion A. For the first speed power is transmitted through A, B, C

PROBST TRANSMISSION AXLE, TYPE D-3, SELECTIVE.

PROBST MOTORCYCLE GEAR SET, HORIZONTAL SECTION.

and D, and for the reverse through A, H, I, B, C and D.

A very simple gear, giving two speeds forward, with no reverse, is made for motorcycles.

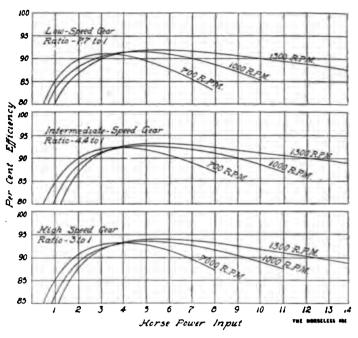

The automobile type of gear has been tested by the General Engineering Company, of Syracuse, with the results shown in the following curves. These show the crown gear to be efficient for moderate powers. It will be seen that the best efficiency on the low gear is only 1½ per cent. lower than that for the intermediate. As the torque increases the efficiency falls, so it is probable that these change gears will find their widest use on cars of moderate power. These gears are manufactured by the Seagrave Company, of Columbus, Ohio.

#### Two Warner Parts Companies.

T. W. Warner, who in June last sold out his interests in the Warner Gear Company, of Muncie, Ind., has since organized two separate companies for the manufacture of auto parts. The Warner Manufacturing Company, of Toledo, has the contracts for 1910 for the Overland transmission and steering gears. The Overland Company gave up one of their large buildings to the Warner Company for this purpose. Though both companies occupy the same building they are entirely independent of each other. The T. W. Warner Company, of Muncie, devote their whole attention to the production of cone clutches and steering gears, while the Warner Manufacturing Company at Toledo devote their time to transmissions alone and gears. It is intended to combine the two companies in the spring and build a large factory at either Detroit, Toledo or Muncie, Ind.

### New Packard Power Plant Addition in Service.

The Packard Motor Car Company, of Detroit, Mich., on last Friday night started their new 4,000 horse power steam engine, and celebrated the event by a dinner given in the engine room to about thirty executives of the Packard Company, the installing engineers and Packard engineers. The company's power plant now comprises

PROBST TRANSMISSION AXLE TESTS.

three engines developing together 6,000 horse power, and work on another addition to the plant has been started. The company is at present working with a night shift of 1,000 men, and when the new engine was started and the old one cut out the former had to take up at once the entire load of the factory.

### Simplex Motor Car Company Elects Officers.

The Simplex Motor Car Company, of Mishawaka, Ind., held its annual meeting on October 1 and elected the following officers for the ensuing year: T. C. Starrett (Detroit) president; R. E. Kamm, vice president; D. A. Shaw, treasurer, and E. G. Gulick, secretary and general manager. The company is at present building an addition to its plant, and is said to be in a flourishing condition.

### Order for Massachusetts Number Plates.

The Massachusetts State Highway Commission has awarded a contract for supplying 52,700 number plates. Under the new law automobiles are registered annually, and the number plates are to be changed each year. The design of the plate for 1910 will be the same as the present year, except that the color will be reversed. Next year the background will be of white enamel, and the letters and figures will be of blue. This year the figures are white with blue background. The registrations commence December 1, and the commission has made it a condition of the contract that at least 10,000 number plates must be delivered at that date. After that the contractor can supply 5,000 monthly until the whole number is furnished.

The order calls for 24,000 pairs of regular plates attached to the ordinary machine, two for each machine; also 475 sets of ten

plates each for dealers. These are to be numbered from 1 to 475, and in each case the figure is to be preceded by an "o." Ten plates are allowed each dealer. The third class number plates are those prepared for the diplomatic corps at Washington, who may be spending the season next summer in Massachusetts. There are about twenty of these plates.

#### Wisconsin Registrations.

Wisconsin's registrations will, without doubt, reach the 10,000 mark by January 1, 1910, according to present figures. On October 1, 9,423 automobiles had been granted licenses, or nearly 3.400 since January I. 1909. The registration law went into effect on August 15, 1905, and in the year following 3,853 cars were registered. December 31, 1908, showed 6,192 cars registered. Secretary of State Frear figures the total investment at more than \$12,500,000. Milwaukee's share in the registration is 3,850. About II per cent. of all automobiles so far registered are owned by farmers. A majority of cars are listed at from \$1,100 to \$1,400.

### Results of Kansas City Endurance Contest.

An endurance contest from Kansas City to Omaha, Neb., and back was conducted last week by the Kansas City Star. The contest was run in five days over a distance of 760 miles, and there were forty-nine contestants. The latter were divided into two classes—one for private owners and the other for dealers. In the owners' class D. E. Gudgell, who drove a Franklin runabout, was the winner, he being penalized only two points for adjustments to minor parts. The dealers' class was won by R. C. Greenlease in a Cadillac "30," which was penalized only one-tenth of a point on examination. The contest may be held annually in the future.

#### Two Cycle Engines.

Editor Horseless Age:

Will you kindly tell me, either directly or through your inquiry column, why the four cycle engine has been so generally used in automobiles, to the exclusion of the simpler two cycle engine?

What are the objections to the two cycle engine?

I make these inquiries because I am asked to interest myself in the manufacture of a car having a two cycle engine.

V. M. M.

One of the chief reasons why the four cycle motor is used for automobiles much more extensively than the two cycle motor is that the former was developed as a high speed motor much earlier than the latter. Some of the early American automobile builders attempted to use the two cycle marine motors then on the market, but found them to be much too heavy for the purpose. As Daimler, Panhard and others abroad had scored all their successes in the automobile line with four cycle motors, American inventors and engineers followed their lead and directed their efforts to the perfection of the four cycle motor.

One other reason why the two cycle motor has not been taken up more generally is that its experimental development offers considerably more difficulty than that of a four cycle motor. In all gasoline motors very much depends upon the sizes and the timing of the valves or ports. In a four cycle motor, if you do not hit it right the first time, you can change the lift of the valves or vary their timing as much as desired by simply making a new cam shaft. In a two cycle motor, however, you must discard the whole cylinder and alter your pattern so as to change the port location, which is, of course, much more expensive. Then, again, it is much more difficult to proportionately enlarge a two cycle cylinder than a four cycle cylinder. That is to say, if you have once developed a good four cylinder motor of, say, 4 inch bore and 5 inch stroke, it is easy to figure from it the proper valve diameter, valve lift, etc., of a motor of different cylinder dimensions. But it is by no means so easy to determine the proper port dimensions of a two cycle motor from the dimensions of the same kind of motor of different size. In fact we know of instances where companies with extensive experience with high speed, two cycle motors of one size "fell down" when they tried to develop a motor of different cylinder dimensions.

The only disadvantage of the two cycle motor in comparison with the four cycle

is that it consumes slightly more fuel per horse power hour. The difference has been set down at about 10 per cent. by some writers. Another thing that may be pointed out in this connection, although whether it may be considered a disadvantage depends upon circumstances, is that the two cycle motor lends itself less to air cooling than the four cycle.

You do not ask about the advantages of the two cycle motor so we will not enumerate them.—En.]

### Denver's Novel Street Traffic Ordinance.

Editor Horseless Age:

The enactment of a law establishing the right of way for vehicles at street intersections is both new and important. Laws have been passed covering almost every situation or condition arising in vehicle traffic except where two or more vehicles meet at street intersections, and this situation seems to have been generally overlooked. Denver, Col., with one automobile to every eighty of its population, is the first city to realize the necessity for such a rule of the road, and has accordingly enacted an ordinance defining the rights of vehicles at street intersections.

Section 1703 of Ordinance No. 124, covering this point, reads as follows:

"It shall be the duty of every person driving any vehicle, when approaching any intersecting street, alley or public way, to halt or slow up and allow any other vehicle approaching along the intersecting street, on the right, to have the right of way."

In addition to the above mentioned excellent rule, this Ordinance No. 124 requires an overtaken vehicle to turn out to the right when signaled to do so by a vehicle approaching from behind. Also, in common with New York, Boston and Chicago, all slow moving vehicles must keep close to the right hand curb to allow room for the passage of faster moving vehicles on the left.

LEWIS SEARING.

[We would point out in this connection that Mr. Searing has been championing the above mentioned rule concerning the crossing of street intersections in our columns and elsewhere.—Ep.]

#### Vehicle Springs.

Editor Horseless Age:

In your issue of October 6 I note with much interest an article by Frederick Strickland on "Shock Absorbers." Although I do not agree with him in several details, yet in a general way his conclusions in several respects, especially as to the action and results of so called "shock absorbers," agree with my experience.

Regarding his conclusion that a car cannot be perfectly sprung (and I assume he means practically satisfactory) I must differ with him, as I have "sprung" two cars with much shorter springs than standard, and they practically accomplish the result which Mr. Strickland indicates is im-

possible. I enclose you a copy of a patent lately granted on such a spring suspension, which I have decided to designate the floating spring suspension. I expect in the near future to apply for a trademark for this designation, and also enclose you a name plate designed with this purpose in view.

Mr. Strickland also states "that if springs could be made with enough internal friction no shock absorbers would be required." I think I have again anticipated him as per enclosed patent for a "wire spring" which has many other advantages, as briefly explained in the history of the patent itself.

Chas. A. Lieb.

[Mr. Lieb encloses us copies of patents Nos. 922,169 and 933,997. The latter covers an arrangement of quarter elliptic springs extending from the vehicle body at an angle of about 45 degrees downward to the axle. This spring system has already been described in these columns. The other patent relates to a wire spring. The specification describes the principle of this spring substantially as follows:

"It is not generally known why leaf springs, so called, are employed in the construction of automobiles, to the exclusion of spiral springs. The principal reason is that as the vehicle, when moving rapidly, encounters obstructions in the roadbed, the wheels and the chassis or body move differently. The former, being light, under the impulse of the springs take immediate cognizance of any irregularity in the road, whereas the body or chassis, having greater inertia, maintains its former position more continuously until the action of the springs under the influence of the inequalities in the roadbed induces a vibrating or oscillating action between the parts involved, which in the event of a succession of irregularities in the roadbed generates so much movement as to tend to rupture some parts of the structure, and also to unseat the passengers. In order, therefore, to control such continued vibration or oscillation, the leaf springs are preferred to spiral springs, because of the friction between the several leaves of the springs which acts as a brake upon their action, having to a degree the same effect as shock absorbers on automobiles, their operation being the same as the friction generated between the leaves of the spring; that is to say they impede or rather render sluggish the resiliency of the metal, which would otherwise be so pronounced as to produce objectionable results, as stated above. For the above reasons leaf springs are the form most universally used. In making these springs it has been customary to roll bar steel into a flattened or ribbon-like form, which is then cut into proper lengths for the individual leaves of the springs, and then additionally rolled so as to reduce the thickness of the ends. This process of repeatedly rolling the metal changes its atomic structure, because the metal which is upon the edges of the leaves has necessarily to move more than the

metal constituting the central portions of the leaves. Consequently the atomic structure at the edges is different from that of the central portion, and this lack of uniformity endenders crystallization when the springs are in use, resulting ultimately in fracture, bending or other defects.

"My invention, therefore, consists in a new and useful method in which to construct the leaves of such springs whereby I preserve the desired frictional contact between the several leaves, and indeed increase the same, and at the same time avoid the objections resulting from repeated rolling of the metal.

Under the preferred form of my invention I make the leaves of the springs from a series of bars placed side by side, and in order that they may be rigidly held in position so that their ends shall not become displaced, I prefer to deflect them at their central portions, as illustrated, and I also use this same method at one end of the springs when my invention is employed in so called quarter elliptic springs. I also prefer to so roll the metal that there shall be interlocking surfaces between the several bars whereby the friction is increased in addition to the additional surface thus obtained because of the wedge shape of the contracting parts of adjacent leaves." —ED.]

#### Auto Statistics.

Editor Horseless Age:

I would like some statistics of the automobile industry, and presume you are able to furnish the following information better than anyone:

- I. The number and estimated value of machines now in use in the United States.
- 2. Number of new machines made this year, and estimated value.
- 3. Number and value of machines likely to be made next year.

The number and value of machines made in France, Germany, Great Britain and Italy this year, the estimates for next year, and the total number of machines in use in the countries named.

ROBERT FULLERTON.

[The number of cars in use in the United States at the present time is about 200,000. and their original cost averaged probably \$1,000, making an aggregate of \$200,000.-000. This year about 82,000 machines were built, and their value also averaged around \$1,000. It should be understood that no actual census of automobile production has been made, but the trade organizations keep records of the production of their own members, and make estimates of the production of the other makers, and the above figures are based on their results. As to the number of cars that will be built next year it is idle to speculate. The automobile industry is rapidly expanding at present, but this expansion may, of course, be checked at any time through unforeseen contingencies. same applies to the production of the different foreign countries for next year. The production of cars in foreign countries the past year was about as follows: France, 25,000; England, 20,000; Germany, 7,000; Italy, 5,000. There are at present in use in England about 100,000; France, 44,700; Germany, 20,000; Italy, 10,000.—ED.]

### Magneto Ignition Matters. Editor Horseless Age:

On page 361, of No. 14, Volume 24, you make a statement to the effect that "very few magnetos are so adjusted as to run their cars on the high gear at a sufficiently low speed to make driving safe in crowded traffic or over very rough level roads. The battery systems of such cars usually provide a very much lower minimum speed. In order to drive on the magneto under such conditions, the clutch requires to be almost constantly slipped, and there is thus a good deal of unnecessary wear and tear thereon. An operator will often resort to clutch slipping, and even change to a lower gear, rather than reach down to the dash and change from magneto to the battery and coil system."

We think it very strange that such a broad statement should be published at this stage of the development of the magneto. You are surely aware that one of the first requirements of a high grade magneto is that it fulfills exactly the conditions which, according to your article, it does not fulfill. If the situation was really as your article would indicate, it is quite evident that the magneto is not the success which popular opinion and experience would indicate. No doubt there are many magnetos which act as Mr. Clough states. On the other hand it is not at all fair to the better grade of magnetos that such a statement should go unchallenged.

We are importers of high tension magnetos, and owing to our extensive experience with magnetos know pretty well of what we speak, and when we say that a high tension magneto can be installed on a modern car to run it at the very lowest speed of which the engine is capable of turning over, we think such a statement should carry weight.

When calling on the factories as a salesman it is the writer's business to install magnetos on test cars, which are then subjected to every possible form of abuse which a car or magneto would experience in actual service. Needless to say, driving on the high gear at a very low speed, not only on the level but up grade, is one of the first tests which a magneto receives. The writer can recall distinctly many occasions when such tests were made at different factories, and in every case the magneto fulfilled the particular conditions referred to perfectly.

Assuming such to be the case, it is hardly likely that the automobile manufacturer would deliver his car with the magneto improperly timed, so as not to fulfill these conditions. We are inclined to think that your contributor's experience was confined to magnetos of a lower grade, and in jus-

tice to instruments of high quality we protest against the automobile public receiving the impression that magneto ignition is unsatisfactory for city work.

Naturally such a statement appearing in your columns carries considerable weight, and we have already had occasion to discuss this matter with several individuals, who noticed the article now referred to, and who, not having personal experience in the matter, are naturally inclined to believe what they read in your columns.

We also take occasion to disagree with a statement on page 378 of the same issue, wherein you say: "Those who are familiar with high tension magnetos know that in these magnetos the current is produced in the secondary winding on the armature by short circuiting the primary winding, and thus decreasing the lines of magnetic force passing through the secondary coil."

The facts are quite to the contrary, it being well known that when the circuit of the primary winding is quickly opened or broken, the high tension current is produced, the primary winding being normally short circuited. Furthermore, in the comparison being made between high tension magneto and the apparatus being described, the action of the rotating primary and secondary windings in producing the arc flame is not referred to, which is hardly a fair comparison.

We trust that you will take these criticisms in the spirit in which they are intended, but we believe that as the automobile public knows all too little about magnetos and magneto ignition, too much care cannot be exercised in having the public get correct information.

#### J. S. Bretz Company. Geo. W. Wacker.

[The magneto handled by our correspondents, and to which reference is evidently had, is provided with a special spring mechanism by which the strength of the spark is rendered independent of the motor speed below a certain point. This is the only magneto we know of that has such a provision, and it is therefore in a class by itself in this respect.—ED.]

At a recent meeting of the A. C. of France the secretary was instructed to canvass the manufacturers for entries for the Grand Prix race in 1910. If a sufficient number of entries are pledged the race will be held again, and it has been decided that there will be no limitation on the construction of the cars.

The taxicab drivers of Brussels, Belgium, went on strike on September 1, owing to disagreement over wages and also because the company attempted to hold them responsible for damages to the vehicles alleged to be due to faults of the drivers. The strikers, who number about 150, held several meetings and sent a delegation to the company in order to reach an agreement. The latter, however, were not willing to enter into negotiations.

#### Commercial Applications.

#### Commercial Notes.

A 40 horse power American automobile truck has been placed in service by the Joannes Company, wholesalers, at Green Bay, Wis.

A new automobile service for a passenger line was started in Madagascar, between Tananarive and Maevatanana, a distance of 215 miles.

The Houston Light and Power Company, recognizing the necessity of getting a repair man quickly to a scene of trouble, have purchased two motorcycles for their troublemen.

The Horace Wood Transfer Company, 45 Monument place, Indianapolis, Ind., have ordered two Marmon five passenger limousines, to be used in connection with their present horse livery.

The water department of the city of Milwaukee, Wis., will be supplied with an automobile costing \$2,500 if the recommendation of the committee on water works is adopted by the council.

Forsythe Brothers, of Washington, Pa., have established an automobile service between Washington and Brownsville, with one 40 horse power Grabowsky car. The firm does business under the style of the Washington and Brownsville Auto Passenger Transit Company.

Louis G. Deschler, an Indianapolis wholesale cigar dealer, has just placed his third motor delivery wagon in service, now doing all of his city delivery work with such vehicles. Hamilton & Harris and the House of Crane, also wholesale cigar dealers, also do all of their city delivery with automobiles.

A 1910 Mitchell roadster has been presented to the chief of the Racine, Wis., fire department by Capt. William Mitchell Lewis, president of the Mitchell Motor Car Company. Mayor A. J. Horlick, of Racine, several months ago made the gift of a 1909 Mitchell roadster to the city for use of the chief of police on condition that the council purchase a similar machine for the fire marshal.

Automobiles, which have always played a prominent part in municipal campaigns of Indianapolis, are cutting very little figure in the present campaign. One reason is that the majority of the candidates are men who cannot afford automobiles. Only one of the four candidates for mayor has an automobile in the present campaign, and only one or two candidates for the council have such vehicles.

The Indianapolis board of health has purchased an automobile equipped with a detachable tonneau for the use of its dairy inspectors who travel over the State inspecting all dairies supplying milk to Indianapolis consumers. Heretofore the inspectors have used horse drawn vehicles

and electric interurban lines, and they expect to accomplish twice as much work in a day as with their former transportation facilities.

A regular automobile service has been established between Fredericktown, Md., and Washington, D. C., the route leading through Brownsville, Centerville, Beallsville, Scenery Hill, Glyde and Pancake. The distance is 30 miles, four-fifths of which lies over the old national highway. Two round trips will be made per day with a 45 horse power, twelve passenger car of the closed type, heated and electrically lighted.

#### The National Highway from New York to Atlanta.

After a thorough inspection of the various routes between New York and Atlanta, the route for the "National Highway" between the two cities has been definitely selected. Starting on the 25th of this month the first public tour between North and South will be held over this route. More than twenty entries have already been received, and the event will be one of the most important of the season. During the summer a 30 horse power White steamer made three trips between New York and Atlanta, over as many different routes, and with the aid of the data thus obtained the official route has just been marked out by two White cars. A White steamer started from New York on September 23, and reached Atlanta on September 30. A White gasoline car started northward from Atlanta, and the two machines met at Martinsville, Va., and from that point proceeded southward together.

The route of the New York-Atlanta national highway leads across Staten Island, thence to Trenton, crosses the Delaware River at that point, and thence proceeds to Philadelphia. From Philadelphia the route leads almost due westward to Gettysburg, via Lancaster and York. At Gettysburg the route turns southward to Hagerstown, thence to Shepherdstown, W. Va., and from there to Winchester. From this point the route follows the famous Shenandoah Valley Pike to Staunton. From Staunton the route proceeds southward via National Bridge to Roanoke. South of Roanoke is a stretch of about 50 miles across the mountains where the worst roads of the entire route are encountered. As soon as the highway enters North Carolina better conditions are found, and there are good roads almost all the way across the State, via Winston-Salem, Greensboro and Charlotte. Greenville and Anderson are the principal towns in South Carolina through which the route passes, and entering Georgia the route proceeds via Royston, Winder and Lawrenceville to Atlanta, the total distance from New York being 1,050 miles.

#### Representatives of the Mitchell Car in California.

James W. Gilson, sales manager of the Mitchell Motor Car Company, of Racine, Wis., recently visited the Pacific Coast, and appointed the Osen & Hunter Automobile Company the northern California representatives of the Mitchell car, agents for the whole Pacific Coast, including California, Oregon, Washington and Idaho. A. E. Hunter becomes the general Pacific Coast superintendent, the Northwestern territory being under the direct control of George E. Johnson, now Pacific Coast manager of the Fisk Rubber Company.

Johnson's headquarters will be at Seattle, Wash. Hunter was originally established in San José, Cal., but went to San Francisco in 1907, and started an auto business there.

ROUTE OF NEW YORK-ATLANTA HIGHWAY.

### Claiming Damages for Injury from Road Obstructions.

Another claim for damages as the result of obstructions on highways has been filed under the new Wisconsin law making it a felony for a person to place obstructions on the road, and requiring highway superintendents to remove them on notice. Mrs. Margaret Christianson, of Manitowoc, Wis., struck an obstruction on one of the main streets of Manitowoc, and filed claim for \$1,000 personal damages, and \$1,505 damages to her automobile. Unless the claim is paid she has the privilege of bringing suit against the municipality. The first suit under this law is that by James T. Drought. of Milwaukee, who is secretary of the Wisconsin State A. A., as a private owner, for damages to his car while passing through Winnebago County, Wis. The outcome of these cases is being watched with great interest by owners, and since the claims were filed there has been a noticeable decrease in obstructions.

### Suit to Get Possession of Speedway Trophy.

The Jackson Automobile Company has filed suit in the county courts at Indianapolis to mandate the Indianapolis Motor Speedway Company to deliver to it the Wheeler & Schebler trophy. This was to have been the prize in a 300 mile race in the events at the speedway in August. Because of numerous accidents the race was called off, with Lynch driving a Jackson leading and having covered 235 miles. The company filed suit some time ago to obtain possession of the cup and demanding \$100,000 damages.

#### Tire Thief Sentenced.

A sentence of six months in the House of Correction, with the alternative of a fine of \$100, was imposed on Orlando Snedecker, of Chicago, in the Municipal Court at Milwaukee, Wis., on conviction of the charge of stealing spare casings and tires from automobiles left on streets by owners. Snedecker paid the fine. He owns a small repair shop at Chicago, and shipped the stolen casings and tires to Chicago by a circuitous route to avoid suspicion. His arrest cleared up many mysterious losses.

### Chicago Ordinance Limiting Curb Standing Privileges.

The Chicago City Council has passed an ordinance which prohibits vehicles being left standing on the streets unattended for more than an hour within the Loop district. The new ordinance relates to both automobile and horse vehicles.

### Lamps Must Burn While Car Is at Rest.

In an opinion recently handed down by Attorney General Denman, of Ohio, manufacturers of electrical lighting apparatus for automobiles will have to provide storage batteries to furnish the current while the car is standing if they wish to make their invention a success. A certain manufacturer desired to know what the meaning of Section to of the Ohio automobile law was, and the matter was referred to Attorney General Denman. He held that the law provided that three white lights must be displayed whether the car was moving or standing while on a public highway. The manufacturer desired to furnish light by a current generated by the drive shaft of the car.

### Ohio Motorists Threatened With Increased Fees.

Representative Owen J. Evans, of Stark County, announces that he has prepared a bill to be introduced in the next session of the Ohio General Assembly, providing for a large increase in the fees paid for registering motor cars. He believes that the fees as provided at present are not sufficient, and his schedule will more than double the receipts of the State Automobile Department. Considerable opposition to the proposed law has appeared already.

### Bar Harbor Exclusion Act Sustained.

The Law Court, the highest court of appeal in Maine, handed down a decision on October 2 in the Bar Harbor automobile controversy, sustaining the constitutionality of the ordinance which prohibits the use of automobiles on the roads of that resort.

#### Legal Notes.

F. W. Miller, of Milwaukee, Wis., was fined \$50 and costs for using the automobile of A. J. Monday, of Milwaukee, an expert automobile painter and repair man, without the owner's permission. This was the second and heaviest fine imposed under the new Wisconsin law aimed at this evil.

The Toronto, Ont., city council is considering the plan of having the name and coat of arms of the city painted on all municipal automobiles. Some of the city officials who are making use of these cars, including City Engineer Rust, are strongly opposed to the proposal, but, according to a Toronto paper, there are good and sufficient reasons for it.

At the hearing on the new garage ordinance before the Buffalo, N. Y., city council, to which reference was made in our last week's issue, several property owners claimed that the erection of a garage in a certain residence district would depreciate the residential property there. The committee referred the ordinance to the corporation counsel, to be redrafted so as to provide

for a permit or license without fee, and to require the consent of abutting owners.

An effort is being made in the State of Washington to prevent road house owners from selling intoxicating drinks to chauffeurs. The county commissioners of Pierce County have been requested to make a ruling which will have this result, and fewer accidents and smaller repair bills are expected to result if favorable action is taken by the commissioners.

#### Protests in Munsey Tour.

Leo H. Shaab, of Baltimore, Md., has made a protest against the award of the sweepstakes prize in the Munsey reliability tour to the Elmore car. Another protest against the action of the technical committee has been made by the entrants of the Marmon car, which is claimed to have been in collision with the Elmore as the machines entered Washington. Shaab's protest is based partly on this accident, which is alleged to have been due to a defect in the brakes on the Elmore, and he further alleges that there was a perceptible dish in one of the front wheels, which the committee apparently overlooked.

#### Garage Fires.

Three cars were destroyed in a fire which occurred in the garage of the Automobile Exchange and Supply Company, 18 Sabin street, Providence, R. I., on October 1. The establishment is conducted by Charles H. Goodwin. The cause of the blaze is unknown.

A fire which broke out in the Montauk Garage, 910 Union street, Brooklyn, N. Y., on October 8, resulted in the destruction of over thirty automobiles. The fire is thought to have been caused by the accidental ignition of gasoline used in cleaning the cars. The garage is located adjacent to the headquarters of the Long Island A. C.

A fire broke out in a two story brick building in the rear of 1575 Beacon street, Brookline, Mass., on October 5, which entirely destroyed the building and its contents, including a \$4,200 car. The building was occupied as a garage by James S. Murphy, and the fire is said to have been caused by the light of a gas stove igniting gasoline fumes. The accident illustrates the danger involved in any attempt to heat a garage by means of ordinary stoyes.

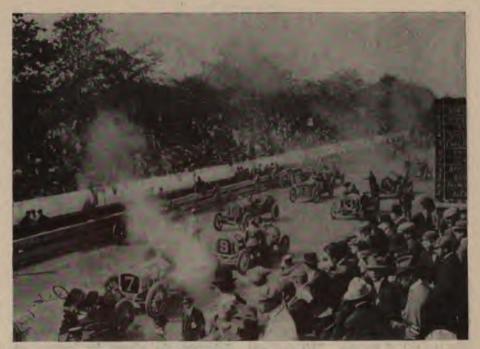

Five automobiles, valued at \$5.00, and other property to the amount of \$6.500 mere destroyed by a fire which started in the repair shop of the G. W. Browne Motor Company, 228 Wisconsin street, Milwandee, Wis., on October 3. A repair men was working on a car with the aid of an extension light, when in some way the wires became short circuited and the marking flash ignited the fumes of a bucket of another standing nearby. Six of the cars in the garage were saved by the garage employees and others with considerable risk to themselves.

#### The Fairmount Park 200 Mile Stock Chassis Race.

The second annual running of this event, which took place Saturday, October 9, can unreservedly be said to have been a great success in every way, and much credit is due not only to the officials of the Quaker City Motor Club but to the city officials of Philadelphia, who lent their hearty cooperation by detailing 1,800 regular police, as well as the Fairmount Park Guards. It was stated that some 17 miles of rope was used to keep the spectators in check. Ambulances were placed at various points along the course, and besides various physicians who had come out to see the race flew Red Cross flags from their parked cars.

The sportsmanlike spirit shown by private owners and the local trade in entering cars despite the handicap of not having experienced racing crews did much to add interest to the race, and in many cases the performance of these cars, considered by themselves, was most meritorious. That the co-operation of the authorities with the club officials was thoroughly appreciated was shown by the disqualification of one of the entrants for an infraction of the park rules.

The course, which is located in Fairmount Park on the west bank of the Schuylkill, is peculiarly well fitted to bring out not only all desirable qualities in a car but also the skill of the driver. That portion of the course which includes City Line and Neill Drive is quite hilly and abounds in turns, while that portion from Sweet Briar Hill along the river affords a good opportunity to drive the cars to their limit. In short it would be difficult to find anywhere a course of equal length that would offer the same variety of conditions necessary to a thorough test of the qualities of a car that this

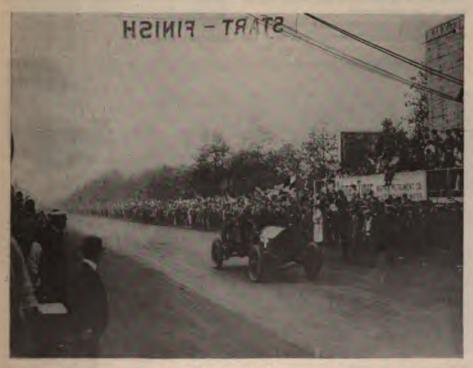

GENERAL VIEW IN FRONT OF GRAND STAND.

does, one so easily accessible and so easy to police.

On the morning of the race all of the twenty-two starters were on hand. Just before the race, however, Grant, who was to drive the Alco car, No. 11, discovered a slight imperfection in the steering gear. While a repair could easily have been made, Grant was inclined to err on the side of prudence and decided not to start. This was particularly unfortunate, as this car was looked on by many as at least a possible winner. A rather remarkable feature of this race was the large proportion of six cylinder cars entered, there being eight to a total of twenty-two.

Promptly at 12 o'clock the first car was sent away by the starter, and the others followed at fifteen second intervals.

The first trouble occurred to the Selden car. No. 23, which smashed a rear wheel at Sweet Briar Hill when hardly out of sight of the grand stand. A new wheel was fitted, and the car was running again after a delay of twenty minutes, and it was still going at the end of the race. Although on account of its number (23) this car furnished considerable merriment to the spectators, its performance was by no means bad, especially when it is considered that it was one of the lowest powered cars in the race. The Lozier also came to grief in this lap. A broken water connection caused a loss of the cooling water, and was not discovered until too late to effect a repair. In the meantime No. 2, American, had passed No. 1, Simplex, but was closely followed by No. 4 Simplex, which had passed No. 2 and 3 at the end of the first lap. Buick No. 13 had moved up to sixth position, and in point of time was in the lead. This time lead was maintained until the fourth lap, which was then gained by Simplex No. 4, and maintained until the end of the race. At this point Chevrolet, the driver of No. 13, was reported to be delayed by engine trouble, and although he made a splendid fight to regain his lost position he was forced to withdraw in the twelfth round on account of a broken exhaust valve. In the meantime, however, Columbia No. 14 and Welch No. 20 had withdrawn in the third round. One of the most interesting features of the race was a three cornered battle between Chadwicks Nos. 16 and 18, and the Isotta No. 17. At first No. 16 had the best of it, and had a lead of eight minutes or so. In fact, this car made the fastest time for a lap in the race, this lap being made in 7 minutes 41 seconds. In the fourteenth lap its lead was

ROBERTSON (SIMPLEX) FINISHING.

DINGLEY ON CHALMERS-DETROIT, SECOND IN RACE, ON HOME STRETCH.

decreased, and it finally dropped out owing to lack of cooling water. No. 18 had been keeping at it with surprising regularity; it had been passed by No. 17 a number of times, but in the nineteenth lap it finally passed the Isotta, and maintained the lead until the end of the race. This duel was rather interesting in view of the relative weights and horse powers of the two cars, and the comparative skill of the drivers, the Chadwick being higher powered and heavier than the Isotta, and on the other band the Isotta was equipped with a four speed gear, and driven by Strang, a man who thoroughly understands the use of the same. A remarkable feature of the race was the large number of cars still running at the end, there being three cars running when the race was declared off, besides those which officially finished.

One of the features of Robertson's performance on the winning Simplex No. 4 was the extreme regularity of running. Barring the first lap, and the one on which he took on supplies, the variation from lap to lap was a matter of hardly more than eight to ten seconds. Another feature of his driving was his extreme caution in taking corners, the brake being applied so that at the turn he was moving with comparative slowness. Just before rounding a turn he would change to a lower gear and try to save time by rapid acceleration after making the turn rather than by taking chances in rounding the turn at too high a speed. This seemed to be the method used by all drivers who finished.

As far as could be ascertained there were only two accidents of anything like a serious nature on the course. The Acme No. 7 on its seventh round cast a tire while approaching the grand stand. This rolled along the ground, and bounded over the supply pit into the grand stand, striking a thirteen year old boy and stunning him. A machine with a surgeon was rushed to the spot, and the boy was carried to a hospital tent. Fortunately he was not badly injured; some time later he returned to his seat and enjoyed the finish of the race. Hayes, driving American No. 12, and Mechanician Johnson struck a telegraph pole on Sweet Briar Hill, and both were

thrown. Hayes was not injured, but Johnson was rendered unconscious. After being placed in the ambulance he soon recovered and helped Hayes repair the car.

One fact that was rather remarkable was the almost entire absence of tire trouble, Robertson, the winner, for instance, was entirely free from it, and only changed his tires as a precautionary measure while taking on supplies. The five cars which officially finished were:

First-Robertson, No. 4, Simplex; time, 3h. 38m. 58s.

Second-Dingley, No. 5, Chalmers-Detroit; time, 3h. 44m. 30s.

Third-Harding, No. 8, Apperson; time, 3h. 52m. 17s.

Fourth-Parkin, No. 18, Chadwick; time, 3h, 55m. 31s.

Fifth-Strang, No. 17, Isotta; time, 3h. 56m. 54s.

Besides these No. 10, Palmer-Singer, was on its last lap when the race was declared off, while No. 3, Benz, was still running, being on its twenty-third lap, while No. 23 was on its seventeenth.

The electric automatic timer made by the Warner Instrument Company was used for the time at a road race. The three leading cars were equipped with Michelin tires.

After the race an informal smoker was given by the Quaker City Automobile Club to the contestants, officials and other participants, to which various city officials and the press were also invited. Speeches were made by the mayor and the chief of police, as well as by the winning contestants. The proceeds from the race will be devoted to charity, among the beneficiaries being the Children's Aid Society of Pennsylvania; Pennsylvania Society for the Prevention of Tuberculosis, Rush Hospital, Free Hospital for Poor Consumptives and the White Haven Sanitarium.

At a meeting of the contest committee of the Quaker City Motor Club on Monday of this week, the Chalmers-Detroit car was awarded the consistency prize, and Bert Dingley, its driver, the Stetson prize of \$100 in gold. Len Zengle, who made the fastest lap in a Chadwick car in 7 minutes 41 seconds, will be presented with a gold watch for the feat. George Robertson (Simplex), the winner of the race, will receive \$2,500 in gold and the MacDonald & Campbell \$1,000 cup. All of the prizes are to be presented at Keith's Theatre on Thursday night in the presence of State and city officials.

#### A. A. A. Contest Board Acts on Protests and Issues Suspensions.

The contest board of the American Automobile Association met at the Engineers' Club, New York city, October 5 and 6, with the full board present, to consider the various protests on file.

The first protests before the board were those of H. O. Smith and W. H. Vandervoort, entrants of the Premier and Moline cars, respectively, against the findings of the technical committee on the two Pierce touring cars and the Pierce Runabout No. 108. Messrs. Vandervoort and Smith withdrew their pro-

CHADWICK AND BUICK TURNING INTO HOME STRETCH.

MAP OF RACE.

tests with the consent of all parties in-

The protest of the Jackson Automobile Company on the abandonment of the 300 mile race on August 21 at the Indianapolis Motor Speedway was next taken into consideration. After a full discussion it was "Resolved, that, as Referee S. B. Stevens' action in the matter was done with the consent of the contest board through its representative at the meet, C. W. Sedwick, and in accordance with Rule 53, page 13, of the 1909 Contest Rules, the action of the referee is hereby sustained." And as the Jackson Automobile Company had advertised that it won the 300 mile race at the Indianapolis Motor Speedway on August 21, 1909, despite the referee's decision of no race, and in violation of Rule 55, page 14 of the Contest Rules of 1909, it was further "Resolved, that the Jackson Automobile Company is hereby suspended from entering any contest until January 1, 1910."

After careful consideration of the Chicago Motor Club's request for fixed penalties and other changes for its endurance run it was "Resolved, that a sanction will only be granted under the contest rules adopted June 10, 1909."

In the matter of the Premier Motor Manufacturing Company's protest against the Quaker City Motor Club both parties thereto were represented. The protest was on the penalties imposed for time in checking at controls after the blockade at Giant's Despair Mountain. After a full presentation of the case it was found that the subject hinged on part of the instructions given the contestants by a representative of the club at the instruction meeting, wherein it was stated in substance that, owing to road conditions, if a blockade occurred to a contesting car by reason of a disabled car, the committee would take care of it, This left the matter of making up time or of establishing a new schedule entirely at the discretion of the contestants. and both methods were used after the blockade. In view of these facts it was "Resolved, that the protest of the PremLIST OF ENTRIES.

ier Motor Manufacturing Company be sustained."

Relative to the appeal of the Dayton Motor Car Company in the hill climb contest of the Automobile Club of Cincinnati two protests were entered against awarding the first prize to the Stoddard-Dayton car on the ground that the car was not a stock car in the meaning of the definition in the contest rules, and the referee decided in favor of the appellants. From the evidence submitted by the makers of the car the referee's decision was sustained by the contest board.

On the report of the referee of the Brighton Beach races of August 27, and of a member of the contest board present, the entrant and driver of S. P. O. Car No. 1 were each suspended to January 1, 1910, and the driver fined \$100 and suspended until the fine is paid.

#### N. A. A. M. Meeting.

The regular monthly meeting of the executive committee of the National Association of Automobile Manufacturers, Inc., held at the association's office on October 6, was attended by Messrs. W. E. Metzger, in the chair, Thomas Henderson, A. L. Pope, L. H. Kittridge, H. O. Smith, S. T. Davis, Jr., W. T. White, W. M. Lewis, C. G. Stoddard, Charles Clifton, W. R. Innis, Benjamin Briscoe, R. D. Chapin and S. A. Miles.

The membership of the Electric Vehicle Company was transferred to the Columbia Motor Car Company, represented by H. W. Nuckels. The membership of the Royal Motor Car Company was transferred to the Ropal Tourist Motor Company, represented by George J. Dunham. Frank Briscoe, representing the Brush Runabout Company; W. C. Johnson, representing the Waverley Company; W. H. Van Devoort, representing the Moline Automobile Company; R. H. Salmons, representing the Selden Motor Vehicle Company, and W. S. Austin, representing the Austin Automobile Company, were elected to membership.

The question of the advisability of amending the standard warranty was referred to a special committee.

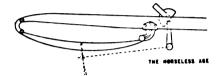

HARDING (APPERSON), WHO FINISHED THIRD.

# OUR FOREIGN EXCHANGES ➤

#### A Novel Front Spring Arrangement.

In the majority of cars fitted with semielliptic front springs the springs are pivoted at the forward end to spring horns secured to the frame side members, and at the rear are shackled to spring brackets riveted to the frame. This arrangement has one rather serious disadvantage, in that the play of the springs considerably influences the steering action. The axle being rigidly secured to the spring, when the latter compresses

DE DION FRONT SPRING DESIGN AVOIDING STRAIN ON STEERING GEAR.

and expands the axle moves in a circle around the pivot point of the spring horn as a centre. The steering rod, on the other hand, moves in a circle around the ball end of the steering arm and the two circles diverge considerably.

The above difficulty has been overcome in the latest De Dion small, four cylinder cars, in which the front springs are pivoted to the spring brackets and shackled to the frame at their forward end, as shown in the accompanying sketch. The centres of motion of the axle and of the forward end of the steering rod are then substantially the same, whereby the strains and abnormal wear, due to the differentiation in the radial movement of these parts are eliminated.

#### Chauffeurs and Their Masters.

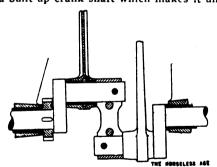

There are many thoroughly good paid drivers in the motor world. By good we mean honest, capable men who are properly qualified for their work. It is equally true there are a large number of incapable paid drivers, whose qualifications are very scanty, and who in one way or another are quite unfitted for the work, and very often their only recommendation is that they are cheap. On the other hand, there are all grades of employers, from the reasonable and considerate man to the unreasonable and suspicious individual that no man, whether he be honest and capable or dishonest and incapable, can satisfy.

There is no doubt that the grumbles on the part of the employers and on the part of the men are often real, and the grievances that both classes detail are not all imaginary. After all, a man can only speak from his own experience. If an employer has never succeeded in getting a good chauffeur he is apt to conclude that all chauffeurs are hopeless, and the chauffeurs in their turn who are unlucky in their masters arrive at the conclusion that reasonable employers exist only in story books.

We are glad to say that in the course of our motoring experience we have come across many motorists and men who have thoroughly understood each other, and whose relationship has been of a satisfactory nature, both to employer and employed. The difficulties which have arisen have undoubtedly been largely due to ignorance and consequent suspicion and unreasonableness on the part of the employer, and to incapacity and sometimes to downright dishonesty on the part of the employed. Imagine the position of an honest and capable chauffeur, who is engaged by a motor car owner who knows little or nothing about the car, and who has previously employed a man who has been proved to be either dishonest or incapable, or possibly both. Now, such an employer is so ignorant that he does not really know the difference between the good man and the unsatisfactory one, and consequently he fails to appreciatc or to trust either, so that no good man will stop with him longer than he can help. Then, again, there is the employer who knows how a car should be driven and how it should be looked after, but who, somehow or other, never seems to secure the right man. It may be urged that he is unreasonable, but while this is often true, we know in some cases it is not so. These things will right themselves gradually as the ignorant owners learn and as the incapable chauffeurs either mend their ways or turn their attention to other work.-The Autocar

### A Built Up Four Cylinder Crank Shaft.

The new four cylinder, 6-12 horse power light car built by the Adler Works, of Frankfort-on-Main, Germany, a description of which appears in the last issue to hand of *Der Motorwagen*. is provided with a built up crank shaft which makes it un-

ADLER BUILT UP CRANK SHAFT.

necessary to split the big end of the connecting rod.

The motor has a bore of 3 inches and a stroke of about 3½ inches. It will be seen from the accompanying illustration that the long arms of the crank shaft are separate pieces, which are clamped and pinned to extensions of the crank pins. The crank pins are approximately 1¼ inches in diameter, and the connecting rod bearing on the pins is 2 inches long. The part forming the long arm of the crank shaft is bored out at both ends to

receive the extensions of the pins, and is slotted between the bores. After the crank is assembled the long arms are drawn tight on the crank pins by means of two bolts passing through the arms close to the pins, and one pin is passed right through the middle of each crank pin and the surrounding arm. The object of this construction is evidently to save the cost of expensive dies for the crank shafts and the cost of fitting separate connecting rod heads.

### Daimler Motor With Rotating Disc Valves.

The Daimler Motor Company, of Unterturkheim, Germany, have taken out a French patent on a gasoline motor with rotary valves in the cylinder head. This motor is characterized by the fact that the cylinder head forms the seat for one or more rotating disc valves and contains inlet and exhaust ports. The valve discs are also provided with port openings, and are pressed against their seats by the pressure within the cylinder, which, together with the conical form of the seats, insures a gas tight joint. As the temperature in the cylinder is very high, the seats and discs are kept very small in order to prevent warping.

The patent specification shows a number of different constructions. The simplest construction is that in which a single rotating disc is used and the inlet and exhaust ports are arranged at 90 degrees to each other. In order to insure a quicker opening and closing of the ports two valve discs with concentric stems may be used and rotated in opposite directions. In order to insure perfect cooling of the discs the latter may be placed between interior and exterior water cooled walls. It is also possible to provide separate valve discs for the inlet and exhaust, in which case each valve can be timed absolutely independently, but the possible size of the valve ports is then rather limited. The stems of the valves have small gear wheels secured to them at their outer ends and are driven through a gear frame from the crank shaft at one-half the speed of the latter. One of the advantages of the system consists in the positive timing of the valves, and another one consists in their noiseless operation. Whether it is possible to keep these valves tight and to prevent cutting of the discs on their seats is a question only practical experience can solve.

It is reported from Paris that the majority of the executive committee of the A. C. of France are in favor of repeating the Grand Prix race in 1910. According to present plans there would be two races, one for large cars with four cylinder motors up to 30 mm. bore and up to 200 mm. stroke (5.2x8 inches), and one for small cars with four cylinder motors up to 90 mm. (3.6 inch) bore, or six cylinder motors up to 80 mm. (3.2 inch) bore.

### Commercial Test of a Pierce Water Cooled Motor.

At the last meeting of the Society of Automobile Engineers, in Chicago, a paper on the above subject was read by J. A. Luhrman and G. W. Woodward. The objects of the tests were to ascertain the following:

- I. The fuel consumption and the economic thermal efficiency at constant speeds and varied horse power output at various settings of the needle valve in the carburetor.
- 2. Fuel consumption and economic thermal efficiency at the maximum horse power output and varied speeds with respect to the needle valve settings.
- 3. The mechanical efficiency and maximum compression pressures from the manograph cards.
- 4. The fuel consumption for slow no load run.

The engine tested was a six cylinder Pierce engine of 315 inch bore and 434 inch stroke. The two sets of valves are located on opposite sides of the cylinders, and are actuated mechanically by separate cam shafts. It is not necessary to further describe the motor, as it is well known to most of our readers. Tests were made with a Hospitalier manograph and with a Prony brake, and the gasoline used was carefully measured. The gasoline was also analyzed by means of a Junker calorimeter, and was found to have a higher heating value of 19,798 B. T. U. per pound, and a lower heating value of 18,700 B. T. U. per pound. Following are sample computations for run No. 1:

10 horse power at 1,000 r. p. m.

Gasoline consumed in thirty minutes—4320 c. c.

Specific gravity-.705.

Since 4320 c. c. of gasoline were used, and I c. c. = .061 cubic inch, 4320 × .061 = 264 cubic inches were used.

As the hydrometer was calibrated with water at 60° Fahr., and the weight of 1 cubic foot of water at 60° Fahr.=62.37 pounds, the weight of gasoline=cubic inches × specific gravity × weight per cubic foot water + 1728=

$$\frac{264 \times 62.37 \times .705}{1728} = 6.72$$
 pounds.

B. T. U.'s supplied per hour = pounds of gasoline used × lower heating value of gasoline =

$$6.72 \times 2 \times 18700 = 251000.$$

Thermal equivalent of 10 horse power. Horse power  $\times$  2545 = 10.016  $\times$  2545 = 25460. Thermal efficiency =

Pounds of gasoline per 1,000 revolutions of motor = pounds of gasoline used + total revolutions × 1.000 =

$$\frac{6.72 \times 1000}{30050}$$
 = .2235 pound.

The volumetric efficiency from the card was determined by measuring the distance between the points where the compression

MAXIMUM I	JOESE LOME	Æ.		
	Run 1.	Run 2.	Run 3.	Run 4.
Time of run, minutes	15	20	20	15
Net brake scale reading	56.64	52.61	53.77	51.07
Gasoline consumed, cubic inches	154.8	249.2	414.5	258
Setting of needle valve (degree open)	360	360	450	450
Specific gravity of gasoline	.705	.705	.701	. 705
B. T. U. supplied per hour	294,000	356,500	575,000	490,000
Average D. H. P	20.54	25.8	32.58	38.65
Thermal equivalent of horse power	52,300	65,600	82,900	98,400
Thermal efficiency (D. H. P.), per cent	17.8	18.4	14.41	20.08
Total number of revolutions	<b>8,</b> 968	16,172	20,010	20,000
Revolutions per minute	579.87	808.6	1,000.5	1,250
Pounds of gasoline per 1,000 revolutions	-439	.259	.523	. 328
Temperature jacket water, in	111.89	113.7	88.09	89.5
Temperature jacket water, out	138.67	137.5	108.63	108
Temperature range	26.78	23.8	20.54	18.5
Pounds of jacket water per hour	4,608	6,000	7,260	<b>8,</b> 880
Heat loss to water per hour	123,300	142,800	149,100	164,200
Heat loss, per cent	41.9	40	25.95	33 • 5
Volumetric efficiency from card	85	87.50	77.03	94.25
I. H. P	17.85	25.20	29.90	38.25-
Maximum explosion pressure	294.66	251.08	<b>236.</b> 61	235.88

MANIANA HORES POWER

and suction lines cross the atmospheric line, and dividing this distance by the total length of the card. The average volumetric efficiency from the cards of the six cylinders was taken.

The indicated horse power of the engine was found by taking the sum of the indicated horse power of each cylinder.

#### PUMPING LOSSES.

The pumping losses = the difference between the I. H. P. from the indicator card and the B. H. P. =

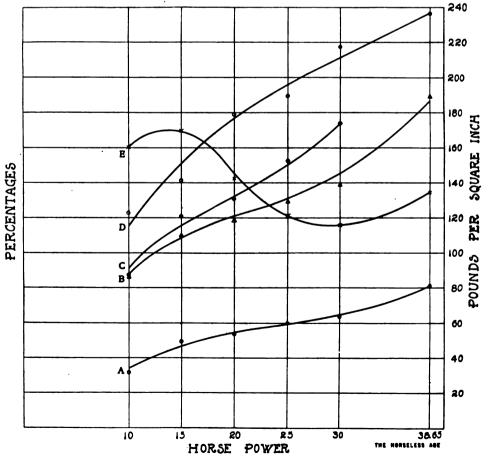

#### 18.75 — 10 = 8.75 H. P. MECHANICAL EFFICIENCY.

The mechanical efficiency is the ratio of

the D. H. P. to the I. H. P., and in this

$$\frac{10}{18.75} = 53.3 \text{ per cent.}$$

The authors of the paper give result sheets for runs at various outputs and speeds of revolution. We reproduce here only the result sheet of runs under maximum power at various speeds, which is undoubtedly the most interesting. We have, however, plotted in the diagram herewith curves showing the variation in the following factors with the horse power at a constant speed of 1,250 r. p. m.: Thermal efficiency, heat loss to jacket in per cent.,

A—Thermal efficiency, B—Volumetric efficiency, C—Mechanical efficiency, D—Explosion pressures, E—Per cent. of jacket loss.

volumetric efficiency from card, mechanical efficiency and maximum explosion pressure. The thermal efficiency will be seen to increase almost directly in proportion to the output. The volumetric efficiency, or the proportion of the cylinder filled, also increases substantially in direct proportion with the output, as does the mechanical efficiency. The percentage of heat loss to the jacket water shows a rather peculiar variation. It is lowest at about 30 horse power. The maximum explosion pressure increases with the horse power in an almost straight line relation, except at the lowest powers.

### Milwaukee Retail Firms Consolidated.

The Kopmeier Motor Car Company, of Milwaukee, Wis., has doubled its capitalization, its capital stock now being \$100,000. It has purchased the garage and business of the Ogden-Farwell Garage, incorporated for \$10,000. A. F. Timme, a well known young business man of Milwaukee, has acquired an interest, and will be general manager of both corporations, which will be operated as distinct companies. The list of officers of both companies is the same, as follows: President, Norman J. Kopmeier; vice president, A. F. Timme; secretary and treasurer, Waldemar S. Kop-The Kopmeier Garage, at 375 Summit avenue, will be distributor for the American and the Detroit electric as in the past, and has added the Velie. The Ogden-Farwell Garage, 82-86 Farwell avenue. takes over the Chalmers-Detroit and Hudson, heretofore handled by the W. L. Hibbard Motor Car Company, 417-421 Wells street, Milwaukee, and will be a subagency for the Detroit electric. Before the change of ownership the Ogden-Farwell Garage handled the Studebaker, E-M-F and allied lines. These have not yet been he-established in Milwaukee. The Hibbard Company is closing out its stock and will retire from the field. W. L. Hibbard retired from the company last July. The Kopmeier Company now controls the two most favored garages on the east side of Milwaukee, and it is said that plans are under way for the acquisition of at least one leading west side garage on upper Grand avenue. It already has a firm foothold in Chicago. Robert Drach is manager of the Chicago branch on Michigan avenue, which handles the American in that territory.

### Ajax Tire Company Increase Capital Stock.

The Ajax-Grieb Rubber Company, of Trenton, N. J., makers of Ajax tires, held their annual meeting last week. The annual dividend was declared, and it was voted to increase the capital from \$400,000 to \$1,000,0000. An election of officers for the ensuing year also took place, and all of the present incumbents were re-elected to the same offices. They are: President, Horace De Lisser; vice president, William

G. Grieb; treasurer, Harry Grieb. With the additional capital the company will be in a position to triple their capacity, and during 1910 they hope to do fully double the business of the present year, which has been the biggest in the history of the company.

### Large Independent Firms Join Licensed Association.

At the meeting of the Association of Licensed Automobile Manufacturers held in New York city on Thursday last, six of the largest outside manufacturers were admitted to membership, namely:

The Maxwell-Briscoe Motor Company.

The Reo Motor Car Company.

The Dayton Motor Car Company.

The Premier Manufacturing Company.

The Jackson Automobile Company.

The Mitchell Motor Car Company.

These six firms were admitted to membership on the condition that they pay a license of eight-tenths of one per cent. on the value of all cars manufactured by them to date, and the regular initiation fee of \$2,500. The meeting was well attended, all of the members of the Licensed Association, with one exception, being present. It was presided over by Charles Clifton, of the Pierce Arrow Motor Car Company, while M. L. Downs acted as secretary.

In addition to the above mentioned six firms the Overland Automobile Company, of Indianapolis, and Toledo, Ohio, has just joined the Licensed Association. By the purchase of the Pope-Toledo Motor Car plant, patents and good will, early last summer, the company acquired a membership in the Licensed Association, and it is under these rights, secured from the Pope Motor Car Company, that the Overland will operate in future.

Up to the present time the manufacturers of the Overland and Marion have been affiliated with the independent manufacturers, but in view of Judge Hough's recent decision, and in line with the company's policy of concentration, it has just been decided to manufacture the entire future product under one policy, that of the Association of Licensed Automobile Manufacturers.

The Buick Motor Company, of Flint, Mich., which has been a member of the Licensed Association since it was founded, but which some years ago refused to pay further royalties, has paid up all back royalties, and its good standing as a member has thereby been re-established. The Olds Motor Works, which were expelled about a year ago, have been taken back into the association.

### Pennsylvania Number Plate Contract.

The Pennsylvania State Highway Department will shortly open bids for the supply of automobile number plates for 1910. The tags will be of blue enamel, bearing the State name, year and license numbers in white letters. At one side there will

be a keystone of soft white enamel, which will bear the manufacturer's serial number, which latter is a new feature. Thirty-three thousand one hundred automobile tags have been sold in Pennsylvania so far this year, against 25,119 for the whole of last year.

### Eleven Entries for Brighton Beach Race.

At the time of going to press eleven entries have been received for the twenty-four hour race which is to be held on Brighton Beach track next Friday and Saturday, the latest entry being a Marion roadster, which is to be driven by Hugh Hughes and H. H. James. The other entries include two Lozier, Rainier and Buick cars, and one Fiat, Palmer-Singer, American Roadster and Matheson. It has been announced that the race is to be started by Dr. Frederick Cook, of Brooklyn, the Arctic explorer. Dr. Cook will be the guest of the Motor Racing Association.

#### Entries for Vanderbilt Cup Race.

Up to the time of going to press fourteen cars had been entered for the Vanderbilt Cup race, which is to be held on Long Island October 30. Most of the entries were the result of a visit of Manager A. R. Pardington and Fred J. Wagner to Philadelphia at the time of the Fairmount Park race. The entries include the following: Four Chalmers-Detroit, two Fiat, two Buick, two Nationals, two Simplex, a Moon and an Isotta. Two French Renaults are also expected. Entries close on October 25.

#### Business Troubles.

Wm. Henkel, Jr., has been appointed receiver for Walter G. Pierson, dealer in auto supplies at 43 Cortlandt street, New York. A petition in bankruptcy against Mr. Pierson was made by the following creditors: Cornelius D. McGiehan, \$250; Manhattan Screw and Stamping Works, \$147; A. R. Mosler & Co., \$86, and Indicator Sales Company, \$19. It was alleged that he is insolvent, made preferential payments to three creditors, and transferred his auto supply business to the Pierson Motor Supply Company, controlled by him and his wife. That company was incorporated on November 27, 1908, with a capital stock of \$20,000. He began business in 1898 as a publisher, and went into auto supplies about three years ago.

### Chicago Reliability Contest Abandoned.

The Chicago Motor Club, having been refused the change in the contest rules for which it petitioned the A. A. A., has abandoned its 1,000 mile reliability run, as it felt that it could not get a sufficient number of entries together under the old rules. A committee of the club will go to Detroit in the near future and lay the matter before Howard Coffin, chairman of the Manufacturers' Contest Association, with the object of securing a rehearing of the question on the part of the A. A. A contest committee.

#### MINOR MENTION

The Lexington Automobile Company, Lexington, Ky., will remove to Connersville, Ind.

The Boston Automobile Dealers' Association is holding its annual banquet today (Wednesday) at the Ferncroft Inn, Middletown.

In the Republic of Mexico 1,750 automobiles have been registered to date, of which no less than 1,500 are owned in the city of Mexico.

The Waterloo Automobile Parts Company, Waterloo, Ind., have started work on an 80x250 foot building on a 3 acre plot, which will be ready for occupancy January 1.

The dealers of Washington, D. C., held a meeting at the Regent Hotel on October 9 to consider the advisability of holding a local show after the New York and Chicago shows.

Welch Brothers Motor Car Company, of Milwaukee, agents for the Packard and Rauch & Lang electric, have taken the Continental tire and demountable rim agency for Milwaukee.

The Ditweiler Manufacturing Company, which has just been incorporated in Ohio with a capital stock of \$50,000, has located at Galion, and will manufacture a steering gear for automobiles.

The Auto Parts Manufacturing Company, of Muncie, Ind., have just completed the construction of a 60x125 foot saw tooth addition to their factory. They expect to triple their output this year,

It is reported from Salem, Ohio, that Sebring Brothers, owners of the pottery town of Sebring, west of Salem, will build an automobile factory for manufacturing six cylinder touring cars and runabouts.

The Midland Motor Company, East Moline, Ill., has discontinued the use of steam power in its plant and adopted electric power, deriving its current from the circuit of the United Light and Power Company.

The capital stock of the Wisconsin Motor Manufacturing Company, of Milwaukee, Wis., with a factory in North Milwaukee, has been increased by amendment to its articles of incorporation from \$35,000 to \$100,000.

The Precise Company, manufacturers of cam shafts and other automobile parts, will remove from Indianapolis to New Castle, Ind. The officers of the company are A. Afanador, president: John Parker, vice president, and Mr. Morgan, secretary and treasurer.

Tradesmen and private owners of Indianapolis will give a sociability run to French Lick and return Saturday and Sunday, October 16-17. The committee on arrangements is composed of Paul Smith, Frank B. Willis and Frank L. Moore. About thirty entries have been made. There will be two classes, cars costing above \$2,000, and cars costing under \$2,000. A hill climb will be given at French Lick.

The Majestic is the name of a new six cylinder, 90 horse power car to be placed on the market soon by the Milwaukee Auto Engine and Supply Company, 706 and 708 Winnebago street, Milwaukee, Wis.

The seventh annual contest for the Brazier Cup will be held over a circuit to the north of Philadelphia, starting and ending at that city, on next Saturday afternoon, October 16. The course will be 60 miles in length.

A new building 50x105 feet is to be added to the Niagara Falls, Ont., branch works of the Acheson Graphite Company. The new building will contain a grinding plant, a stock room for package goods and a shipping room.

Chas. E. Miller, the well known automobile supply dealer and jobber, announces that he will open a branch at Atlanta, Ga., about November 1. This makes the tenth store operated by Mr. Miller for the sale of automobile accessories and supplies.

The Salem Iron Works, of Winston-Salem, N. C., have decided to take up the manufacture of motor delivery wagons, which will be equipped with a drive invented and patented by C. A. Hege, president and principal owner of the company.

The plant of the Badger Motor Car Company at Columbus, Wis., is rapidly nearing completion, and at least part of it will be occupied soon. The company is building its first models in the large garage of Roberts & Smith at Columbus, which it has leased temporarily.

The new Marion, Ind., works of the Western Motor Works were started on October 5. The company's main factory is located at Logansport, Ind. The tool department of the new factory was started first, and within a short time all of the other departments will be in operation.

The Salisbury Auto Wheel Company, of Jamestown, N. Y., will remove to Peru, Ind., where it will occupy the old Brownell booth works. The company has contracted with the Commercial Club of Peru to buy the plant and equip it with \$40,000 of machinery, whereupon Peru investors will put \$60,000 into the company.

A sixth story has been added to one of the larger buildings of the Franklin plant in Syracuse, which added 15,900 square feet of floor space and doubled the space occupied by the paint shop. Upon the completion of the addition the number of enameling ovens was increased from three to eleven and the rubbing deck space was doubled. The new ovens are all of brick.

The Motor Racing Association of New York has under consideration a plan for making the Brighton Beach Motordrome a permanent establishment. The association has a lease on the property which does not expire until the middle of July next, and under certain conditions it may be renewed.

It is at present being planned to build a steep hill in the infield for hill climbs, and to erect permanent buildings for competing crews, a new field stand and a large garage.

The Board of Supervisors of Nassau County has granted permission to hold the Vanderbilt Cup race on October 30, which removes the final obstacle to the running of the event.

The International Engineering Company, of 1779 Broadway, New York, have secured the exclusive agency for R. B. F. ball bearings, made by the Société Française des Roulements à Billes. Lavalette & Co., who formerly handled these bearings, have relinquished the agency.

The contest committee of the Bay State A. A. have changed the dates of the association's annual reliability run from October 22-23 to October 21-22, so that the results of the contest can be announced on Saturday, October 23. The entry blanks were sent out on October 8.

It is reported that interests connected with the General Motors Company have incorporated a new concern under Maine laws to do an automobile supply and garage business in all parts of the United States. The main office of the parent company is to be in Saginaw, Mich.

The additions to the factory of Gray & Davis, of Amesbury, Mass., have been practically completed, and are partially occupied. They comprise an addition of two stories to one of the wings of their main building, and two new buildings, one for annealing and the other a dyehouse.

The Atlanta (Ga.) Auto Trade Association at a meeting held on September 25 agreed upon prices to be charged for garage service during the Atlanta automobile week, November 6 to 13, inclusive. The schedule of prices can be obtained from Col. F. J. Paxon and S. C. Dobbs. A committee was appointed to look for buildings in the city that might serve as emergency garages, if such should be necessary.

The new Atlanta automobile track is now practically completed, and the surface is now being put in condition by applying road oil. The grand stand and "bleachers" are completed, as are also the judges' stands, press stands, tire pits, administration buildings, garages, etc. An opening exhibition is to be given on the track on October 23, in which Robertson, De Palma and Basle are to take part.

The Fidelity Motor Car Works, of Sycamore, Ill., have finished their first car. F. C. Binkley, who was formerly connected with the Turner Brass Works, is president of the new company, Byron J. Snow is, vice president and A. L. Ellwood secretary. The car was designed by J. F. Waters, who occupies the position of factory superintendent. The car is a one ton delivery wagon, and is equipped with a 20-25 horse power, two cylinder water cooled Davis engine. It has a wheel base of 80 inches, 32 inch wheels and 3 inch Swinehart solid rubber tires. The company plans to build five different types of comercial vehicles.

#### Club Notes.

Seventy-five new members were elected to the New Jersey Automobile and Motor Club at Newark during the month of September. The organization now has nearly 1,800 members.

A movement is on foot in Texas for forming a State automobile association. The San Antonio (Tex.) Club, which seems to be leading in the movement, has appointed Dr. Frederick J. Fielding to represent it in the work of organization.

The Peoria Motor Cycle Club has been formed in Peoria, Ill. The club has about fifty members at present, and plans to hold a race meeting the coming fall. The officers are T. Van Buskirk, president; Earl Shanmeyer, secretary and treasurer, and Milton Hitchcock, captain of club runs.

The Milwaukee Automobile Club has a membership of 355, assets of \$0,000, a cash balance of \$2,650, and owns real estate of much value, according to the annual report of President Clarke S. Drake. It was urged at the annual meeting last week that the proposed clubhouse be built at once.

Motorists of Franklin County, Mass., are planning to form a county association. At a recent meeting in Greenfield, which was presided over by F. E. Snow, a committee was appointed to appear before the State Highway Commission to make an appeal for an allotment of State money for road improvements in the county.

The Sea Isle City Motor Club has been formed at Sea Isle City, N. J., with a charter membership of thirty, and the fol-lowing officers: Charles Woertz, president; Bismarck Kiesswetter, vice president. and Walter Brooks, secretary and treasurer. The new club plans to affiliate with the associated automobile clubs of New Jersey.

The Lake County (Ohio) A. C. was formed at a meeting held in Painesville, Ohio, on October 6. The following officers were elected: E. L. House, president: E. D. Heartwell, vice president; A. W. Colby, secretary and treasurer. The new club will direct its first efforts to securing the improvement of certain roads in Painesville

The Sioux City (Ia.) A. C. is planning to hold an automobile show during the coming winter. A building has not yet been secured, but the Auditorium and the Boston Block are being considered. The club has named a committee to confer with the committee of the Iowa State Automobile Association on matters affecting the two organizations.

The Delaware Automobile Association held a meeting on October 4 and elected the following officers: J. Danforth Bush. president; A. D. Hazzard, vice president; Chas. G. Guyer, secretary; Walter Stanier, treasurer. The association is deeply interested in the improvement of roads in Kent and Sussex counties, and maps of the roads of these counties were shown at the meeting which will be incorporated in the next issue of the association's year book.

Garage Notes.

The Studebaker Automobile Co. is reported to be planning the establishment of a garage in Eau Claire. Wis.

A salesroom for the Empire "20" has been opened in Chicago at 1456 Michigan avenue, in charge of W. H. Chadburne.

The Roman Automobile Co., of Philadelphia, have opened a branch in Washington, D. C., at 1315 and 1317 H street, N. W.

J: H. Morgan has bought a building on Stevens street, Rhinelander, Wis., which he will open as a garage next spring. Mr. Morgan's son Gordon will have charge of the garage.

It is reported that the Roach-Leppo Auto Co.,

Madison, Wis., have disposed of their garage business to A. O. Melaas, of Madison. Mr. Melass will handle the Maxwell exclusively.

A stable at 2 West Ninetieth street, New York city, which was erected only two or three years ago, is to be converted into a garage. The alterations will cost in the neighborhood of \$4,000

W. C. Edmonds, of 2304 St. Paul street, Baltimore. Md., has let the contract for the erection of a garage in the rear of his residence. be a frame building covered with galvanized iron.

Plans are being prepared for the erection of an automobile garage and store building on the East Side in Portland, Ore., at a cost of \$30,000. garage will be one story, 50x200 feet, of brick and

The Electric Auto and Battery Co. has been organized in Minneapolis, Minn., to conduct a garage for electric cars. C. L. Dobbs is manager, and the company has decided to locate at 717 Hennepin avenue.

E. R. Howard and L. M. Cregor, Nashville, Tenn., have leased the building at 135 Third avenue, and will open a garage there on October 15. They will have the agency for the Chalmers-Detroit and the Hugson cars.

The firm of Enos & Brandfield, vehicle dealers. of Grand Rapids, Mich., have entered the auto-mobile field and secured the agencies for the Jackson and Fuller cars. They are at present looking for a garage.

E. K. Spoonheim and A. C. Riddell have organized the Spoonheim-Riddell Motor Sales Co. in Northwood, N. Dak. They have incorporated with a capital stock of \$10,000, and will handle the Halladay and Empire cars.

The Northland Motor Car Co. have recently been organized in Minneapolis, Minn., and have secured the agencies for the Stoddard-Dayton and the Fal cars. The company have secured headquarters at 907 Hennepin avenue. E. E. Houk, Nashville, Tenn., has had plans

prepared for a two story fireproof garage, with sufficient floor space for storing 100 cars. Houk has the agency for the White steam and gasoline lines, and for the Hupmobile.

The firm of Westover & Fulton, Beatrice, Neb., has been dissolved by the withdrawal of Mr. Westover, and the business will be continued by F. Fulton under the style of the Fulton Auto Re-The company's business is located on pair Co. East Court street.

The firm of Wilson & Buffington has been formed at Los Angeles, Cal., to handle the Thomas car in southern California, and they have taken over the Thomas garage at 844 South Olive street. A. S. Robinson wil be sales manager of the new company.

The Corker Co., Atlanta, Ga., have let the contract for a four story 50x100 brick garage building on James and Fairlie streets. The building is to have concrete floors throughout, and will be equipped with all modern garage conveniences. It is to be ready for occupancy December 15.

The Maxwell-Briscoe Motor Co. have opened a factory branch in Omaha, Neb., in charge of Louis T. Doty. An office has been opened at 312 South Eighteenth street, and a garage is being erected for the company on Farnam street. is a two story and basement building 50x120 feet.

The Hamilton Automobile Supply Co. has been organized in Chattanooga, Tenn., with E. G. Skinner as manager. Quarters have been secured in the Thomas Fritts Building, in which the company will operate a garage to be known as the

Crescent Garage. The Overland line will be handled.

O. S. Hubbard, of Hillside avenue, Newton,

Mass., is erecting a garage.

The Broadway Roller Rink, Superior, Wis., is being converted into a garage.

Zantzinger & Borie have let a contract for the erection of a garage in Cynwyd, Pa.

The New Stratman Vehicle Co., Boyceville, Wis. are to establish a garage in that city.

G. H. Jacobson is organizing a stock of to build and operate a garage in Beresford, S. Dak. Frank T. Meagher, of Blue Hill avenue, Milton, Mass., has purchased the garage at Mattapan square.

C. W. Bixby. Wilkes-Barre. Pa., has filed plans for the erection of a one story brick garage at 20 West South street.

The Cataract Power & Conduit Co., of Buffalo, N. Y., are to erect a garage at 970 Front avenue, at a cost of \$4.000.

W. M. Kerr, Carlsbad, Tex., is erecting a 75x100 foot brick garage opposite the Reclamation Building, to cost \$60,000.

A one and a half story brick garage is being erected for A. R. Snowden on Fifth avenue, near Moorwood avenue, Shadyside, Pa., at a cost of

Walter H. Robinson, St. Joseph, Mo., expects to abortly occupy the garage now in course of erection at Thirteenth street and Frederick avenue, St. Joseph, Mo.

E. Holtz will open a garage and repair shop in the Barry Building, Paynesville, Mina. He will handle the Buick, Maxwell, Res and Overland cars.

A garage and hardware store is to be built on Sixth avenue, north of Forest avenue, Des Moines, Ia., for James C. Heath, who intends to combine both businesses.

The E. B. Thompson Co., Pittsburg, Pa., has let a contract for the erection of a reinforced concrete garage on New Louise street, at a cost of about \$40,000.

The firm of Gould & Blossom, St. Johnsbury, Vt., known as the Union Garage & Machine Co., has dissolved partnership. H. B. Blossom will continue the business.

The Jacksonville Automobile Co., Jacksonville, Ill., are about to erect a garage adjoining the post office. The building will comprise a repair shop and salesroom.

Plans are being drawn for the erection of a 50x 150 block brick garage on First street and Scott avenue, Fort Scott, Kan., for Col. W. A. Cormany and W. H. Robinson.

The Ingraham Automobile Co. has been organized in Denver, Col., by W. H. Ingraham and S. L. Bierbauer to handle the Lane steamer. The company plan to open a garage in the business section.

John W. DuBois, of Swedesboro, N. J., has sold his livery stable, which will be converted into a garage. Mr. DuBois will establish an automobile service for traveling men and for those who desire to attend social functions.

Denis B. Duane and J. Schiltz have purchased the Auto Construction Co. garage and machine shop in Rochester, Minn., from Roger H. Mills, The new owners will conduct the business under the name of the Rochester Specialty Co., and will carry a complete line of accessories, in addition to handling the E-M-F, the Flanders Twenty and the Reo cars.

The Petrie-Phillips Automobile Co. has been or ganized in St. Louis, with C. G. Petrie as preident, Jerome Phillips as treasurer, and Roy F. Britton as sccretary. They have reased a building at 1127 Olive street for a term of years, which is now being remodeled, and will be occupied by the company about October 10. The new firm will handle the Parry car.

Lawrence and Benjamin Gottfredson, of Green Bay, Wis., will withdraw from active interest in the Gottfredson Brothers Company, wholesale hardware dealers, on January 1, in order to devote their entire attention to the motor car industry. The company recently established a garage and agency in connection with the bardware business, and will now conduct the auto business

separately. H. L. Everson, of Mariette, Wis., will be associated with them.

W. T. Dill, New Haven, Conn., is having a brick parage erected on Crown street.

Roger H. Mills, 324 South Main street, Rochester, Minn., has sold his garage to Jake H. Schiltz.

Stanley A. Dwight has completed the construction of a garage at 174 Ionia street, Grand Rapida, Ia.

Ed. Dealy and T. F. Quigley, of Maurice, Ia., have rented a building in Le Mars, where they intend to open a garage.

A one story brick garage is to be erected by the Sarah L. Coffin estate, San Francisco, Cal. The estimated cost is \$14,000.

The Regal Motor Sales Co., Cleveland, Ohio, have opened a new salesroom at 1256 Euclid avenue, in charge of G. C. Hipp and F. B. Gott.

R. A. Parker, of Toledo, Ohio, has purchased Gus Uhl's interest in the Standard Garage. Mr. Parker will continue the business along the same lines.

The Gillis-Strickland Motor Co., of Rochester, N. Y., have bought a property at 96 Clinton aveeue South, on which they will erect a showroom and garage.

Harry A. Davis and Whitney A. Clark, Utica, N. Y., have leased a garage at 12 West street, and secured the Oldsmobile agency for Oneida and Herkimer Counties.

The Maxwell-Briscoe-Toledo Co., Toledo, Ohio, expect to occupy their new garage on Madison and Tenth streets early in November. W. H. Mc-Intyre will be manager.

A new building is to be erected for the Chicago branch of the E. R. Thomas Motor Co. at 2257-9 Michigan avenue. Plans for the building are at present being drawn.

The Cox Automobile Co., Harrisburg, Pa., expect to occupy their new garage on South Fourth atreet within the next ten days. They handle Stoddard-Dayton and Herreshoff cars.

The Foss-Hughes Motor Car Co., of Philadelphia, Pa., will open a garage and showroom at Newport, R. I., which will have accommodation for 275 cars. They are Pierce-Arrow agents.

Charles and Jennie Crocker, San Francisco, Cal., have obtained a permit for the construction of a one story brick garage on First street, south of Mission street. The building will cost \$18,000.

The new firm of Sheagrean & Hunt, Burlington, Ia., have opened a garage and salesroom on the corner of Fourth and Washington streets. They will carry a full line of auto and launch accessories.

W. H. LaFountaine, a Pittsburg automobile dealer who left that city about a year ago on account of ill health, has returned there and reengaged in the auto business on Baum street, East End.

The St. Louis-Stearns Automobile Co. has been organized in St. Louis, Mo., to handle the Stearns cars in that territory, and a salesroom has been opened at 1210 Olive street las week, in charge of "Jack" Dunwoodie,

L. J. Wells, of Wells Livery Co., Des Moines, Ia., plans to open a garage in connection with his livery business. A new seven story building for the purpose is now in course of construction at Ninth and Mulberry streets.

J. J. Harter, Sac City, Ia., has taken over the

J. J. Harter, Sac City, Ia., has taken over the automobile end of the business of Harter, Wilson, Brownell & Co., implement dealers. Mr. Harter will open a garage and salesroom and will handle a number of lines of automobiles.

The Toledo-Mitchell Co., Toledo, Ohio, have taken over the garage of the Central Auto Co., said to be one of the oldest garages in that city. The building will be remodeled and put into shape to meet the requirements of the new company.

The C. B. Brokaw Auto Co., of Plainfield, N. J., have taken over the Morris Brothers garage on East Fourth street, which was established in May, 1905. The members of the new firm, which has been incorporated with a capital stock of \$25,000, are Clarence B. Brokaw and Alonzo Brokaw, of Plainfield, and Walter B. Hopping, of New York. Clarence Brokaw was formerly instructor of the

West Side Y. M. C. A. Automobile School in New York city.

The recently incorporated Automobile Supply Co., of Tacoma, Wash., have moved into their new quarters at 757 South C street.

The Tacoma Motor Car Co. occupied its new quarters at 750-2 South street, Tacoma, Wash., on October 4. They handle the Oldsmobile.

The Northwestern Automobile Co. will open a garage on North Twenty-first street, Tacoma, Wash., on October 15. The building will consist of four stories.

On October 1 the Dover (N. J.) Garage passed into the control of R. A. Bennett, the former proprietor, W. Schumann, having severed his connection with the same.

The Joslyn Automobile Co., who handle the Rambler in Rockport, Ill., are planning to erect a 50x150 foot two storage garage. A site for the building has been secured.

An automobile showroom is to be installed at 1281/2 Bedford avenue, Brooklyn, N. Y., in a three story, 20x107 foot building, formerly occupied by the Long Island Wheelmen's Club.

The Ford Motor Co., of Detroit, Mich., have established a factory branch in Atlanta, Ga., with M. C. Huie as manager. Mr. Huie handled Ford cars in Atlanta for a number of years.

E. R. Clark, Atlanta, Ga., has taken the Georgia agency for the Elmore car, and opened a salesroom on the ground floor of the Masonic Temple. The Elmore Motor Car Co. will be organized by Mr. Clark to handle the car in the State.

The Western Automobile Co., Portland, Ore., have secured temporary quarters in the building of the Covey Motor Car Co. at Seventh and Couch streets. Elliott E. Breet will be manager of the new concern. They will handle the Knox car.

The Newby Automobile Co., of New Castle, Ind., is to be reorganized as the Maxwell-Briscoe-Newby Co., and will handle in the future only Maxwell cars and automobile supplies, discontinuing the sale of sporting goods. J. A. Newby will continue as manager.

A garage, repair shop and district agency will be established at Dodgeville, Wis., by the New Stratman Vehicle Co., wagon and carriage makers, as an auxiliary to the vehicle factory. It is planned to engage a factory expert to handle this department.

The Bryant Motor Co., Youngstown, Ohio, has opened its new garage on Jefferson street. The building is equipped with every modern convenience. The garage proper has a floor space of 36,000 square feet. The company handles the Chalmers-Detroit and Hudson cars.

W. A. Voigt and A. G. Maurer. of Sheboygan, Wis., have commenced the erection of a garage on Niagara avenue, Sheboygan. The building will be two stories high, 60x150 feet. The shop will be 50x60 feet, and will be ready by December 1. The remainder of the building will be erected slowly through the winter.

The Apperson Brothers Automobile Co., whose Chicago branch is now located at 1240 Michigan avenue, have taken a lease on a property at Thirty-third street and Indiana avenue, on which a modern three story building is to be erected at a cost of about \$30,000. The lease runs for ten years, at an annual rental of \$4,000.

A co-operative partnership has been formed between Henry F. Bechman, Stephen Rathbun and ex-Mayor Chas. C. Green, of Battle Creek, Mich., to be known as the American Motor Co. The new company will occupy the garage formerly conducted by the American Motor and Cycle Co. as soon as that company's affairs are adjusted. Ed. Hurley and Bob Winslow, Fort Smith,

Ed. Hurley and Bob Winslow, Fort Smith, Ark., have formed the Hurley-Winslow Automobile Co., and let the contract for a two story brick garage at North Seventh and A streets, to cost in the neighborhood of \$20,000. Ralph Lindbloom, of Minneapolis, will have charge of the mechanical department. The company plan to secure the agency for several lines of cars.

George W. Hanson, who handles the Studebaker and Benz cars in Atlanta, Ga., has taken a lease on a garage which is at present being built at 45 Auburn avenue by Chas. Black. This is not an entirely new building, as part of it is reconstructed from an old building. The garage when completed will be \$5x100 feet, and will have a show room in front and storage room in the rear.

The St. Louis House of Delegates has passed a bill authorizing the J. H. Philips Automobile Co. to establish a garage for electric vehicles at 5019 Delmar boulevard. A great deal of opposition was made to this bill by residents in the district.

The Newbold-Speedwell Co. has been organized to handle the Speedwell car in Washington, D. C., and have secured quarters in the building of the Warner Motor Co. on New Hampshire avenue. The members of the firm are John F. and Fleming Newbold.

Very little change will be made in the 1910 agencies in Indianapolis. Among the most important will be the fact that the Fisher Automobile Co. will relinquish the Maxwell agency, and the Maxwell-Briscoe Motor Co. will establish a sales branch. The Hupmobile, which has been handled by the Indiana Automobile Co., has been taken by the Hearsey-Willis Co.

The Jacksonville (Fla.) Motor Car Co. are erecting a modern garage at the corner of Clay and Church streets. The building will be of brick, 105x52 feet, and will accommodate fifty cars. Those interested in the company include S. A. Morris, Chas. Sloan, W. M. Musar and Thos. J. Mason. The company desires to secure the agency for several lines of cars for southern Georgia and Florida.

#### New Incorporations.

Albany Garage Co., Albany, N. Y.—Capital stock increased from \$50,000 to \$100,000.

The Buffalo Maintenance Co., Buffalo, N. Y.— Capital stock, \$5,000. To deal in automobiles and

auto sundries.

The McLaughlin Motor Car Co., Toronto, Canada, has increased its capital stock from \$300,000
to \$1.200,000.

Augusta Garage and Supply Co., Augusta, Ga.— Capital stock, \$15,000, with the privilege of increasing it to \$50,000.

Des Moines Auto Gas Co., Des Moines, Ia.— Capital stock, \$10,000. Incorporators, W. B. Jeffrey and L. D. Wohrer.

Auto & Taxicab Co., Los Angeles, Cal.—Capital stock, \$25,000. Incorporators, C. J. Black, R. C. McClay and J. W. Owen.

Nolan Garage, Los Angeles, Cal.—Capital stock, \$20,000. Incorporators, Geo. N. Nolan, Jr., L.

M. Nolan and Thos. Hopkins. The Cleveland Automobile School Co., Cleveland, Ohio.—Capital stock, \$10,000. Incorporators,

Clyde H. Pratt and W. H. Pettibone.

The Marshall-Clark Motor Car Co., Louisville,
Ky.—Capital stock, \$20,000. Incorporators, R. H.
Edelen, F. S. Clark and T. L. Marshall.

The Motor Sales Co., Grand Forks, N. Dak.— Capital stock, \$10,000. Incorporators, E. K. Spoonbeim, A. C. Riddle and P. K. Spoonbeim.

The C. B. Brokaw Auto Co., Plainfield, N. J.— Capital stock, \$20,000. Incorporators, Clarence Brokaw, Alonzo F. Brokaw and Walter B. Hopning.

General Motor Car Co., Ltd., St. Louis, Mo.— Capital stock, \$20,000. Incorporators, J. A. Hutchison, H. C. Gottfried, C. H. Smith and Sidney B. Cohn.

Pomona Auto Agency and Supply Co., Pomona, Cal.—Capital stock, \$20,000. Incorporators, E. C. Bichowsky, E. L. Downing, B. M. Ledeger, E. A. Rhodes and F. V. Bichowsky.

Auto Parts Manufacturing Co., Peru, Ind.— Capital stock, \$200,000. Incorporators, S. H. Penfield, Benjamin S. Dean, E. D. Shearman, Fredk. Brown, Jr., and John Tomey.

Brown, Jr., and John Tomey.

Holdeman Motor Car Co., Hutchinson, Kan.—
Capital stock, \$25,000. Incorporators, J. H. Holdeman, W. H. Boots, H. B. Holdeman, Geo. Wallace,
William Brown and F. E. Hollinger,

Berkshire Auto Car Co., Springfield, Mass.— Capital stock, \$120,000. Incorporators, John Mc-Quaid, Clement F. Coogan, William J. Mercer, John White, Michael Casey, Oscar S. Roberts, Edward B. Belcher and Henry I. Ryan.

ward B. Belcher and Henry J. Ryan.

The Republic Motor Car Co., of Hamilton, Ohio, has filed an amendment to its incorporation papers,

changing its preferred stock of \$250,000 to common stock, making the total of the common stock issued \$500,000.

The Webb Motor Co., Denver, Col.—Capital stock, \$10,000. Incorporators, B. R. Webb, Samuel I. Monarch and M. J. Dorsey.

Ideal Auto Co., Fort Wayne, Ind.-Capital stock, \$25,000. Incorporators, F. K. Safford, M. F. Jones, Geo. B. Hall and M. J. Plitz.

Royal Garage and Taxicab Co., Atlantic City. N. J.-Capital stock, \$50,000. Incorporators, P. D. Royal, W. H. Conn, C. E. Sesinger.

#### Trade Personals.

- S. W. Croxton, Jr., has been appointed to the position of manager of the publicity department of the Croxton-Keeton Motor Co., Massillon, Ohio.
- E. Thomas Keenan, recently manager of the Scranton Automobile Co., Scranton, Pa., has accepted the position of manager of the Hart-Kraft Motor Co., York, Pa.
- H. C. Henderson, who has been connected with the Thomas factory at Buffalo, N. Y., for a number of years, has joined the selling forces of the E. R. Thomas Motor Branch Co. in Boston.

Frank Dunn, who for seven years was connected with the Diamond Rubber Co., has joined the Cleveland branch of the Michelin Tire Co., and will have charge of the office and of local sales.

- L. L. Fest, of Chicago, who will act as assistant to Managers S. A. Miles and Alfred Reeves in the conduct of the Atlanta Show, has arrived in Atlanta, and has taken up active work in connection with the show.
- W. J. Urquhart has assumed the position of general manager of the Western sales department of the White Co., with headquarters in Chicago, succeeding C. A. Hawkins. Mr. Urquhart was formerly assistant sales manager.

Wm. H. Pickens, who has managed the Buick racing team the present season, has resigned from that position, and Louis Strang, one of noted drivers of the Buick Motor Co. (Chevrolet, Burman and Strang), is reported to also have left the company to join the Isotta Import Co.

Wm. F. McGuire, who was manager for the receivers of the Consolidated Manufacturing Co., Toledo. Ohio, for the past three years, will sever his connection with that firm and assume a managerial position with the Ford Motor Co. of Detroit, Mich., on November 1.

R. S. de Mitkiewicz, member of the gas power section of the American Society of Mechanical Engineers, formerly with the Fairbanks Co. in gas power work, has become connected with the Alden Sampson Manufacturing Co., of Pittsfield, Mass., manufacturers of motor trucks and road Mr. de Mitkiewicz will be associated with their New York office, 115 Broadway, as power sales engineer in mechanical transportation.

#### New Agencies.

Omaha, Neb.-C. F. Louk, Fal. Des Moines, Ia.-L. J. Wells, Moon. Chicago, Ill.-Hart Motor Co., Gaeth. Seattle, Wash.-C. S. Cummings, Regal. Pittsburg, Pa.-Martin & Mars, Rambler. Fort Worth, Tex .- Wood & Wood, Buick. New Orleans, La.-H. R. Kron, Peerless. Kramer. Ind.—Joseph Rice, Great Western. Winston, N. C.—The Motor Co., Studebaker. Rugby, N. Dak .- John Swanson, Overland. Syracuse, N. Y.-Willis & Van Brunt, Oakland. Washington, D. C.—The Wilson Co., Hupmobile. Washington, D. C .- The Wilson Co., Hupmobile.

North Yakima, Wash.-Alex, E. McCredy, Winton.

Washington, D. C .- Pope Automobile Co., Oakland.

Minneapolis, Minn.-The Robertson Motor Co., Franklin.

Toledo, Ohio.-The Banting Machine Co., Grabowsky truck.

Los Angeles, Cal.-Messenger-Low Auto Co., Sharp-Arrow.

Brooklyn, N. Y.—Standard Auto and Sales Co.,

1281 Bedford avenue, National, Empire and Oak-

Vancouver, B. C .- British Columbia Automobile Co., Winton,

Burlington, Ia.—Seagrean & Hunt, Chalmers-Detroit and Hudson.

#### Trade Literature Received.

The Waverley Co., Indianapolis, Ind.—Catalogue of Waverley electric carriages for 1910.

S. C. Partington, 422 Prospect Avenue, Buffalo, N. Y.-Circular of the Automatic Automobile Protector.

Pierce-Arrow Motor Car Co., Buffalo, N. Y .-Book entitled "A Month in Europe with a Pierce-Arrow Car."

The Stark Rolling Mill Co., Canton, Ohio.-Catalogue of Alumaloyd, a sheet metal for automobile construction.

E. R. Thomas Motor Co., Buffalo, N. Y .- Reprint of a description of the Thomas Flyer, Model M, from one of the trade papers.

Premier Motor Manufacturing Co., Indianapolis, Ind .- Booklet intended for Premier agents, containing a digest of a talk by Albert J. Stocker at the recent Indianapolis convention of Premier

National Brake and Clutch Co., 16 State Street, Boston, Mass.—Reprint of a paper recently read before the National Association of Cotton Manufacturers on "Cork Inserts as Applied to Textile Machinery."

#### Coming Events.

October 15-16-Twenty-four hour race on Brighton Beach Track, Long Island, New York Motor Racing Association, New York City.

October 16-Philadelphia, Pa., Race for Brazier Cup.

16-17-Indianapolis, Ind., Run to October French Lick and return.

October 21-22—Boston, Mass., Reliability Run, Bay State A. A.

October 23-Oakland, Cal., Road Races, A. C. of California

October 30-Vanderbilt Cup Race, Long Island

Motor Parkway, Long Island, N. Y.
November 1—Indianapolis, Ind., Race Meet, Indianapolis Motor Speedway Co.

November 6-13-National Automobile Show, under the auspices of the N. A. A. M., at Atlanta, Ga.

November 9-Atlanta, Ga., Track Races, Atlanta Automobile Association.

November 20-21-New Orleans, La., Two Day Track Race, New Orleans A. C.

November 22-Flag-to-Flag Reliability Run, from Denver to City of Mexico.

December 29-30-Philadelphia Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7-New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

January 8-15-New York Annual Show, Madison Square Garden, Association of Licensed Automobile Manufacturers.

February 5-12, 1910-The Ninth Annual National Show at Chicago, Ill.

February 22-26-Kansas City, Mo., Fourth Annual Show, Convention Hall, Kansas City Automobile Dealers' Association.

#### Reviews of Specifications. 928,800. Roller Bearing.—August Schilling, of Berlin, Germany. July 20, 1909.

In this bearing the rollers, instead of being either cylindrical or conical, as in the majority of roller bearings, have curved generatrices. The bearing in general is similar to an annular ball bearing, with rollers substituted for balls. The races have curved annular projections of a

smaller radius of curvature than the rollers, so that the latter bear only at a single point, theoretically. The object of this arrangement is to reduce the friction coefficient. In order to be able to fill the bearing completely full of rollers, one or more of the rollers are provided with flats, these being inserted last. The rollers are held in the proper relative positions circumferentially by means of cages, as shown in the illustration.

**NUMBER 16** 

#### Larger versus Smaller Tires.

BY JAMES S. MADISON.

The car that has been under daily observation for the past eighteen months is a chain driven, 14-16 horse power runabout, with a two cylinder opposed motor under the seat. The wheels are of the usual artillery type, each wheel having twelve spokes. The size is 30x31/2 inches. With the two passengers who usually ride in it the car weighs 2,300 pounds. It was originally equipped with 30x31/2 inch q. d. tires. The weight supported by each wheel was far in excess of that recommneded by the tire manufacturers. This was a mistake, for which the car manufacturer and not the owner was responsible, unless it be claimed that the owner before purchasing the car should have been sufficiently informed as to specify larger tires. But this would involve the assumption that each prospective purchaser should acquire definite information about the thousand and one details of the making and handling of an automobile before he becomes an owner. This would be desirable for many reasons, but clearly it is impracticable. The new owner must accept much on faith.

In the case in question the tires were overloaded, and could not be expected to give the service for which they were intended. They began to show the effects of the excessive load they were carrying before they had made 1,000 miles; at 1,500 they began to develop sand blisters and suffer a great many cuts from stones and other sharp objects. Soon after this it was a rare occurrence to take the car out for even a short run of to to 20 miles without discovering several bad cuts or blisters on the return. By changing the rear tires to the front wheels, and by the most careful and persistent attention, including scores of vulcanizations, a mileage of 2,400 was obtained from the set when it was discarded. It would have been wiser for many reasons, and truer economy in the end, to have ceased paying any attention to them after the 1,500 mile mark had been passed. This would have saved much time and annoyance. In addition to the excessive weight the tires were carrying, another factor, of secondary importance, which led to their rapid deterioration, was the ignorance of the owner as to the proper method of handling his car in order to save the tiressudden stopping and starting, too frequent and sudden use of the brakes, too great a speed in turning corners, etc.

When the time came to get a new set of tires there was the choice between 30x4 inches and 31x4 inches. In order to make assurance doubly sure, the latter, the so called odd size made to fit a 30x31/2 inch wheel, were selected. This change of casing involved a change of the inner tubes. The new outfit consisted of four casings and five inner tubes, which would cost at the

present prices \$238.65.

The new tires have been under careful observation for six months; they have been driven 3,000 miles. The wear is scarcely perceptible. Their appearance at present would indicate that they will easily give 5,000 or more miles of service. There has been but one puncture; that was caused by a sharp pointed 4 inch logbolt that would have penetrated an inch plank under favorable conditions. One of the reasons for freedom from punctures is largely due to the unusual thickness of the rubber in the tread; the manufacturers claim that this type of tire contains 15 per cent. more rubber than the usual type, in consequence of which the tread is thicker. A number of tacks, pieces of wire and small nails have been removed from the tread that would have caused punctures in the smaller tires.

The effects of the larger tires on the car have been very definite and pro-

#### THE DISADVANTAGES.

The new tires have made the car more sluggish on the hills, and necessitate going into a lower gear earlier and oftener. The owner who equips with the larger tires will find that he is unable to take the same hills on high gear that he formerly did.

The most unpleasant development of the change is the much greater tendency of the car to slip and skid on wet pavements and roads. Shortly after the new tires were on the owner attempted to go up a hill that had been sprinkled with water, on high gear. The car began to slip and turned directly around in the road with the steering wheels at right angles to the direction the car was going. He had gone up that same hill under the same conditions of wetness hundreds of times on high gear without perceptible slipping. Since that first experience he has tried the experiment on the same hill many times; the result is always the

same-there is an unpleasant and even dangerous amount of slipping. He has found it necessary to go into low gear on that hill whenever it is wet. If the road is more than usually muddy or "greasy" from unintelligent or too frequent sprinkling, it is somewhat difficult to make it, even on low gear-not from lack of power as the power is ample, but because of the slipping and skidding.

It is somewhat difficult to arrive at a satisfactory explanation of the slipping. It is not certain that the presumably larger surface of contact between the casings and the road is the cause. While no measurements of the surface of contact of the smaller and larger casings have been made. it should be taken into consideration that the larger ones probably present a smaller surface, in view of the fact that the casings under the load are more curved in spite of the larger dimensions in the new than in the old, due to their being inflated to a higher degree. The smaller tires were inflated to 60 pounds pressure; the larger ones are inflated to 80 pounds (determined in each case by the same gauge). This pressure of 80 pounds is advised by the tire manufacturer and is always maintained.

#### ADVANTAGES.

The most noticeable and most important advantage is a greater liveliness of the car on level stretches. The same position of spark and throttle levers, which formerly drove the car 12-13 miles per hour, now gives it a speed of 15-16 miles; these particular positions are: the spark advanced as far as possible, and the throttle closed as far as possible. These are, fortunately, the most economical positions for the car in

A second advantage is a greater comfort in riding. Many of the small road shocks which were formerly noticed are now absorbed by the tires. This means less work for the springs and less vibration to the

The third advantage is that, notwithstanding the much greater initial cost, there is a very substantial economy if the calculation be made by dividing the cost of the tires by the total mileage obtained. The smaller set cost \$160, making the cost per mile 63/3 cents. Assuming that the larger set will give a mileage of 5,000, the cost per mile will be 434 cents.

The larger tires has been so satisfactory that there never will be any question in the writer's mind of going back to the smaller

#### Rendering Cars More Quiet.

By Albert L. Clough.

It should not be forgotten that the enclosing of the various elements of a motor car serves another very useful purpose besides guarding the parts from the weather and from the intrusion of dirt and dust and of localizing the supply of lubricant. The surrounding of moving parts by tight housings or cases confines and deadens the noises made by the parts thus enclosed. The hood which covers the motor, the covers which protect the valve action on some cars, the casings which surround the engine gears, the cases which house the gear set and the final drive all serve this purpose in addition to their primary functions. The same thing may be said of the pan which underlies the entire mechanism and the car body which overlies it.

#### STRIPPED CAR SHOWS DIFFERENCE.

Anyone who has noticed the noise made by a stripped car being tested out with the engine hood and body removed and the pan perhaps discarded, as compared with the sound made by the same car in normal operation, will realize how important is the quieting effect of enclosing working parts.

It is safe to say that if all noise producing parts of a car were completely enclosed by perfectly non-sonorous housings no noise would be transmitted to the surrounding air and the car would operate in perfect silence. All the energy possessed by the sound waves set up by the working parts would be frittered away as heat within the housings, and none would be conducted by these housings to the outer air.

In practice, however, it is impossible to realize these conditions in two respects, for it is impracticable to absolutely enclose all parts, and it is not feasible to employ absolutely non-sonorous materials for the housings. The engine housing or bonnet (at least in the accepted type of construction) must be more or less open for the ingress of cooling air, and the rear end of the underpan is generally not closed in about the under side of the body, because the air current must have exit. The mechanism is thus not fully housed.

#### ALL METALS RESONANT.

Metals are the most available materials for the construction of housings, and metals are all more or less resonant. Sheet steel, the most commonly employed material, is highly resonant, and aluminum is quite sonorous. The sonorous property seems to be roughly related to the elastic qualities of materials and to the homegeneity of their fibrous texture. Such materials as leather, paper and fabrics are almost non-sonorous. Thin sheets of sonorous materials are especially prone to transmit noises to the outside air when used as housings, and this

is the reason why sheet steel hoods and underpans are no more effective "sound proofers."

The writer was prompted by curiosity to try the following experiment: A car, in first class running order, was operated at constant speed over a level road, and, at intervals, a heavy carriage robe was placed over and taken off from the tight metal hood. It was easy for a person in the tonneau, with his eves closed, to tell when the robe was put in place and when it was removed, by the increase of noise due to its being taken off. The difference was specially noticeable when the car was being run on the low and middle gears, the valve action being more noticeable under these conditions than when third speed was engaged.

#### TRIALS WITH A ROBE.

This was undoubtedly an instance of the taking up of noise vibrations by the metal of the hood and their transmission to the external air. The robe, in great measure, absorbed the vibrations which would otherwise have been communicated to the air. One of the leading manufacturers is said recently to have adopted soft sheet copper as a substitute for sheet steel for his hoods, copper being much less sonorous than steel. It would be interesting to know whether any manufacturer has experimented with a metal hood lined with vulcanized fibre. This material is noticeably non-sonorous, as witness its employment for phonograph horns, where the object to be attained is to direct the sound, and the object to be avoided is the addition to the reproduced speech or music of any characteristic tone due to the vibration of the horn itsèlf.

It is not at all apparent why vulcanized fibre should not prove an available material for light housings, which are desired to possess non-sonorous properties; such housings, for instance, as those enclosing valve push rods and engine and auxiliary gears. A proper quality of vulcanized fibre can be molded into quite intricate shapes, is readily worked, is light, is not adversely affected by oil and is a very rugged material. While it swells when subjected to moisture it can be treated so as to prevent this.

The tight metal hood is a great improvement over the hood with side openings, which was common a few years ago, as it confines the sound much more closely. The use of sound deadening material, such as rawhide or rubber, between the edges of the hood and its supports may assist in making it less sonorous as well as fulfilling its primary purpose of preventing rattling.

#### THROUGH THE RADIATOR.

A very large proportion of the noise which escapes from the engine to the outer

air passes through the radiator. This is very noticeable to a person who walks around a car which is standing with the engine idling. The experiment was tried of stationing a person at some distance directly in front of a car with his back turned toward the same. He could tell instantly when a carriage robe was thrown over the radiator front and when it was removed, the noise being very slight indeed under the former circumstances, and very considerable under the latter. It is quite noticeable that the motors of air cooled cars, which have only a light screen in the place of the radiator, are decidedly noisy when approaching one

Another thing which must have frequently been noticed is the silent running qualities of cars fitted with hoods of the Renault type, and with the radiator mounted between the engine and the dash. The hood being practically closed, there is but little escape of engine noise toward the front, which is one of several advantages of this type of construction.

Anyone who takes the trouble to lean under the rear end of a car, with the motor idling, and to place his ear near the rear opened end of the pan, is likely to be surprised at the volume of engine noise which issues therefrom. When first or second gear is engaged, and the car is running, the effect may be expected to be even more marked. Closing the pan together at its rear end as much as possible and still leaving room for the escape of the cooling air would seem to be advisable.

It may be stated as an opinion that with the accepted type of radiator arrangement the front end of a car is essentially its noisiest "point of view," so to speak. With a properly devised hood and pan the noises emanating from the sides may be very well muffled. The rear end is likely to be the essentially next noisiest "viewpoint."

SOLID CAST WEB CONSTRUCTION.

Speaking of the underprotection, the use of a solid cast web construction for the pan is probably more conducive to quietness of operation than the employment of a sheet metal construction for this purpose. Sheet steel is resonant in a "drum-like" way, and transmits sounds with facility, while the heavier construction is much less liable to do so. As a rattle producing device the sheet iron underpan is all that can be desired.

So insistent is the demand for quietness of operation that manufacturers are justified in using every means to attain it. The problem is twofold: first, to minimize the noise developed, and, second, to confine, as far as possible, the noise which is unavoidably produced. A vast deal of attention has been paid to the first, but rather less to the second, and there is opportunity for some improvement in this direction.

The use of non-sonorous housings wherever applicable, the introduction of lagged or lined non-resonant hoods, and the fitting of closer and more substantial underpans are suggested.

#### Automobiles in Egypt.

Previous to 1907 the customs department included the spare parts with the importation of the cars, but in that year the classification was divided into two categories (1) complete cars and (2) detached parts. The following statement shows the imports into Egypt of motor cars and detached parts during the years 1907 and 1908:

While the statistics plainly show the hold which French cars have on the Egyptian market, the actual figures are somewhat misleading, for we are given to understand on good authority that a number of cars credited to England are really of French origin, but shipped from England. The French makers were the first, in the field

		-Moto	Detached Parts.			
	—-I	907		908.—	1907.	1908.

		7777				7-1
Totals	250	\$586,280	107	\$245,340	\$48,776	\$18,195

Apart from the point that people here cannot at the present time afford to run cars as they could a couple of years ago, it must be remembered that Egypt is not by any means a "motorist's paradise." Roads up and down the country on which a motor can be used are unknown, and, therefore, apart from Cairo and Alexandria with their respective suburbs, no trade can, under existing conditions, be done with the provinces.

Cairo is far better off for length of roads than Alexandria, for there the motorist can travel from Heliopolis out to the Pyramids, a distance of about 18 miles. The old overland route from Cairo to Suez can also be used to some extent. In Alexandria the motorist is confined to a run to San Stefano, 10 miles. Additional roads, however, are now being constructed both in Cairo and Alexandria, which will somewhat improve matters in this respect.

#### KINDS OF MOTOR CARS IN USE.

Despite the absence of facilities for making long journeys, the demand' in the past, generally speaking, has been for large cars of high power and fitted up in the most luxurious fashion. Seeing that hills of any kind or size are conspicuous by their absence, and that the distances to be traveled are so limited, it seems absurd for a man to have a 40 to 60 horse power car for ordinary purposes, unless he makes use of it for touring in Europe. It has, to some extent, been a case of social rivalry, pure and simple, without much regard to utility. There is no doubt that at the present moment many motorists are regretting that they did not consider the latter qualification rather than the former when they made their purchases, for there are many cars in the garages today which have been standing idle for months and months owing to the inability of the owners to pay the charges for running them. When the present financial troubles are over and money is again earned rapidly, the lessons of the past, so far as cars are concerned, will be forgotten, and the demand once more will be for expensive automobiles.

here, and they have reaped the benefit of their enterprise.

The general manager of one of the largest motor car concerns in the country recently informed the writer that there was an opening for British cars, and that he had been trying, unsuccessfully, to find a good English firm which would be willing to ship a car out on what he termed reasonable conditions, such as, for example, 50 per cent. of the purchase money down, and the balance when a sale was effected.

#### GARAGES, CAR PRICES AND TRADE OUTLOOK.

In addition to sundry small repair shops, there are two well fitted garages in Cairo and one in Alexandria, where repairs can be made. The charges for garaging are about \$12.50 a month for a car not exceeding 10 horse power, and \$17.50 for the larger ones. These charges include washing, cleaning and storage. Petrol is supplied at the rate of \$2.40 per 36 liters (about 27 cents per gallon).

Tires do not wear as well out here as they do in England, the principal reason being the soft, gritty nature of the roads and climatic conditions. The prices of tires run about 18 per cent. to 20 per cent. above quotations in England.

As a rough indication of the prices at which cars are sold in Egypt, cost, freight and duty paid, the following classifications are given: The rich man's landaulet and other similar cars, including harem cars, \$3,890 to \$5,840; the second category, from \$2,920 to \$3,890; the professional man's car from \$975 to \$1,950.

As far as we can gather the motor trade in Egypt is beginning to brighten a little, and cars are now being sold again. For the moment, the Europeans appear to be the buyers rather than the rich young natives, and it is interesting to note that the professional classes are inclined to purchase cars for use in connection with their work; for example, out of five recent sales we understand that three of them were for doctors.

The motor omnibuses and wagons in Alexandria do not appear to have been a

success, for none of them are now at work. The Alexandria municipality has recently granted permission to three separate firms to each put fifty motor taxicabs on the streets. A fourth firm has sent in an application for the same privilege. The first taxicab plied for hire on July 14, and three more have since been added.

#### MOTOR CAR REGULATIONS.

Except in the case of private electric cars, which are entirely exempted, all automobiles in Alexandria and Cairo must be registered and numbered. The following figures relate to the regulations in force in June, 1909: Alexandria, 181 private cars, 28 motor omnibuses, 16 motor wagons and no motor cabs; Cairo, 501 private cars, 28 motor omnibuses, 5 motor wagons and 38 taxicabs, of which 5 were electrically driven.

For Cairo and suburbs the speed limit for automobiles of any description is 15 kilometers (9.3 miles) per hour. In Alexandria the limit for private cars is 15 kilometers, but in the suburbs there is no fixed limit for private cars, but one of 15 kilometers for other vehicles.—From Bulletin of British Chamber of Commerce for Egypt.

#### Imports and Exports for August.

The imports of automobiles continue to show a slight increase. During the month of August there were imported 194 cars valued at \$333,960 and parts valued at \$114,-973, as compared with 179 cars valued at \$280,070 and parts valued at \$40,676 in August, 1908. The heavy increase in the importation of parts is particularly noticeable. Of the 194 cars imported last August, 109 were from France, 52 from Italy, 9 from Germany, 8 from the United Kingdom and 16 from other countries. During the eight months ending with August, 1909, there were imported 1,058 automobiles valued at \$1,926,603 and parts valued at \$575,971, as compared with 737 cars valued at \$1,451,-594 and parts valued at \$348,431 during the same period the previous year.

During the month of August last there were exported 360 automobiles valued at \$557,934 and parts valued at \$100,622, a total of \$658,556, as compared with 156 cars valued at \$346,796 and parts valued at \$44,-074, a total of \$390,870 during the same period the previous year. It will be observed that the exports of both complete cars and parts show a heavy increase. During the eight months ending with August, 1909, there were exported 2,140 cars valued at \$5,107,953 and parts valued at \$526,492, a total of \$5,634,445, as compared with 1,684 cars valued at \$3,569,962 and parts valued at \$434,849, a total of \$4,004,811 during the same period the previous year. Perhaps the most remarkable thing in connection with these statistics is the high average value of the exported cars, about \$2,500, which is considerably higher than the average value of the imported cars, which figures out to less than \$1,900.

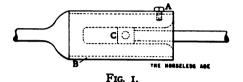

# Maintenance and Repairs

### Repairs and Difficulties. By H. S. Wheeler.

SUBSTITUTE FOR A SET SCREW.

Once when at the bottom of a steep hill the clutch was dropped in but the car did not pick up speed. Upon investigation it was found that set screw A (see Fig. 1), holding the casing of the universal joint

between the clutch and transmission, had dropped out. The casing or sleeve B had worked ahead so that the square blocks C had dropped out into the sod pan. 'The set screw was gone, and the question was "How shall we get home?"

The joint was reassembled and a piece of wood requisitioned from a fence rail. This was whittled into a plug, driven into the set screw hole, turned a half turn in the hole with the pliers (so the wood entered the thread) and was wired in. The car got in with this repair, as obviously there is very little strain on the set screw holding the universal sleeve in place.

A permanent repair was made by fitting a new set screw, drilling the head and passing a wire through it and around the sleeve.

#### QUIETING TIMING GEARS.

The timing gears in a car of an obsolete model became noisy, as timing gears will, and the problem was to quiet them. It was done as illustrated in Fig. 2A. Some very thin sheet copper was secured and cut to the same width as the idler gear face. This was fitted carefully over the teeth and fastened in several places, as at A in Fig. 2B.

A little depression was filed at the root of a tooth B, the two ends (or single thicknesses) were pressed into place in the depression, and a soft iron wire passed

over the ends and fastened completed the repair. The thickness of copper used is determined by the amount of back lash and clearance in the gears.

#### REPAIRING A CRACKED CYLINDER.

One day a car came in with the front cylinder casting cracked at the fan stud.

The fan stud was removed and the shoulder turned down a bit, and a patch was fitted over the crack and around the hole where the stud was screwed in. Care was taken to see that the shoulder of the stud had a good bearing on the patch. The stud was then tightly screwed down in place, with the patch over the crack, and the whole was brazed together, thus making a permanent repair.

Originally the stud had a taper thread, so screwing it up against the shoulder prevented the stud from being screwed in further by the pull of the fan belt and forcing the crack in the jacket open.

#### A MAKESHIFT COMMUTATOR SPRING.

An old "one lunger" with cam commutator got into trouble one day. The flat commutator spring A broke on the road. To get home a new spring (?) was made with hammer and cold chisel from a convenient tomato can, using a piece of steel wire bent as at B for a spring.

Once a cylinder head gasket blew out "40 miles from nowhere" (and no interurban). Of course, no packing was at hand, but after a little thought a gasket

that made the return trip possible was fashioned from a piece of rubber matting from one of the running boards.

STARTING ACETYLENE GENERATOR IN COLD

#### WEATHER.

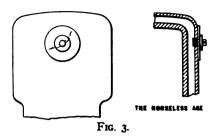

Alcohol in water will lower the freezing temperature of the mixture, but too much alcohol in the water of an acetylene generator will give a yellow flame of little penetrating power. Usually the heat generated by the action of the water on the carbide will keep the water from freezing, but the question is to start the generator when the water is frozen.

To do this make a torch of a piece of waste saturated with gasoline and tied to the head of a hammer. This will start the ice melting. If you still have trouble put a small piece of carbide into the water tank of the generator. After this has been done it will often be necessary to remove the generator wick for cleaning.

#### MISCELLANEOUS HINTS.

A novice once took his first long trip alone in a "cone clutch" car. Being a novice he kept his foot upon the clutch pedal, causing the clutch to slip and the leather to burn so that it would not hold. Upon getting the garage by 'phone the use of dust applied to the clutch surface was explained, and he was also told to drive some toothpicks under the leather at various points around the clutch circumference. The parting injunction was to "keep your foot off the pedal, except when you want to throw out the clutch."

"For lack of a nail," etc., applies equally well to horse and a motor car. A good many cars have come home successfully with a driving chain or a pump chain repaired (when the side links were not broken) with rivets made from a nail removed from a fence board and riveted over

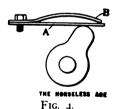

with a stone for an anvil, and in the case of one careless man with a stone for a hammer.

A good many men come in with a tire flat and absolutely ruined because "I couldn't get it off the rim." If the driver had tried running the car carefully for, say, a hundred yards, he would have found that it no longer stuck to the rim and was easily removable.

### New Indiana Manufacturing Concern.

The Indiana Motor and Manufacturing Company has been organized in Indianapolis, and while the general offices will be in that city the factory will be located at Franklin, where the former plant of the American Harness and Leather Company has been purchased. A 35 horse power, five passenger touring car will be made, and will be placed on the market about January I. Officers and directors of the

company are: John C. Billheimer, Indiana Auditor of State, president; Donald J. Hayden, secretary; Charles B. Riley, general manager, and John E. Matson, superintendent and engineer; R. A. Lemcke, Charles A. Denby and W. F. Crawford. The vice president and treasurer is to be elected later. The company has an authorized capitalization of \$100,000.

#### Indiana Registrations.

There were 5.652 motor registrations made with the Indiana Secretary of State between January 1 and October 15, making a total of 14,270 registrations since the law became effective. Of those registering so far this year, about 600 have been owners of motorcycles. The record is much better than that made last year, and it is believed the 1909 registrations will exceed the 6,000 mark.

#### Next Season's Output.

There appears to be a tendency just at the present time to estimate the number of cars which will be produced next season on the basis of rumors rather than from what previous experience and common sense would tell us. Upon every hand new companies are starting up. Every one of them is reported to be planning to build from 2,000 to 10,000 cars, and if we add these reported thousands together the aggregate is enormous.

A glance backward over the history of automobile promotion for the past few years will show us, however, that only about 10 per cent. of the companies started ever build more than a dozen cars; more than half of them probably never get farther than the production of a model, while many quietly pass out of existence even before the model is completed.

To successfully start a new company four things are essential, namely, sufficient capital, ability to use the money to good advantage, good designing talent, and good producing talent. The combination of the last three is what most new companies lack, and if either of them is missing failure is at least probable.

Of course some of the new companies will prove very prominent factors in the industry. But even of those which start with all the above requisites for success very few will make over a thousand cars the coming season, unless possibly for very late delivery. Not for lack of capital and ability, but because the thing is physically an impossibility, unless the company has a very early start.

Why is it impossible? The best answer is found in the remark a prominent engineer made to us a couple of years ago: "It only takes a very small part to hang up a lot of cars." Lack of a single casting or forging may often mean a long delay.

In the production of an automobile the first step is to perfect the design. This takes considerable time, for a car cannot be successfully made in quantities until every part is exactly right, and there are certain phases of the designing process which cannot be hurried, no matter how much money or experience is available.

Once the design is completed there remains the far more difficult and time consuming process of completing the organization for its manufacture. The making of wood patterns, metal patterns, dies, jigs and fixtures takes months of time, and they must all be completed before rapid production is possible. The greater the output is going to be the more elaborate the equipment required, and the longer it takes to get, it in usable shape.

If the car is to be manufactured by its producer all this work is centred in one shop, with the additional problem of getting the required machinery in time. If it is to be an assembled car the problem is to get reliable, established manufacturers to make the parts, and this must be done in competition with orders from old customers, who are usually given the preference. Foundries and forge shops are now crowded, and it takes some little time to find out just how much faith can be put in their promises and to run the manufacturing schedule accordingly.

For the past few seasons we have watched the best producers of the industry struggle with such problems, and as a result we have little faith in the large outputs promised by most of the newcomers. Some of them will no doubt do wonderfully good work and accomplish all that may be done in the way of rapid starting. But the majority will find that they are face to face with an unexpectedly complicated problem which only actual experience can solve. Conditions today are not like those of a year ago, and every month adds to the difficulty of starting for those who do not know every step of the way.

#### America Now Exports Quality Cars.

Three or four years ago the United States imported automobiles of the most expensive class and exported cars of the cheapest class, mostly runabouts. The average declared value of the imported cars for several years ranged in the neighborhood of \$3,500, while the average value of the exported cars was \$1,550 during the last six months of 1906, when the number of exported cars first began to be stated in the import and export statistics. During the past two years the valuation of the imported cars has constantly decreased, while that of the exported cars has constantly increased, until the returns for the first eight months of the current year show the average value of the exported cars to considerably exceed that of the imported ones.

The rapid growth of our export trade shown by this latest report is extremely gratifying. Taken in connection with the rise in average value it shows that American cars of quality are beginning to be appreciated abroad. The decline in the valuations of the imported cars shows, moreover, that American buyers of the highest grade of cars have come to recognize the fact that it is no longer necessary to go outside the country to meet their requirements, thus confirming the view evidently held by a goodly number of foreign purchasers with respect to American quality cars. There is, however, another possible interpretation of the decline in valuation of foreign cars. In Europe the tendency of late has been entirely away from big. high powered cars, and the manufacturers are featuring and pushing their small cars, or town cars. This holds good of manufacturers of the highest grade cars as well as of those who cannot lay claim to this distinction for their product, and the result has been that aside from taxicabs the automobiles imported during the past year have been for the most part of the lighter

and smaller class, very moderately powered.

With the aggregate valuation of our auto exports for the first eight months of the year exceeding \$5,000,000, we stand a good chance of regaining second place as an auto exporting nation, which was wrested from us by Italy last year. It might have been expected that the en masse production of low priced "Thirties" and "Twenties" in this country during the past year would have led to heavy exports of these types. That but few of these cars seem to have been sent abroad so far may be explained by the fact that the home market for them has been so large that it could not be supplied, and by the further fact that the creation of most of these types is of too recent date for them to seriously influence the export returns.

#### Double Spark Ignition.

In answer to an inquiry in a recent issue we stated that we did not believe that the production of two simultaneous sparks in a motor cylinder would appreciably affect the output of the motor. In making this statement we had reference, of course, to the maximum output of the motor, when the mixture is adjusted to give the most powerful explosion. Such a mixture is very quick burning, as has been proven by very carefully conducted tests. It is also proved by manograph cards taken under such conditions. On an engine diagram taken at full load with the ignition properly timed, the curve upon explosion rises almost vertically, and then drops sharply, thus showing that the entire volume of the gas is ignited almost instantly. If the charge became ignited gradually the curve would rise gradually. This is what it does when the charge is overrich and consequently burns slowly, or when it is too lean. A mixture too lean in gasoline will often continue to burn all through the power and exhaust strokes, and then ignite the new charge as soon as the inlet valve is opened, causing a carburetor explosion.

A mixture which is either too rich or too poor in gasoline can, of course, be burned more rapidly by igniting it at two points at the same time, but in the case of a properly dosed mixture there is no advantage in two simultaneous sparks. The object of the driver should, of course, always be to so adjust the carburetor as to give a substantially perfect mixture, as this will not only insure the maximum power but also will tend to the economizing of the fuel.

#### Fall Touring.

Midsummer is generally regarded as the ideal touring period, and no doubt most of the longer tours are made at that time of year, for one reason because it is the conventional vacation period. But there are those who prefer to make an extended auto trip during the autumn, and there are a number of reasons for their preference. In the first place heavy storms which might interfere with a tour are extremely rare in October and November. Then there are those who tour to enjoy the beauties of nature, and who consider nature at her loveliest when the foliage is turning in color. Finally, many motorists are impelled to make good use of their cars during these months by the reflection that long, weary months are coming, during which there will be little if any chance for pleasure trips in their cars. It is no doubt this latter consideration to a large extent which accounts for the heavy auto pleasure traffic observed in the vicinity of New York on recent Sundays,

The roads are probably less dusty on the whole at this time of the year, owing to the heavy dews and night frosts, than in midsummer, and the enjoyment of scenery and the benefits to health from touring are as much within the reach of motorists now as earlier in the season.

#### Atlantawards.

During the next several weeks events in the automobile world will largely centre around Atlanta, Ga., which aspires to become the Southern distributing centre of the motor car industry. On October 25 a tour will start from New York, headed for the Southern city, which, from present outlooks, will combine more participants than any competitive event of the season. On November 6 the first national automobile show will be opened in Atlanta, and while it will probably not be quite as large as some of the other national shows, especially in respect to accessories, yet no less than sixty car manufacturers have taken space. including most of the older and best known firms, and the show will certainly surpass anything ever seen in this country outside New York, Chicago and Boston. Simultaneously with the show there will be held a series of inaugural events on the new Atlanta motor track, which has been carried to completion in record time.

That the South, and particularly Atlanta, is rapidly gaining in importance as an auto market has been apparent in various ways

of late. Many new agencies have been established there recently; some of the prominent manufacturers have located factory branches there from which they will handle their business in the South Atlantic States, and there has been much activity in garage building in Atlanta recently. The influence of Southern conditions is also apparent in the option given this season by a number of manufacturers on a 60 inch tread. This is the standard width of wagon tracks in the South, and as the roads in that section of the country are in general quite rutty, it is important that cars should "track" with the horse vehicles.

There is little doubt that the chief event of the coming month, the Atlanta Show, will be a thorough success. The show has certainly been effectively advertised by the local press, which, in addition to the New York-Atlanta Tour, is organizing a series of runs to Atlanta from the different towns in the State, and conducting in connection therewith a forceful good roads campaign. The novelty of an automobile show, especially a national show, bids fair to be a strong attraction, and the simultaneous running of races on the newly built speedway should aid in drawing crowds; for, aside from the Florida Beach events and the two road races held at Savannah, automobile racing is more or less a novelty in the South Atlantic States.

#### Coming Events.

October 16-23—San Francisco, Cal., Automobile Show, Emporium Building, Automobile Traffic Association.

October 18-30-Dallas, Tex., Show at State Fair.

October 21-Waterloo, Neb., Race Meet, Waterloo A. A.

October 21-22—Boston, Mass., Reliability Run, Bay State A. A.

October 22—Hartford, Conn., Sociability Contest A. C. of Hartford.

October 22-29—San Antonio, Cal., Reliability Contest, San Antonio Light and Gazette. October 23—Atlanta, Ga., opening of Atlanta

Automobile Track.

October 23—San Francisco, Cal., Road Races, A. C. of California.

October 24-28—Houston, Tex., Five Hundred Mile Endurance Run for Houston Post Trophy.

October 25 to November 3—National Tour, from New York to Atlanta, Ga.

October 27-29—Vicksburg, Miss., Race Meet, Vicksburg A. C.

October 28-30-Dallas, Tex., Race Meet, State Fair.

October 30-Vanderbilt Cup Race, Long Island Motor Parkway, Long Island, N. Y.

October 30-31—Los Angeles, Cal., Inaugural Meet at Ascot Park, Los Angeles Motor Racing Association.

November 1—Indianapolia, Ind., Race Meet, Indianapolis Motor Speedway Co.

November 3-13—Salt Lake City, Utah, Outdoor

November 6-Start of Los Angeles (Cal. Phœnix (Ariz.) Road Race, Maricopa A. C.

#### Carburetor Experiments.

By H. L. HEPBURN.

In my article on "Carburetor Principles" in The Horseless Age of April 14 I proved that whatever might prove to be the law of porportion of gasoline and air to form an explosive mixture under varying conditions, the fixed loss of head of the gasoline jet was sufficient to account for the unsatisfactory results obtained, even supposing the proper proportions of gasoline and air to be constant, whatever the intensity of the engine suction or the compression.

If this fixed loss of head could in some manner be eliminated, and the proper pro-

Fig. 1.

portions of air and gasoline proved to be constant, we would evidently have the perfect carburetor without any valves or springs of any kind, but a free and clear passage both for the air and the gasoline. It should, perhaps, be stated right here that I am talking of the carburetor as a measuring machine without any reference to its action as a vaporizer, as I do not believe it is possible to combine these two functions.

Taking the same two opposed cylinder car, as mentioned in my previous article, I fitted it with a carburetor of well known make, and also connected the top of the float pit of the carburetor to the crank pit of the engine with a one-quarter inch pipe in which were a ball check valve and a needle valve, the ball check being near the crank pit and the needle valve at the float pit. By this means I was able to apply a pressure to the surface of the gasoline in the float pit from the compression in the crank pit, and, moreover, I was able, by means of the needle valve, to regulate this pressure as required. Also, the body of the pipe, lying between the check and needle, acted as a receiver and at a given speed of the engine allowed me to maintain practically a constant pressure in the float pit during the stroke. Again, the rise of pressure of the air in the crank pit was so small and the total amount of air discharged into the float pit so small, in comparison with the displacement of the pistons, that the air pressure in the float pit was practically a constant, no matter what the speed of the engine was.

The carburetor was so mounted that the air entered the top and left through the side opening. The valve cage was removed entirely, and the engine was started. It was found perfectly possible, by means of the regular gasoline needle and the air needle valve, to feed the engine a perfect mixture for both wide open and nearly closed throttle positions while idling, but on wide open throttle a large portion of the gasoline issued from the jet and traveled

clean through the column of air, wetting the intake pipe on the outside with a perfect spray of gasoline. So much for the vaporizing tendencies of this carburetor.

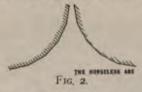

I next soldered an elbow on the cover in such a manner that this stream of gasoline was bound to strike and spread out over its inside surface. The engine could now be fed a perfect mixture while idling on both open and nearly closed throttle, and showed considerable speed, but on a hill which staggered the car the engine would go out entirely below some certain speed, but would catch again and climb the hill at a much lower speed. I scratched my head a long time and finally decided that the gasoline jet was at fault.

#### CHANGED NOZZLES.

The construction giving me somewhat the results of Mr. Tice's nozzle A (see THE Horseless Age of June 19, 1907), I, therefore, decided to remove the offending needle, reducing at the same time the nozzle mouth. This improved matters considerably, but there was still a point of weakness at medium shafts. Next I enlarged the nozzle mouth and introduced the needle down into it, on the supposition that I would get nozzle E of Mr. Tice's article, but very little improvement was noted. Maintaining the needle in this new position, but making it a very long taper, I now tried in succession (1) a nozzle with a tapered entrance, (2) a tapered nozzle, (3) a nozzle with a succession of tapers, as shown in Fig. 2, and (4) a rounded entrance.

These nozzles were successively improvements, but perfect results were not attained on my car until a nozzle was made which was one-sixteenth inch at the mouth, 2 inches at the entrance, and was formed as shown in Fig. 3.

My own idea of the cause of this is that the change of direction of flow of the gasoline particles is so slow that the loss of head, due to any tendency of the stream to

contract, is obviated, and the loss due to friction is reduced to a minimum.

With this shaped nozzle the body of the standard carburetor was abandoned and a special carburetor used in which the nozzle stands vertically in the centre of the float pit, and the air passage dips down into the float pit to, but not below, the gasoline level. The air pressure pipe is dispensed with.

At any rate, my car will now take at a speed of, say, 8 miles per hour, any long hill which it will take under any conditions of speed, and while the car possesses more speed than ever before, I can throttle it

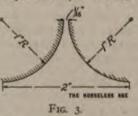

down to run less than 3 miles per hour on the high speed.

Under these latter conditions the 11/4 inch free intake is throttled down (at the throttle only) to the equivalent of a one-eighth inch circle.

In fact, I think so well of the construction that I have taken steps to surround it with patents.

VALVE SETTING AND FUEL ECONOMY.

As regards economy, the mileage was increased in this old type car from to miles per gallon to 12 miles per gallon. I cansider the actual results in any individual case will depend more, or at least as much,

on the engine as its does on the carburetor. While on this subject, I noticed in THE HORSELESS AGE, some months ago, some diagrams showing the increase in power and economy with an increased lay of the inlet valve closing, and these effects increased with each increase of speed. However, if "Careful Reader" will take these curves and prolong them to the left of the diagrams he will find that at speeds of approximately 600 r. p. m. these conditions would largely be reversed. As my recollection goes, I believe the lowest speed shown on any of these diagrams was 1,100 r. p. m., and they would be very applicable to a car geared 3 to 1, with 32 inch wheels, the slowest speed of which on the high gear was about 30 miles per hour:

Personally, I believe in a slight lag of the inlet valve closing, but such results as given in the article noted are misleading to the hasty and the novice. The only thing shown absolutely by the curves is that one and the same engine cannot possibly be the most economical engine on the market under all conditions. Moreover, motorists divide readily into two classes, viz., those whose desire is to climb the biggest hill on high gear, and those whose desire is to speed at all costs, and it is perfectly evident from these curves that, neglecting all carburetor and other defects, the same valve setting cannot give the best results for either economy or power under both tests.

The French budget for the coming year is said to contain a provision according to which the owners of foreign motor cars who travel on French highways will be compelled to pay a tax. The tax is to be based on the horse power of the car, and on the length of time the owner expects to stay in the country. It will be remembered that a similar proposal was made in the Chamber of Deputies a number of years ago, but was promptly voted down because it was considered detrimental to the well developed tourist industry of France.

# NEW VEHICLES

## The New Croxton-Keeton . "Suburban."

The new "Suburban" car built by the Croxton-Keeton Motor Company, of Massillon, Ohio, is expected to become their most popular model for 1910. They will continue the manufacture of their German type 45 horse power car. The new French type "Suburban" will be provided with several designs of bodies, viz., four or six passenger touring, landaulet and brougham bodies. The landaulet is recommended by the makers for use as a taxicab, being provided with the driver's seat at the left; the control levers (speed and brake) in the centre, and a trunk rack on the right in place of the other seat. The turning radius of this car is very short, it being possible to turn completely around in a 25 foot circle. The country or suburban models are all equipped with right hand drive with control at the side. It might be stated also that the town cars can be had with a double front seat instead of single seat and trunk rack, if desired.

The motor is four cylinder, four cycle, water cooled, of 41/4 inch bore and 41/4 inch stroke. The cylinders are cast in pairs with the valves all on one side and operated by a single cam shaft. Very spacious water jackets are used, which are increased at the top over the cylinder head, where the heat is the most intense. The pistons are of gray iron, being of the same material as the cylinders; they are quite long, and are provided with four eccentric compression rings. All pistons are ground to size, and the rings are ground on their sides. The connecting rods are drop forged, of 45 point carbon steel. They are of I section, 103/4 inches long, with a phosphor-bronze bearing at

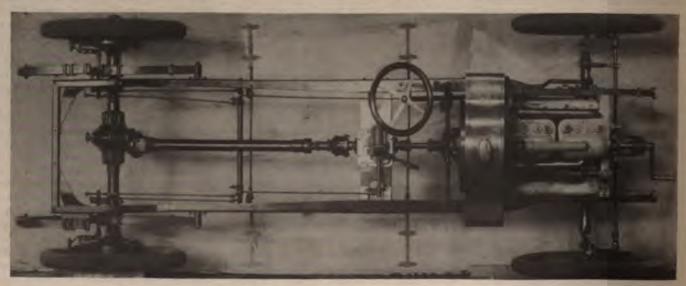

THE CROXTON-KEETON SUBURBAN.

the top, I inch in diameter and 176 inches long. The top of the connecting rod is milled out, making a basin which catches oil for lubricating the piston pin. The lower bearings are die cast of nickel babbitt, 15% inches in diameter and 21/4 inches long. The valves are 134 inches in diameter, with three-eighths of an inch lift, and are interchangeable. The cam shaft is of high carbon steel, 11% inches in diameter, hardened and ground, with three bearings. The cam shaft gear and magneto gears are all housed in an oil tight compartment cast integral with the crank case. The crank shaft is of 45 point carbon steel, hardened and ground, with three main bearings, all 11/4 inches in diameter and the following lengths: Front and centre, 3 inches each; rear, 41/2 inches. The shaft is drop forged and has the flange to which the flywheel is keyed and bolted forged integral with it. The flywheel is of peculiar design, being constructed on the principle of a blower. It takes in air from the right side of the motor and forces it out through the radiator, which is located at the rear of the motor, and over and on either side of it, forming part of the dash. It is claimed

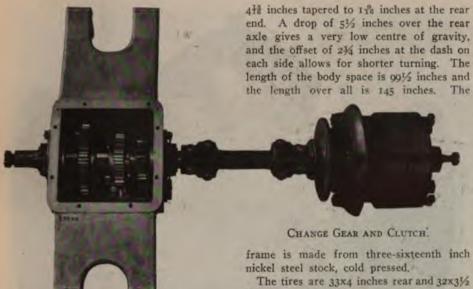

that even though no water pump is used, it is impossible to overheat the motor with this arrangement.

The crank case is in two parts. The lower portion contains two compartments, the lower one being the oil reservoir from which the oil is pumped to the several bearings by a plunger pump, operated by a cam on the cam shaft, and the other compartment forming the splash basins, which are so arranged that the oil level is maintained constant. The top portion of the crank case contains the crank shaft bearings, which are independent of the lower half

The clutch is of the multiple disc type, and is contained in the flywheel. It contains sixty-one discs working in oil. Between the clutch and the change gear is a shaft of nickel steel, the ends of which are squared and fitted into corresponding coupling sleeves. These sleeves connect with the squared ends of the clutch and change gear shafts. The object of these universal joints is to take care of the twisting of the frame over very rough roads, and they also permit of the removal of the clutch without interfering with the motor or gear box. The change gear is of the

PLAN OF CROXTON-KEETON SUBURBAN CHASSIS.

selective sliding type, with the shafts carried on annular ball bearings in an aluminum case. The three speeds forward and reverse are worked through a single lever in an H quadrant. The shafts and gears are of 31/2 per cent. nickel steel and heat treated. Lubrication of the moving parts in the gear box is effected by splash in the casing, which is oil tight. The universal joint immediately to the rear of the gear case is the only universal between the change gear and rear axle. This is a ball type universal and forms the forward support for the torque tube. The propeller shaft is encased in the tube, consequently it is entirely protected from dust and mud, and is carried in New Departure ball bearings at both ends. The driving bevel pinion is keyed to the end of the propeller shaft on a taper bearing, and is held in place by a lock nut and washer.

The differential is of the bevel gear and pinion type, with the casing carried on annular ball bearings. The differential drive gears are keyed on to the ends of the rear wheel drive shafts on taper seats, and are held in place by a lock washer and nut. The rear wheels are keyed to the outer ends of the drive shafts in a similar man-

The rear axle housing and tubes are of liberal size. The axle housing is split in the centre, and a strong truss rod extends underneath the axle from end to end. The front axle is tubular and is dropped 31/2 inches below the centre of the wheel spin-dles. The front wheels are carried on Timken roller bearings. The centre of the

axle is carried forward around the base of the motor to give greater road clearance. The 16 incl steering wheel, with alumi-num spider, tworks through a worm and gear with ball thrust bearings. The worm gear is a full adjustments to new surfaces. The frame, which is especi, ally strong, is of 45% inch channel section. with a maximum width of

Any color desired can be furnished, but blue, with cream gear, and green are the

standard colors.

frame is made from three-sixteenth inch

The tires are 33x4 inches rear and 32x31/2 inches front, and the wheel base is 114 inches. The front wheels have ten spokes and the rear wheels twelve spokes. Quick detachable rims are fitted all around.

The Bosch dual system of ignition is used with combined coil and switch on the dash. The thermo-siphon cooling system is used. There are no spark and throttle levers, as the ignition is fixed, and the engine is controlled by means of an accelerator pedal.

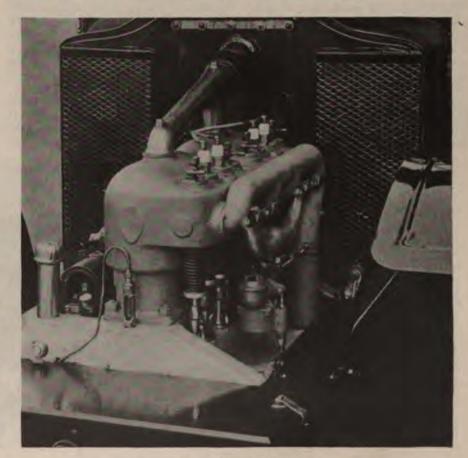

The brake system consists of two internal expanding brakes and two external contracting ones. These all operate on the rear wheel brake drums, which are 14 inches in diameter, with 21/2 inch face. The

internal brakes are the emergency brakes, and are operated by a hand lever at the driver's right hand. The external brakes are the service brakes, and are operated by pedal. Neither set of brakes is interconnected with the clutch, and both sets work through long equalizers.

The springs in front are semi-elliptic, 32 inches long and 134 inches wide. The rear springs are three-quarter scroll elliptic, 43 inches long and 2 inches wide. The front half of the bottom member acts as the radius rod and carries all the driving strains.

#### To Manufacture Axles in Detroit.

The Russel Motor Axle Company has been organized in Detroit, Mich., as a subsidiary to the Russel Wheel and Foundry Company, which recently purchased the plant of the Wagner Machine Tool Company in North Detroit. This plant, which is located on the Bay City division of the Michigan Central Railroad, will be used for the manufacture of automobile axles. They plan to begin operations about December 1. The capital stock of the new organization is \$100,000, and the officers are as follows: A. W. Russel, president; W. S. Russel, vice president, and George B. Russel, secretary and treasurer. The yearly capacity of the plant is given as 10,000 axles, and it is hoped to begin deliveries by the first of the year.

FRONT VIEW OF MOTOR.

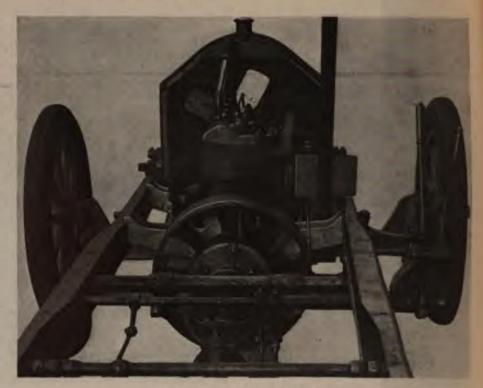

#### The 1910 Model Marion.

Only one type of the Marion car will be built the coming year, which will be known as the Model 10. It will be equipped, at the option of the purchaser, with either a five passenger touring body or a four passenger close coupled body, and the equipment will include a magneto, a Prest-O-Lite tank and a full lamp and tool equipment. In a general way Model 10 will follow closely the lines of Model 9 of the past year. Only changes of minor importance have been made in the construction. Among these may be mentioned the use of the Mercedes type of radiator, giving greater cooling surface; a new design of horizontal steering arm located above and protected from accident by the front axle, and a more roomy body, larger tires, improved springs, and a new and more powerful brake equipment, with all four brakes of the internal expanding type protected from rust and mud; a Fiat type of frame, larger and heavier all around, and narrowed in front to give a short radius in turning; the use of Timken roller bearings, a larger rear axle and an improved multiple disc clutch.

The motor is of the four cylinder, four cycle type, suspended from the main frame, which is especially braced for the purpose. The cylinders are offset from the centre of the crank shaft, and are of 4½ inches bore by 4½ inch stroke, the motor developing 35 horse power at 1,000 r. p. m. Every motor is given four distinct and separate tests for power and smooth running.

The cylinders are cast in pairs, with the valves all on one side. The intake and exhaust being both on one side, the other side of the motor is left free for the water circulating pump and magneto, without crowding either for space.

The crank case is cast in two sections of aluminum alloy. The rotary oil pump, driven by bevel gears from the cam shaft, is housed in the lower section of the crank case, and is so adjusted that the correct

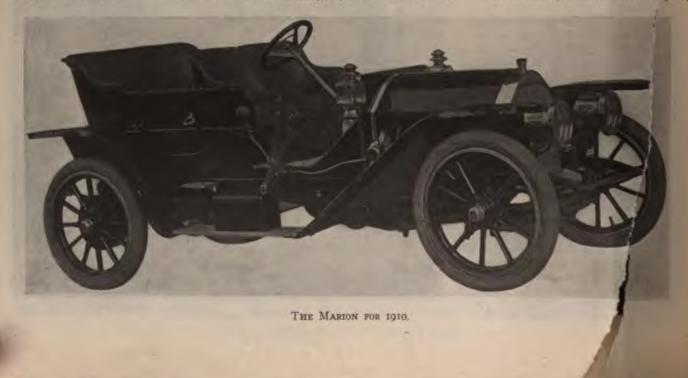

REAR VIEW OF MARION MOTOR.

level of oil is kept in the crank case at all times. The reservoir has a capacity of 2 gallons. A glass sight feed is provided on the left side of the engine through which the quantity of oil flowing may be observed. Timing gears, oiler and other motor parts are reached for repair or adjustment by removal of this lower section of the crank case, which is held in place by castellated nuts. Both the crank case and motor are protected from dust and mud by a sod pan, which extends back beyond the centre of the car.

The crank shaft is drop forged from high carbon steel, hardened and ground. It turns on three white bronze bearings, the latter being easily adjustable for wear. The bearings are of 15% inches diameter, and are tested to insure alignment before assembling.

The valves are of the mushroom type, and are located in the valve chambers of the four cylinders, being operated by the usual arrangement of push rods actuated by the cam shaft. Both inlet and exhaust valves are extra large, thus insuring both a quick and full intake of gas and rapid clearing of the cylinders of the burnt charge. The pistons are long and are fitted with four eccentric rings, all located above the wrist pin. Lubrication channels running through the length of the hollow piston pins aid the oiling of the top connecting rod bearing.

The connecting rods are steel drop forg-

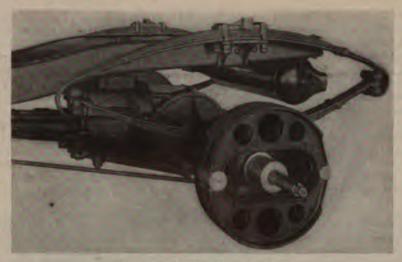

ings of I section. The lower end of each rod is provided with a spoon which dips in the oil in the splash basins for distributing the oil.

The radiators used on 1910 cars are of the Mercedes type, and are carried on two swivelled artillery trunnions, which, by allowing a slight swinging motion, entirely frees the radiator. With merely two bearing caps to remove the task of dismounting the radiator becomes easy, since it is held in position by only four cap screws. The radiator brackets are carried on the upper part of the frame, and the same castings also carry the lamp brackets and the fenders, thus doing away with a number of extra parts, as well as reducing the number of holes in the frame to two. The radiator is provided with a hard rubber filler cap in place of the ordinary brass cover. The water circulation is effected by a centrifugal pump geared to the cam shaft. A large fan, belted to the cam shaft, and a fan spoked flywheel provide a powerful forced draught of cool air around the motor,

Ignition is by a dual system through a single set of spark plugs, both magneto and battery being employed. A push button on the dash coil box is provided for self starting. A water jacketed Schebler carburetor is used. Lubrication is by a gear driven rotary pump, actuated by the cam shaft. The reservoir, which is self contained in the lower section of the crank case, has a capacity of 2 gallons, and is provided with a ball float and glass sight feed, as explained above. This system is automatic, and requires no attention other than to see that the reservoir is supplied with oil. Provision has been made for the lubrication of every moving part, and instead of oil holes grease cups are used.

The clutch is of the multiple disc type, composed of thirty-eight hardened steel discs running in an oil bath. This clutch is located inside the flywheel. The clutch rollers are hardened and ground, and are

HUB BRAKES AND REAR SPRINGS.

provided with individual grease cups. The clashing of gears when changing speeds is prevented by the use of an extension brake foot on the clutch roller, which comes in contact with a revolving disc on the clutch shaft when the clutch is released. As a further protection against noise in changing, the gear shaft rods are placed in parallel with the straight line propeller shaft, and so braced that they will always exert an even pull upon the gears.

The straight line drive has the shaft enclosed within a torsion tube, with but one universal joint, which is of the Hartford type. The change gear, which is of the selective sliding type, providing three forward speeds and reverse, is located in a specially constructed aluminum housing just forward of the rear axle. The same housing contains the differential gears. The gears have I inch face, and are oil treated. All shafts rotate on annular bearings. The sliding members are positively held in the different positions by drop forged locks, instead of by springs, so that no two gears can engage or partially engage at the same time.

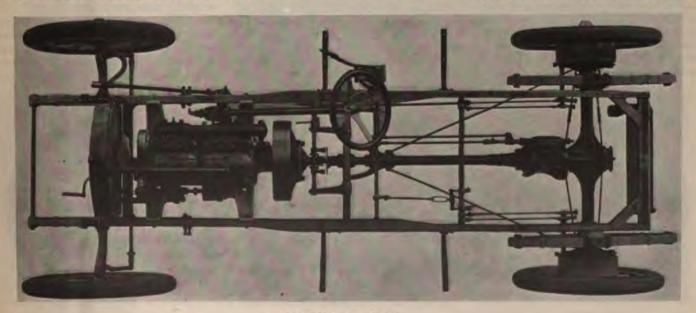

The rear axle is of the semi-floating type, and runs on Timken roller bearings. The axle spindles are heat treated. The entire rear system is housed and protected from dust and mud, but can be gotten at for inspection by the removal of four cap screws.

The front axle is of I section, is drop forged and heat treated. The front wheels revolve on Timken roller bearings.

In the rear axle Timken roller bearings are used next to the differential to take up the end thrust, and Hyatt roller bearings next to the wheels.

The steering gear is a worm and gear, with adjustment for taking up lost motion. It is provided with a ball thrust bearing, both above and below the worm. The steering arm is carried above the front axle instead of below. The spark and throttle control levers are located on top of the 17 inch steering wheel.

The frame is of pressed steel, dropped in the rear and narrowed in front to allow for short turning. It is 25% inches wide in the centre and heavily reinforced at all corners to prevent horizontal as well as vertical strain. All cross members are hot

PLAN VIEW OF CHASSIS.

riveted. A front bar between the springs also prevents vibration and serves as a protection for the lamps and radiator.

Thirty-four by four inch wheels are employed, the front wheels containing ten 134 inch spokes and the rear twelve spokes of the same size, with bosses for supporting the brake drums.

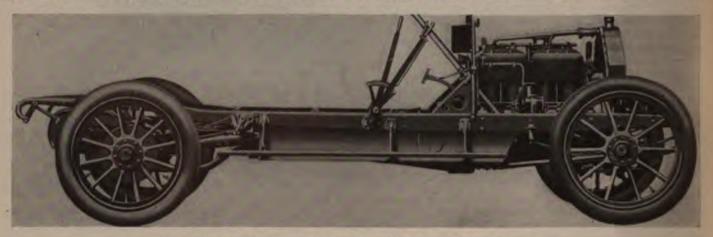

An entirely new system of four brakes is provided this year, these being all of the internal expanding type. Extra large brake drums are placed on the rear wheels. Brake control is by the usual method of pedal and hand lever. The brake rods are

New Features of Latest Stearns Thirty-Sixty Horse Power Cars.

Practically the only change in the new series of Stearns 30-60 horse power cars consists in the adoption of a dry multiple disc clutch, which has been tested out for the past thirteen months. The new clutch, which is illustrated herewith, both assembled and taken apart, consists of a comparatively small number of steel discs of large diameter, which are held and driven by hardened steel keys inserted into the rim of the flywheel. With the exception of the first and the last, these driving discs are

clutch is mounted within the flywheel and centred directly by the extension of the crank shaft, in such a way that there is no possibility of the proper alignment of the rotating members being affected either by the operating mechanism or any misalignment or angularity of its driving connection to the transmission.

The weight of this clutch has permitted to reduce the weight of the flywheel. The inner drum of the clutch is very light, and the floating member of the clutch has a very low moment of inertia. This renders gear shifting easy. The amount of inc-

RIGHT SIDE STEARNS THIRTY-SIXTY HORSE POWER SHAFT DRIVE CHASSIS.

carried inside the frame, and the brakes are operated through equalizers.

The front springs are semi-elliptic, 40 inches long by 2 inches wide, and with six leaves. The rear springs are full elliptic, with scroll ends, 40 inches long by 2 inches wide, and with seven leaves. All spring shackles are provided with individual grease cups. The muffler is placed horizontally across and under the rear of the chassis, and is provided with a cut-out. All bodies are of wood and sheet metal. Either a close coupled or five passenger touring body is supplied at the regular price.

The wheel base is 112 inches, with standard 56 inch tread. The cars are finished in Royal blue or Napier green, with a vermilion running gear. Thirty-four by four inch tires are furnished on Goodyear quick detachable rims.

faced on both sides with an asbestos fabric riveted to them with steel rivets.

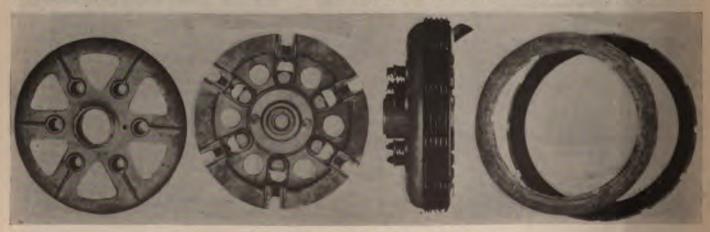

Between each of these discs are the hardened and ground steel driven discs, having integral springs which separate the discs when the clutch is disengaged. From these discs power is transmitted to the clutch drum, which is mounted on the ball bearing projection of the crank shaft, and is connected to the primary shaft of the transmission by a universally jointed shaft.

Owing to the large size of the discs and the character of the material lining them, the pressure required to operate this clutch is said to be extremely light, and is supplied by six coiled springs.

A suitably mounted thrust block in connection with the clutch pedal serves to release this spring pressure and disengage the clutch. The entire rotating part of the tional surface exposed makes for ease of gradual engagement, and at the same time overcomes any tendency to slip. A simple adjustment is provided whereby without disconnecting any of the operating mechanism wear is easily and quickly taken up.

Two other minor changes have been made in the 30-60 model, neither of which alters the main construction of the car nor its appearance. The ignition system now employed is the Bosch dual system, consisting of one set of plugs, with dry cells and high tension magneto. This system has been used on the 15-30 horse power Stearns model for considerably over a year.

The oiling system this year is a refinement of the system used on the 15-30 horse power model last year. The oil is carried in a reservoir in the bottom of the crank case, from which it is pumped and forced

PARTS OF STEARNS DRY PLATE CLUTCH.

through pipes on to the connecting rods. From here it drains back into the reservoir where it is screened, and then again passes through the pump. A bypass valve is also provided whereby a variable proportion of the total oil pumped can be made to pass through an overflow pipe leading directly to the reservoir, thus providing an easy method of controlling the amount of oil projected onto the connecting rods.

Further detail refinements are noticeable in other parts of the car, as instanced by the arrangements of the aluminum boot, designed to form a continuation of the crank case. It is easily removable, and permits of a very clean underbody protection.

The carburetor is of the well known Stearns type, but has been slightly enlarged.

#### The De Dion Eight Cylinder Chassis, Type C. J.

The De Dion-Bouton selling branch, 1649 Broadway, New York, have recently imported a 50 horse power, eight cylinder touring car, which, apart from the motor, has quite a number of interesting constructional features.

The bonnet is not much longer than on the average four cylinder of about the same horse power, but on account of the shape of the motor it is perhaps slightly wider than the average, and the side members of the frame are straight instead of being narrowed at the front, as is now the general practice. The wheel base is 130 inches and the tread 56 inches. The wheels are 36x5½ inches.

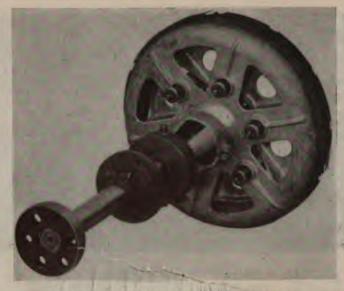

Beginning at the front of the machine, one of the first points observed is the use of a spring shackle at the front end of the front springs instead of at the rear. The advantage of this arrangement was discussed in the issue of October 13, page 414. The radiator is the "Gobe," which is manufactured by a peculiar process. A core of the shape of the water space is made of some alloy which melts at a low temperature. This is then put into an electroplating vat and coated with copper. When this reaches the proper thickness the core is removed from the shell by gently heating the whole, thus melting out the core and leaving the complete shell.

The clutch is the regular De Dion pattern plate clutch, and has no new features. The change gear, however, is quite interesting. It is of the four speed and reverse selective type.

The most striking feature of this gear is the method of lubrication. This consists in the use of a geared oil pump, with leads to the main bearings, as well as to the points at which the gears are in mesh, so that the gears will be properly lubricated with comparatively little oil in the case. This method of lubrication is similar to that employed in the motor.

The method of controlling the gear is also quite novel. The gear level has a straight back and forth motion on the sector.

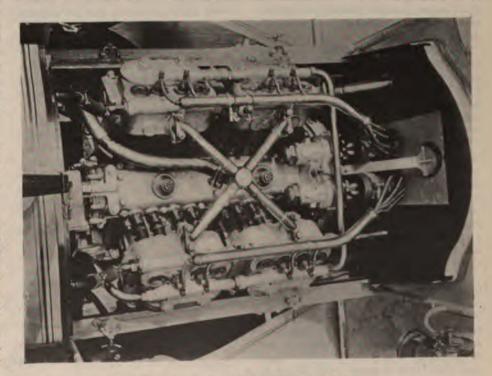

On both sides of it are short stub levers,

STEARNS DRY PLATE CUTTON ASSEMBLED.

which are connected to it by means of a sliding lug on the side of the gear lever, which is operated by a button on the top. Normally, if this button is not pressed, the arm which operates the third speed by a forward motion and the fourth by a backward motion is connected to the operating lever. However, pressing the button on top disconnects this arm and connects the arm which gives the second gear by a backward motion and the first by a forward motion. When the gear is in the first speed position the button can be still further depressed and the lever moved further forward, thus giving the reverse.

While on the subject of control, it may be as well to speak of the brakes. The right pedal operates an internal expanding brake on the rear of the change gear, and also first closes the throttle to the minimum opening. Neither the foot nor the emergency brake, however, is interlocked with the clutch. The rear construction is of the well known De Dion type, with bevel gear housing mounted on the frame and driving the rear wheels by short axles provided with Cardan joints. However, there are one or two new constructional features. In the first place, the propeller shaft is housed and made one with the bevel gear housing. This shaft has the bevel pinion affixed to it, and the distance between it and the gear can be varied from the front end of the housing by a collar just in the rear of the transmission. A universal of very limited motion, to allow for slight twisting of the frame, is formed by a collar having eight cylindrical studs set axially, which fit into

TOP VIEW OF DE DION EIGHT CYLINDER MOTOR.

EIGHT CYLINDER 1046 DE DION CAR

eight corresponding holes in the house the brake drum of the transmission.

The bevel gear housing is suspended from a cross member of the frame by a bolt passing through two lugs. The removal of this one bolt allows of the removal of the bevel gear housing complete from the frame.

The most interesting part of this car is undoubtedly the motor. This is of the eight cylinder V type, which has come into extensive use for flying machines and for other purposes where light weight is essential. The cylinders, which are 31/8×47/8 inches, are cast in pairs, with the valves on one side, and the two sets are at 90 degrees with each other. Two connecting rods of opposing cylinders work on one crank pin. The crank pin bearing is rigidly secured to one of the connecting rods which is in the form of a Y. The other connecting rod rotates on the outside of this bearing, between the arms of the Y. The relative motion between the two connecting rods, however, is comparatively small, being not more than 8 or 10 degrees.

The arrangement of the water circulating system is somewhat peculiar. The water is passed through a centrifugal pump driven from a cross shaft in front of the motor to a pipe which passes it from the left front cylinder to the left rear cylinder, thence to the right rear and thence to the right front. The return, however, is made by pipes leading from each set of cylinders to the right and the left of the radiator. The water is led into the cylinders at the top, between the valves and the cylinder proper, and is taken out at the outside of the valves. The inside of the jacket is suitably cored with partitions to ensure proper circulation. One cam shaft centrally located operates the valves of both sets of cylinders,

The carburetor, a Zenith, supplies the mixture, a single pipe leading to the centre of a cross shaped manifold, the arms of which lead to the centre of each pair of cylinders. Ignition is by Bosch h. t. magneto, two of these being employed and driven off of a gear on the rear of the cam shaft, each magneto being driven by its own gear. The working parts of the

magnetos are made very accessible through a pair of folding doors in the dash.

The order of firing is as follows: 1L, 2R, 3L, 1R, 4L, 3R, 2L, 4R. Fixed spark position is employed.

The lubrication is by the well known pump circulating system, which has now been used by this firm for a number of years. However, two novel adjuncts are employed to indicate the conditions as to quantity of oil and circulation. The first of these is a steel sounding rod permanently kept in an upright tube between the second and third cylinders on the right. This may be withdrawn at any time by means of a knurled knob on its top, and the depth of the oil in the "sump" noted. The other innovation consists in the use of a manometer or pressure gauge on the dash connected to the pump, this showing whether the oil is circulating properly or not. With the exception of this manometer, another for the water circulation, and the magneto switch, the dash is bare.

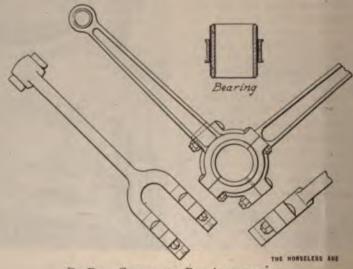

The regular De Dion oil pump is provided, which can be set to supply oil either to the motor, change gear case or differential case. The motor runs remarkably quiet and free from vibration. When it is throttled down one can almost count the separate valve clicks. It is said that the gasoline consumption is at the rate of 1 gallon per 9 or 10 miles.

#### The Salter Car.

Some time ago we announced the organization of the William A. Salter Motor Company, 1516 Oakland avenue, Kansas City, Mo. The company will manufacture a car embodying a number of Mr. Salter's inventions, which are herewith illustrated. The general features of the car are as follows: The engine is a four cylinder, vertical one of 4¼ inch bore and 4½ inch stroke, and is rated at 30 horse power. It is equipped with magneto ignition. A three forward speed planetary change gear is used. The car has a wheel base of 110 inches, and 32 inch wheels fitted with 4 inch tires. The total weight is given as 2,200 pounds. An option is given on a five passenger touring body or a roadster body.

The change speed gear is manufactured under Mr. Salter's patent No. 888,750. It is fitted with annular ball bearings, and is claimed to be very quiet running, as the gear drums travel at only half the speed of the engine when running idle, and at a slower speed when in operation. The entire gear is enclosed in an aluminum casing, and runs in a packing of semi-fluid oil. The low and intermediate speeds are obtained by contracting band brakes, while the high speed clutch is of an internal expanding ring engaging with the drum that carries the internal gear. The gears are all made from Krupp chrome-nickel steel; they are cut with 8 pitch teeth and are heat treated, and the company guarantee them against stripping or chewing out.

The reverse is not combined with the change speed gear, as in common practice, but is combined with the driving gears on the rear axle. The arrangement is covered by patent No. 853,120. The differential housing is provided with two bevel gears instead of one, and by shifting the bevel driving pinion between the two gears by means of eccentric bushings the forward

DE DION CONNECTING ROD ARRANGEMENT.

motion and reverse are obtained at will. The accompanying sectional view of the rear axle and driving shaft clearly shows the arrangement. Hyatt roller bearings are used in the rear axle near the hubs, Timken roller bearings near the differential, and a ball bearing is used at the forward end of the driving shaft.

#### Firestone Tire and Rim Novelties.

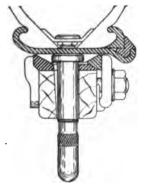

The 1910 Firestone demountable rim (for all quick detachable and clincher tires) will be exhibited for the first time at the Atlanta Show. When used with quick detachable tires this rim permits of repeated tire changes while on the road, even after the motorist has used up his spare tires. Such changes may be made right from the wheel without reference to the demountable feature, and wholly independent of it.

This is made possible by use of a sleeve which fits over the valve stem between the dust cap and base of the quick detachable rim, as illustrated herewith. No locking nut is used, the dust cap on the valve stem serving to hold the spreader in place or release it when the motorist wishes to remove his tire and tube. During this operation the sleeve remains unchanged in its position in the hole in the felloe.

When the rim is demounted in the regular way the sleeve, dust cap, etc., slide through the hole in the felloe.

The Firestone Company have now practically discarded exclusive clincher demountable rims on account of the staybolt nuisance. They have done this in view of the fact that their new rims do away with staybolts, and make it a very simple matter to fit a tire on the spare, detached rim.

At this show the Firestone Tire and Rubber Company will exhibit for the first time their 1910 pneumatic tires. These differ

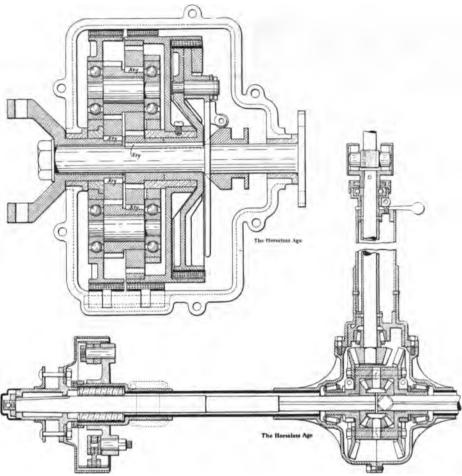

Section of New Firestone Demountable Rim.

from the 1909 product, as in all sizes of the round tread tires the tread has been increased exactly 25 per cent. in thickness and in the non-skid 33½ per cent.

## Coppock Motor Car Company Reorganized.

The Coppock Motor Car Company, of Decatur, Ind., has been reorganized as the Decatur Motor Car Company. The capital stock of the new company is \$150,000, and the following officers have been

SALTER TRANSMISSION AND REAR AXLE.

elected: M. E. Bracket, president; W. J. Vesey, vice president; Julius Haugk, treasurer, and D. L. Quinn, secretary. The company has been operating in Decatur for some years, but was handicapped by lack of working capital. It has on hand material for twelve of its motor trucks, which will be completed immediately, and it is the intention to secure material for twenty-five additional cars.

# Topics for Discussion of the Winter Meeting of the Society of Automobile Engineers.

Among the subjects that discussion at the winter meeting has been asked for are:

Standardization of Pneumatic Tires.
Taxicabs—Requirements and Operating
Cost.

Carburetors—Kerosene Carburetors.

Railway Motor Cars

Drawing Room Systems.

Truck Tires.

Valves in Head versus T Heads.

Alcohol as Fuel in Internal Combustion Motors.

Silencer.

Radiator, Design and Efficiencies.
Critical Temperatures, Cooling Curves of

Critical Temperatures, Cooling Curves o Alloy and Other Steel.

Two Cycle Motor Efficiency and Results. Journal Loads in Transmission Gears.

Placing Society on More Professional Basis.

Efficiency of Spur, Bevel, Worm Gears and Universal Joints.

Relative Efficiency of Four Wheel Front and Rear Drive of Commercial Vehicles.

Detachable versus Demountable Rims—Combination Rim.

Commercial Vehicle Depreciation.

No doubt many will be present during one or the other of this winter's shows at New York. Such of these as would care to be present at the professional meeting of the Society of Automobile Engineers may be assured of a hearty welcome. Their contribution to these discussions will be as welcome as will also more complete papers; the latter should be sent into the society's offices at No. 2 Rector street, New York, to be in the society's hands by November 30 for printing and general distribution before the meeting. Papers and discussions from an engineering standpoint, including also matters of operating finances, are in order

#### Municipal Autos a Campaign Issue.

Municipal automobiles have been made an issue in the city campaign now on in Indianapolis. Two of the mayoralty candidates are charging that members of the present administration use the city automobiles for attending baseball games, picnics and social events. The city owns about twelve cars, distributed among several departments.

#### **COMMUNICATIONS**

## Too Frequent Valve Grinding Required.

Editor Horseless Age:

I should be glad if you would suggest to me in your "Communications" column a remedy for a rather peculiar trouble. I have asked several persons and have thought the matter over carefully.

I have a new car, which I have driven about 1,500 miles so far. The engine is 41/2x41/2, and is eminently satisfactory and flexible, except that about every 200 or 300 miles one or another of the exhaust valves has to be ground. All four of the valves have been ground, and the trouble is recurring. The valves seem to pit, and carbon appears to be the principal trouble. The engine never overheats, not even on long continued, heavy grades, and there have never been any symptoms of preignition. The mixture is perfect; there is a remarkable freedom from smell from the exhaust. and there is no oil smoke. The car (which has showed 52 miles an hour on the road) can be throttled down to 7 miles an hour on high gear, and the engine runs smoothly, as it also does at all intermediate speeds up to the maximum. The oil is that advised by the manufacturers of the car, and is the best I can get. My gasoline is of good quality. My plugs have not sooted up; I have only had to clean them once (although I often inspect them). I run kerosene through the cylinders once or twice a week (according to distance traveled). Practically all my driving is done in the country, and so I drive with the cut-out open much of the time.

There is no missing until suddenly the engine runs on three cylinders, and then I know that one of the exhaust valves needs grinding; for I get out, and, having stopped the engine, on cranking I find no compression in one cylinder. On grinding the proper valve all is well.

The car is most delightful to drive; the engine is extremely flexible, and, as I like to put it, "very obliging"; it will do any thing in reason; the only trouble is that queer trouble with the exhaust valves (which are large). Could it be that the metal of the valves is defective? It is a nuisance to have to grind them so often. The same valve does not have to be ground each time, but, as I said before, about every 200 miles or so a valve has to be ground. In a car that I owned before I only had to grind the valves about every 3,500 or 4,000 miles. I had odometers on both cars, and kept and still keep a mileage record in a book. W. R. VAN BRUNT.

[From your letter we are not quite convinced whether the valves actually need 'nding when there is no compression.

Sometimes, owing to lack of lubrication, the valve stems will become tight in their guides, and the valves will either not close at all or close very sluggishly. Whether this is the trouble you can determine by watching the valve stem and spring while the engine is being turned over by hand. The grinding would, of course, free the stem in its guide and thus remove the trouble temporarily. If this should be found to be the cause of the trouble we would recommend reaming the guides out slightly larger.

It is also possible that the valve heads warp, or it may be that they are made of an inferior material which is easily attacked by head. A test for warping consists in smearing a paste of red lead and oil over the seat, letting the valve down on it and then turning it slightly back and forth by means of a screwdriver. If it is not warped the paste will be squeezed off of the seat equally all round; that is to say, if neither the valve nor the seat is warped.

We are inclined to think that your trouble is due to one of the above two causes. If the valves are large and if there are no signs of overheating there does not seem to be much chance of such frequent pitting of the valves, unless the latter are carried in cages.—ED.]

## Self-Centring Quality of Steering Wheels.

Editor Horseless Age:

Should like to have information regarding the following, if you will be kind enough to give it to me:

Why is it that the front or steering wheels on one automobile will have a tendency to straighten themselves or stay straight if the hand wheel or lever is released, and the wheels on another automobile will have the opposite tendency?

I have several automobiles, and all of the gasoline machines, if I were rounding a curve or struck a rut, would have a tendency to straighten up if I had a light hold on the steering wheel. But I have an electric machine with lever steering, and I am afraid to put any speed on it for the reason that if I start to wabble the wabble gets worse and I would upset, for the tendency of the wheels is to turn more to the side instead of straightening up, and in pulling them back straight with the lever the hand flies over to the other side too far and thus starts a dangerous wabble.

I don't know if I explain this so you can understand it, but I think you will know what I mean.

Originally the electric steered all right, but I had new, heavier wooden wheels put on in place of the suspension wheels and some other changes made, and I don't know what the cause of this trouble is.

My wheels are a little further apart at the bottom than the top; in other words, the axis of the steering knuckle is out of plumb a little wider at the bottom.

Perhaps it should be the reverse of this,

or perhaps this has nothing to do with it.

Can you give me information that will help me out of my difficulty? If so I shall be much obliged.

P. M. SHARPLES,

[Almost every gasoline car is equipped with a non-reversible steering gear, which insures that the steering road wheels stay at the angle to which they are turned, and no amount of bumping can move them. The non-reversible mechanism usually consists of a worm and wheel. If you are familiar with this machine element you know that by turning the worm you can turn the wheel, but it is absolutely impossible to turn the worm by exerting a circumferential pull on the wheel.

The steering levers of electric vehicles are generally connected directly to the steering knuckles, and any shocks received by the wheels are therefore transmitted to the steering lever. The way the steering linkage is usually arranged the system is in an unstable balance. That is, if we suppose the wheels to be turned straight ahead and if one of them then hits a road obstruction, the wheels-supposing the driver has released his grip on the lever-will then be jerked to one side, and there will then be no tendency for them to straighten out again. This is on the supposition that the two axle spindles are exactly parallel with the front axle. The steering gear can be made self centring, to a certain extent at least, by placing the axle spindles back of the steering knuckle pins or pivots.

In the case of your electric car, if the overhauling of the steering gear resulted in an undesirable change in this respect, we can only infer that the tie rod connecting the two steering knuckles is so adjusted that the two front wheels "toe in" in front. If these wheels were wider apart in front than in the rear they would have a slight self centring tendency, whereas if they are wider apart in the rear their equilibrium will be very unstable. However, the tie rod should be so adjusted that they are the same distance apart in front and rear, as otherwise there will be abnormal wear on the tires.—Ed.]

#### Dependence of Tire Life on Cross Section and Wheel Diameter.

Editor Horseless Age:

I have read with a considerable amount of interest your article in the issue of September 22 in reference to tire life, taking into consideration the wheel diameter and cross section. I have taken a very keen interest in the matter myself, and my experience can be summed up relatively shortly.

In regard to the difference in life between, say, a 34 inch tire and a 40 inch tire. I find that the smaller tire is actually the one that lasts the best, the larger tires bursting much more frequently than the smaller ones. I can hardly believe that the larger size of the wheel causes this, as owing to the greater amount of surface in contact with the ground it is unnecessary to pump the tire quite so hard to get exactly the same supporting power through less pressure of air per square inch.

Personally I have put the failure of the large tire down to the fact that it is a size which is not made in large quantities by the tire companies today, or at any rate in Europe, and for some reason or other it does not appear to be so well made as the smaller size. When I started these experiments I had it in my mind that the larger diameter tire would last longer than the smaller one.

So far as the cross section of the tire is concerned, I find that the increase of the cross section materially adds to the life of the tire, and I think it does this for two resons:

- I. The tire with the larger cross section does not have to be pumped so hard to support the weight, and, therefore, there is less stress on the walls of the tire.
- 2. The actual angle of the wall under running is considerably less on the larger cross section than on the smaller one; and again, the actual surface of the tire in contact with the road wears away less rapidly with the large tire than with the smaller one.

From the point of view of cost per mile I find that if you have a tire section big enough for its work further increase, although increasing the comfort of the vehicle, does not decrease the cost of running per mile to any appreciable extent, but, of course, when you increase the size of your cross section of tire on a car which has been previously under-tired the material gain in economy is most noticeable.

In respect to your next query, whether the resilience of wood wheels and the longer. spokes of a 36 inch wheel, as compared with a 30 inch wheel, really efficiently aid in buffing the road shocks, I am quite satisfied that there is something appreciable to be gained in this direction, but its most noticeable effect is when using wire wheels of the suspension type. The same car with the same size of tire (both diameter and cross section) and doing the same work regularly will run 20 per cent. further on its tires on the suspension wire wheels than it will run on wooden wheels, and I cannot put this down to anything else except the fact that there must be some give in the actual rim of the wheel which helps the life of the tire. I admit that it seems most difficult to believe that this should be a fact, but, of course, one has to remember that on the suspension wheel the portion of the tire in contact with the road has nothing to prevent it flattening out, except the strength of the rim, the steel rim spokes practically having no strength in a compression direction.

I certainly believe that this point in regard to economy on tires is one that would stand a very considerable amount of careful investigation. I am in a very unique position to test this, as I live some 40 miles out of London and make the same journey

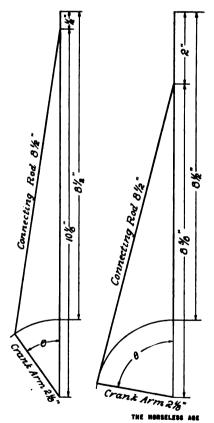

on the same car very frequently, and practically always at the same average speed. For a long time I could hardly believe these results were accurate, but they have been confirmed by many other users of Napier cars, who have had wire wheels fitted in place of the wooden ones, and it is quite an outstanding feature to notice how many of them write and suggest their tires last much longer since the wire wheels were fitted to their cars.

S. F. Edge.

## Ignition Timing by Flywheel Marks.

Editor Horseless Age:

Will you please give me the formula for marking off the position on the flywheel of the time of the spark, knowing the stroke of the piston and the diameter of the flywheel? That is, I wish to know how to time the spark in my auto engine. The manufacturers say that in the extreme retarded position the commutator should be so set that the electric connection is made when the piston is one-half inch past the top centre, and in the fully advanced position it should be so set that it will make

the electric connection 2 inches before reaching the top centre. Now, then, with the piston on top centre and the flywheel marked in that position, how shall I figure out how far to move my flywhel from this position to have the piston one-half inch past the top centre and 2 inches before the top centre, respectively? My piston stroke is 4½ inches, and the diameter of my flywheel is 14 inches.

SAMUEL H. WATSON.

[To accurately calculate the motion of a point on the flywheel corresponding to a

motion of one-half inch and 2 inches from the dead centre, we require to know the length of the connecting rod. But since no very close figures are required, we will assume that the connecting rod is twice as long as the piston stroke, viz., 8½ inches, which cannot be far from the truth. By the connecting rod length we mean the distance from the centre of one connecting rod bearing to the centre of the other bearing.

When the crank is in the top centre position the distance from the crank shaft centre to the piston pin centre is evidently  $8\frac{1}{2} + 2\frac{1}{6} = 10\frac{1}{6}$  inches. When the piston is one-half inch from the end of its stroke this distance is one-half inch less or  $10\frac{1}{6}$  inches. The centre lines of the cylinder, connecting rod and crank arm then form a triangle whose sides are  $2\frac{1}{6}$  inches,  $8\frac{1}{2}$  inches and  $10\frac{1}{6}$  inches long, respectively. What we wish to know is the value of the angle  $\theta$  between the shortest and longest sides, or the angle through which the crank has moved after passing the dead centre.

According tó a trigonometrical rule we

$$\cos \theta = \frac{2\frac{1}{8}^2 + 10\frac{1}{8}^2 - 8\frac{1}{2}^2}{2 \times 2\frac{1}{8} \times 10\frac{1}{8}} = 0.763$$

$$\theta = 40\frac{1}{8} \text{ degrees.}$$

As your flywheel is 14 inches in diameter, it has a circumference of  $14 \times 3.1416 = 44$  inches (approx.). The total circumference is equal to 360 degrees, and the length of arc corresponding to  $21\frac{1}{2}$  degrees is found by a simple proportion.

360: 
$$44 = 40\frac{1}{4}$$
:  $x = 4.92$  inches.

Consequently a point on the flywheel moves practically 5 inches while the piston moves down one-half inch from the top end of the stroke.

The calculation is the same for the position of the piston 2 inches from the top end of the stroke. The sides of the triangle are then 21/8 inches, 81/2 inches and 85/6 inches.

Cos 
$$\theta = \frac{2\frac{1}{8}^{\frac{3}{8}} + 8\frac{1}{8}^{\frac{3}{8}} - 8\frac{1}{2}^{\frac{3}{8}}}{2 \times 2\frac{1}{8} \times 8\frac{1}{8}} = 0.17$$
  
 $\theta = 80\frac{1}{8}$  degrees (approx.)  
 $360: 44 = 80\frac{1}{8}: x$   
 $x = 10$  inches.

Consequently the point on the flywheel rim moves to inches while the piston moves down 2 inches.—ED.]

## Repair of Cylinder Damaged by Broken Valve Head.

Editor Horseless Age:

Please give me your advice on the following:

A valve head pulled off in my machine and, falling on the piston, a hole was punched in the cylinder head; not through to the outside, but between cylinder and water jacket. What suggestion can you make for repair? Would a weld by the oxy-acetylene (autogenous) system be a reliable repair under the circumstances? Any suggestions which you can make, eighar

through the columns of THE HORSELESS AGE or by letter, will be greatly appreciated. P. J. W.

[Without having seen the injured cylinder it is somewhat difficult to express an opinion on the possibility of a repair. We presume that the hole made by the valve head is in the cylinder head and not in the wall of the cylinder. The only question then is whether it is possible to get at the break with the torch. If the cylinder has a removable jacket cover plate it is probably quite accessible, but if there is only a plugged hole in the top of the water jacket it may be impossible to properly get at the broken place. If the point can be reached a reliable repair can be made.—ED.]

## Responsibility of Owner Who Lends His Car.

Editor Horseless Age:

In your issue of May 26, 1909, there was an editorial on "Legal Responsibility for Chauffeur's Acts." I am interested in the question, and would like you to send me the names of the different cases on the subject. I should like especially to read the cases holding that an automobile owner is not legally responsible for the acts of a person to whom he has loaned his automobile, such as his son or his daguhter.

I have been a subscriber to your magazine for several years, and would be very much obliged for the information.

E B COLKET

[We have looked over our files for cases of the kind referred to and find the fol<sup>3</sup> lowing:

Where a daughter nineteen years of age was accustomed to use an automobile, asking permission when her father was at home, but sometimes taking it without permission when he was not at home, it was held that the relation of master and servant did not exist where she was not driving other members of the family, but was using the machine as a means of recreation and pleasure for herself and her own friends.—Doran vs. Thomsen, N. J. 71, Atl. 296.

An owner of an automobile is not liable for an injury caused by the negligent driving of a borrower, if the machine was not used at the time in the owner's business.—Doran vs. Thomsen, 66 Ht. Rep. 897; Beaverman vs. Hart, 105 N. Y. S. 107.

Where the owner or person in possession of an automobile merely permits another to use it, the latter does not thereby become the agent or servant of the former, so as to charge the one with the other's negligence—Lewis vs. Amorous, 59 S. E. Rep. 238.—Ed.]

#### Queries.

Editor Horseless Age:

I would be pleased to have the following questions answered in your columns:

I. What is the best way to locate air leaks between the carburetor and the inlet valve in a water cooled motor and at would be best way to remedy same?

- 2. What is best and safest way to warm up the carburetor and inlet manifold on a very cold day, when an electrical device is not available?
- 3. When it is impossible to heat a private garage or building in which a car is to be kept in the winter, wouldn't an air cooled car be better to operate than a water cooled car, when the car is to be used every day some weeks and two or three times a week at other times during winter?

  R. M.

[One of the best methods of locating a leak in the inlet system is to spread soap suds over the inlet pipe and its joints to the engine and carburetor, and then force air into the inlet pipe in some manner (by blowing into it with the mouth, for instance), when soap bubbles will be formed at the point of the leaks. Another method consists in passing a burning cigar or cigarette over the inlet pipe while the motor is running. At the points of leaks the smoke rising from the cigar will be drawn toward the leak.

The best method of repairing the leak cannot well be specified without knowing its nature. If it is just a pinhole in a drawn tube or cast manifold, it can easily be closed by solder, but if it is at the joints some other process may have to be resorted to. If you have once found the leak any mechanic will know how to repair it.

A good way to warm up the inlet pipe, and especially the carburetor, on a cold morning, to facilitate starting of the motor, is to soak a large rag in boiling water and to apply that to the carburetor and inlet pipe.

An air cooled car has less need of being kept in a heated garage in winter than a water cooled car. There is no danger of its being damaged when stored in an unheated barn, but, of course, the motor will be stiff in the morning and rather harder to start than if it was kept in a heated barn. Where a car is to be used almost continuously during the winter, the air cooling system offers decided advantages.—ED.]

#### The Saurer Motor Truck Company.

The Saurer Motor Truck Company, which was recently incorporated under the laws of New Jersey, with a capital stock of \$200,000, and with Albert T. Otto as president and W. D. Sargent as one of the incorporators, has made arrangements with the Q. M. S. Company, of Plainfield, N. J., whereby the machines will be manufactured and assembled at these works. The company plans to begin business at once by importing immediately 150 complete chasses, as well as the parts for 150 more. which will be assembled in Plainfield, and then gradually take up the manufacture of the entire truck. The main office of the company will be in the Motor Mart, 1878 Broadway, New York, where parts will be kept in stock and all ordinary repairs made.

#### New Factory for Breeze Carburetors.

The Breeze Carburetor Company, of Newark, N. J., are building a reinforced concrete factory for the manufacture of their carburetors, strainers, check valves, etc. Two months ago they purchased a building site on South street, between Jefferson and Pacific streets, comprising about 25,000 square feet. The machine shop alone will cover about 10,000 square feet and will increase their present capacity tenfold. The new factory will be completed some time in January. The company's offices have recently been moved from 276 Halsey street to 14 William street, and the space vacated by the removal is now being used for manufacturing purposes.

## The Electrical Show at Madison Square Garden.

At the electrical show which is now being held at Madison Square Garden, New York, are exhibited quite a number of automobile accessories, as well as some few electric automobiles. The Studebaker Company exhibit a 5 ton truck, with double motor equipment, and also an 850 pound delivery wagon. This is equipped with an ampere hour meter. These meters have been tried out by this company, and are said to have given remarkably good results in service.

The Lansden Company, of Newark, N. J., also show a couple of electric vehicles, a light delivery wagon, and also a new pattern of depot or dock truck. This machine is designed for handling goods in factories, on large docks and in warehouses, and is equipped with only three small wheels. Two of these trucks are at present in use at the Hoboken station of the Lackawanna Railroad for handling baggage.

Stanley & Patterson are exhibiting their line of wireless batteries and boxes, as well as a line of automobile accessories. The General Electric Company show their mercury vapor rectifier for charging batteries. Another part of their exhibit which is featured consists of 6 volt tungsten lamps for automobile lighting.

The American Electric Lamp Company also show a line of 6 volt tungsten lamps for this purpose, and also a special switch by means of which the side and tail lights alone can be lighted or these together with the searchlight.

One of the most interesting exhibits is the Murphy electric rectifier, made by the company of that name, located at Rochester. N. Y. This machine is of the type operated by a synchronous motor, but the method of commutating the current is quite ingenious, the purpose being accomplished by purely electrical means. One feature of the device is that the voltage delivered can be regulated at will up to the full capacity of the transformer, and that without the use of resistance coils. A remarkably high efficiency is claimed for this device.

The greater portion of the exhibits are, of course, only of indirect interest to the motorist.

# Commercial Applications

#### Los Angeles Motor Express Lines. By W. V. Woehlke.

Within the last nine or ten months Los Angeles has awakened to the possibilities of the motor truck in the express and freight business, and is making up for its belated awakening by the rapidity with which motor trucks find buyers and users. Conditions around Los Angeles are as nearly ideal for the profitable employment of motor trucks as it is possible for them to be. The city is surrounded by more than a score of suburban towns, with populations ranging from 2,000 to 30,000. The roads are fair, oiled highways predominating, and within a year most of the suburban towns will be connected with Los Angeles by a system of excellent roads now under construction at a cost of \$3,500,000. These new roads will materially reduce the cost of operating and maintaining commercial vehicles, and a boom in the motor truck business will probably follow their comple-

Eight months in the year not a drop of rain falls on the roads, and the balance of the year the drivers have to contend only with rapidly drying mud on those roads lacking an oiled surface. Snow and ice are unknown, and the garages and storages places do not have to be heated, and may be of the lightest construction, so long as they keep the rain out.

#### CAUSE OF BACKWARDNESS.

The delay in the introduction of the motor truck in Los Angeles was mainly due to the enormous business in pleasure cars—a business that fully occupied the energies of the agents, and prevented them from venturing into a new field. When once the ice was broken and one firm was demonstrating to prospective buyers the advantages of the motor truck and to other agen-

cies the profits of the business, others fell into line and sales multipled. Within the last four months over twenty motor trucks were sold, and in the last six weeks agencies have been established for half a dozen different makes.

Of the twenty-odd towns around Los Angeles but four are so far served by motor express lines. Of the four lines one makes its headquarters in Los Angles, delivering in the suburbs of Santa Monica, Ocean Park, Venice and way stations, while the other three lines come from Pasadena, Long Beach and Santa Ana to Los Angeles all of them touching intermediary points. All of them formerly employed horses for the work the motor trucks are doing. The shortest line is the route covered by the Pasadena Transfer and Storage Company, operating between Pasadena and Los Angeles, a distance of 10 miles. The Pioneer City and Suburban Delivery Company runs a line 16 miles long to Santa Monica and other beach points, while the Long Beach Transfer Company covers a distance of 22 miles between the two points. The Santa Ana Transfer Company has the longest haul, 33 miles. Transfer companies of four other towns are at present negotiating for the purchase of motor trucks to replace their horses.

#### PICKING UP AND DELIVERING,

All of the trucks pick up their loads at one end without assistance, delivering in the same manner. Thus the Pioneer City and Suburban truck delivers and picks up all its load at the points it touches, while in Los Angeles only the bulky portions of the load are delivered and collected by the truck, light delivery cars and teams collecting and distributing the balance. The Pasadena, the Long Beach and the Santa Ana express lines, on the contrary, have assistance in picking up and delivering in their home towns, and none for the Los Angeles end, though all of them have headquarters with Los Angeles concerns for the receiving of orders.

#### PIONEER COMPANY'S SERVICE.

The express line from Los Angeles to the beach towns of Santa Monica and Venice, operated by the Pioneer City and Suburban Delivery Company, has been in existence the longest of any of the undertakings. The truck, a 21/2 ton Reliance car, with a two cycle, water cooled engine, developing 30 horse power, with a maximum speed of 25 miles, started in service almost five months ago, and has made daily trips with the exception of two days when it was laid up for repairs, owing to an attempt to change the circulation pump. Before the truck was put into service five horses were necessary. One team was used on the outgoing and the second team on the return trip, with the extra horse as substitute to give one of the other four a day of rest every week. With the horses the trip of 16 miles was made in two hours and a half. A ton was the limit of the load. The truck makes the trip in one hour and ten minutes, carrying loads varying from 900 to 3,500 pounds. It makes from fifty to ninety stops for delivery per day, and besides the towns served by the teams, it has extended its field into Palms, Sawtelle, Soldiers' Home, Ivy and other places. The average length of the distance covered daily is 55 miles, and the cost of operation and maintenance, according to Manager Ramsey, is slightly less than the cost of the teams,

#### CATERS TO EXPRESS SHIPPERS.

The truck does not carry heavy, bulky freight. The line caters principally to the express shippers, and comes into direct competition with the Wells-Fargo Express Company. All the towns touched are connected with Los Angeles by trolley lines, over which the Wells-Fargo has the exclusive express privilege. The minimum charge per package on the Wells-Fargo is 25 cents, with 10 and 15 cents added for delivery, according to the distance, making the lowest rate 35 cents in all. The truck's lowest rate is 15 cents per package, with no delivery charges, and this reduction is at-

Pasadena Transfer and Storage Company's 2 ton truck in front of Los Angeles office, with outgoing load.

Motor truck of Pioneer City and Suburban Delivery Company, with partial return load.

tracting the attention of shippers. The firm calculates that the average outgoing load pays all expenses of operation and maintenance, including the wages of driver and helper, and that the return load represents the profit. In consequence it is endeavoring to work up a return business, and has met with success, suburban shippers having discovered that, besides lower charges, the truck gives more regular and faster service than the express company, the goods going out the minute they are delivered to the truck, while they may lie from twelve to sixteen hours in the express office before being transferred to the cars.

#### LACK OF RESERVE EQUIPMENT FATAL.

About a year ago another firm started in the express business between Los Angeles, Santa Monica, Ocean Park and Venice with a motor truck, enjoyed good patronage and profits, and then disappeared from the field. The failure was due to several causes. The firm made a flat rate of 11 cents per 100 pounds freight, collected and delivered, in an endeavor to compete, not only with the express service, but with the freight department of the electric road as well. Even at this low rate the truck paid expenses when the freight was not too bulky in proportion to the weight; but when, for instance, half a ton of breakfast food filled the entire truck, the firm lost money. To avoid this condition the firm built up a good trade in perishable goods, such as meats, fruit, etc., at higher rates, but it was wrecked through the lack of reserve equipment. Regular service is the prime condition in moving perishable goods, and when the truck went out for repairs, with no other truck to take its place, the enterprise failed.

#### COMMERCIAL GARAGE SERVICE.

To make possible the successful operation of a single truck by one firm, the manufacturers of the truck, through their Los Angeles agency, have made arrangements with buyers for reserve equipment. The agency, the Pioneer Commercial Automobile Company, furnishes garage service for all the trucks it sells at rates below the average of public garages. The service includes storage, washing and polishing. If, during the first year, repairs are necessary through defective parts, faults of construction, etc., the agency makes the repairs free of charge, and during the time required for the work furnishes a truck gratis to take the place of the one out of commission. If the breakage is due to the fault of the driver a reserve truck is furnished at a rate less than the cost of a team for the same period. Wherever possible repairs are made at night to have the truck ready again in the morning.

The Pioneer City and Suburban Delivery Company is owned by H. C. Fuller, who also owns the Pioneer Trucking Company. Besides the 2½ ton truck on the Santa Monica express line, he operates a 3½ ton Reliance truck for long distance heavy hauling. running from Los Angeles to all the

bs up to a distance of 40 to 50 miles.

Before the advent of the truck horses were used on these long hauls, the firm charging \$1.50 per hour for their services. Even at his own rate the service was not profitable to the owner since, in his own words, "the long hauls were horse killers." While the operating and maintenance expenses of the freight truck are about the same and no higher rate is demanded, the service now shows a profit, besides giving the firm reserve equipment for the express line.

#### DELIVERY CARS PROVED TOO LIGHT.

Besides the two trucks, Fuller has been operating four one cylinder light delivery cars. He handles a large portion of the suburban delivery of almost all of the Los Angeles department stores, but the delivery cars will be disposed of as soon as possible. They were found to be too light for the demands made upon them, and are to be replaced by trucks. Department stores will not hand over their delivery to an outside concern unless that concern performs the service at least as cheaply as the department store could with its own equipment. The margin of profit for the delivery company, therefore, must be narrow if it wants to get the business, and the volume of the business must be large if the delivery company is to make a profit. In consequence the light delivery cars, put on the hardest, longest routes, of course, have to travel fast and make numerous stops in order to pay expenses. They were equal to the task, but nevertheless the upkeep proved too expensive on account of the hard usage they necessarily received.

The two trucks and the four light delivery cars are stored in the garage of the Pioneer Commercial Automobile Company, a subsidiary concern, fully equipped with drill press, engine lathe, forge, emery wheel and small tools, together with a line of parts. It is the intention of the concern to double its garage space, and make a bid for a portion of the commercial vehicle business that is rapidly growing up in Los Angeles

The trucks are equipped with solid tires, 36x5 inches on the front wheels and 36x7 inches on the rear set. Both the tires and the chains are guaranteed by the manufacturers for 5,000 miles. Though both trucks have exceeded this mileage, no replacement has been necessary so far.

#### PASADENA EXPRESS LINE.

The route of the Pasadena express line, operated by the Pasadena Transfer and Storage Company, H. G. Cattell and John C. C. Oy owners, covers a much shorter distance. The distance between Los Angeles and Pasadena is approximately 10 miles, with a steady grade almost threequarters of the distance from Los Angeles to the other end. The firm operates two two-cylinder Rapid trucks, one of I and the other of 2 tons capacity. The trucks make one trip a day, collecting their load in Los Angeles and delivering it at the storehouse in Pasadena, where it is broken up and delivered, partly by the truck not on the long trip and partly by horse ve-

hicles. According to the size of the load, the I or the 2 ton truck is sent out. If no stops are made at either Highland Park or Garvanza, the trip usually lasts an hour. Including the collecting and delivering of the loads, the daily average of the trucks is 45 miles. Paying loads are carried both ways as a rule, though the return trip usually shows the lighter amount of business.

## THE LONG BEACH WAREHOUSE AND TRANSFER COMPANY.

though its 2 ton Rapid truck has been in service but two months, has come to the conclusion that self propelled trucks, as compared to horse drawn vehicles, are a success and a paying investment, and the company will probably replace more of its horses with motor trucks. The truck running between Long Beach and Los Angeles, a distance of 22 miles over indifferent though almost level roads, performs work for which formerly six horses were required, and these six horses had difficulty in handling loads that are often exceeded by the truck. Including two stops for water, the truck makes the trip to Los Angeles in two to three and a half hours, according to the size of the load. Household goods and furniture constitute the main items of the loads, though a good deal of express matter is carried. Like all the other motor truck lines running to Los Angeles, the Long Beach truck has to compete with the freight and express service of the electric road, the railways and a number of transfer companies using horses. The truck is stored in the company's barns, minor adjustments and repairs being made at the shop of the selling agency in Los Angeles.

#### SANTA ANA TRANSFER COMPANY.

The longest haul of the motor lines established around Los Angeles so far falls to the 2 ton Rapid truck of the Santa Ana Transfer Company, which has to cover a round trip 60 miles long daily. Loads of general merchandise and household goods are carried either way, with the usual competition.

With all the motor truck lines gasoline and oil have been the chief items of expense. The next few months, with their rains, mud and rutted roads, will be the crucial test, but the experience of one of the lines last spring seems to indicate that the trucks will stand the test if carefully handled by competent, experienced drivers. The average distance for I gallon of gasoline on all of the lines varies between 3 to 7 miles, according to the load and the grade. None of the lines kept an accurate record of either the gasoline or the oil consumption, the owners relying upon a rough computation of the total monthly cost and receipts to compare the efficiency and earning capacity of the motor vehicles with the cost and profit of the service rendered by horses.

#### LACK OF EXPERIENCED DRIVERS.

The main trouble in the operation of the motor trucks has been the difficulty of find-

ing experienced drivers for them. To surmount this obstacle one of the selling agencies agrees to furnish experienced drivers, or, if the buyer prefers, a man selected by him will be put into the shop for five or six weeks before he is sent out with a truck, accompanied by a mechanic. Another agency instructs prospective drivers for one or two weeks in its shop. Drivers of pleasure cars are loath to enter the commercial field. The change means too much work, not only on the driver's seat but also in handling the load. Still, those drivers who have made the change are satisfied. They have to work only a stated number of hours, with no one to find fault while they are on the road, and with opportunities to work up to better positions, opportunities wholly lacking in the average position as driver of a private touring car.

Practically all the bodies of the trucks as furnished by the factory proved to be too narrow. In consequence one of the selling agencies has installed facilities for the manufacture of bodies, receiving only the chassis and the motor from the factory and building a body to suit the requirements of the buyer.

#### Motor Mail Wagons in Philadelphia.

The Philadelphia post office is now using five motor wagons for the collection of packages and mail in the northern and northeastern sections of the city. This service was started on October I and the five motor wagons replaced ten of the old horse drawn vehicles. The vehicles, one of which is herewith illustrated, were built by the Autocar Company, of Ardmore, Pa. They consist of one of the regular Autocar commercial chassis, on which is mounted a body built to the specifications of the United States Government.

#### More Cars for Milwaukee Fire Department Officials.

Chief T. A. Clancy, of the Milwaukee (Wis.) fire department, has chosen the Palmer & Singer for responding to alarms, and the Mitchell touring car, purchased by the city two years ago, will be used by the first assistant chief. The Palmer & Singer is a six cylinder, 60-90 horse power touring car, of five passenger capacity, and tests in Milwaukee brought out a speed of 63 miles an hour. The car cost \$4,347, not quite up to the appropriation of \$4,500 made by the Milwaukee Common Council. Every assistant chief in Milwaukee will be furnished with an automobile in order.

#### Commercial Notes.

The city of Portland, Ore., has purchased a Chalmers-Detroit automobile for the use of City Health Officer Wheeler.

The city of Tacoma, Wash., has appropriated \$5,000 for an automobile hose wagon for the fire department, and \$2,500 for an automobile for the fire chief.

An automobile route has been established between Enumclaw and Auburn, Wash., comprising a portion of the distance between Tacoma and Seattle. The promoters of the enterprise are Dr. Smith, S. L. Sorensen and P. Kulberg.

The city of Augusta, Ga., has accepted the motor fire wagons furnished it by the Webb Motor Fire Apparatus Company, of Vincennes, Ind.

An automobile ambulance will be provided for the use of the sheriff's office at Milwaukee, Wis. The sheriff already has a touring car for the use of deputies, but finds an ambulance just as necessary.

Councilman A. J. Stoddard, of Seattle, Wash., has introduced a bill for the appropriation by the city council of a sufficient sum to properly letter all automobiles owned by the city. In this way it is hoped to put a stop to their illegal use for other purposes.

A motor propelled ambulance has been placed in service in Dallas, Tex. It was constructed in the Gallaway garage and Brooks carriage shop in Dallas. A second ambulance of improved construction is at present being built there, which will be used as a private ambulance by the Taxicab Company, and will answer calls for the sanitariums and for physicians.

There are now twenty-six automobiles in use by the various departments of the Boston city government. The police and fire departments have six cars each, the street cleaning department has three, the water and bath departments have two each, while the building, engineering, hospital, park, public grounds and schoolhouse departments get along with a single vehicle each.

An automobile service is at present being established from Lubbock to Emma and Crosbyton in the panhandle of Texas. At Crosbyton the line will connect to Floydada by way of Dickens, and also with the new town of Spur. Another automobile line has just been completed from Lubbock to Brownfield, which will probably be extended by way of Monument, N. M., to Barstow, Tex. Another line will soon be

established between Lubbock, Tahoka, Post, Fluvana and Lamesa.

#### Oscar Lear Company May Be Sold.

A number of parties have been negotiating for the plant of the Oscar Lear Automobile Company, Springfield, Ohio, which company has been in the hands of a receiver for over a year. Among those who have been mentioned as endeavoring to get control of the plant are E. S. Kelly, of Springfield, and the General Motors Company, the latter of which are reported to have purchased the stock of W. A. Miller, of Columbus, and to hold an option on that of Oscar Lear.

#### Insurance Rates Rising.

Writers of automobile insurance throughout Illinois, especially in the Chicago district, are trying to agree to raise the premium from 2 to 2½ per cent. Thus far the Chicago agencies have not been able to secure the advance, although it is becoming general throughout the State.

#### Road Makers' Convention.

Arrangements have been practically completed for the largest good roads congress ever held in America, which will take place at Columbus, Ohio, October 26 to 29, when the American Road Makers' Association. the Ohio Good Roads Federation and the Ohio County Commissioners' Association hold a joint meeting. It is expected that 3,500 or more delegates will be in attendance from every section of the country. One of the features of the meeting will be the attendance of special delegates from most of the States in the Union. Governor Harmon has named delegates for Ohio. To aid in the entertainment the Franklin County Good Roads Association has been organized, with a preliminary membership of 130. E. A. Peters is president and William M. Maize secretary. Special committees have been named to look after the entertainment of the delegates.

AUTOCAR MOTOR MAIL WAGON, FIVE OF WHICH ARE IN USE IN PHILADELPHIA.

#### The Brighton Beach Twenty-four Hour Race.

While the third and final twenty-four hour race of the season held by the Metro-politan Racing Association at Brighton Beach on last Saturday may not have been all that could be desired from a financial standpoint, from the viewpoint of racing it certainly was a great success. In the first place the track was in such fine condition that not only was the usual recess for the repair of the track deemed unnecessary, but the competition was so keen that

the records of the track for every hour except the sixteenth and seventeenth were badly shattered. This was, perhaps, due as much to the exceptional care taken with the lighting arrangements as to the condition of the track. The honors of the day went to a Lozier car driven by Mulford and Patschke, which covered 1,196 miles, or 19 miles more than the former record of 1,177 miles established by

George Robertson in a Simplex. To make the Lozier victory complete second place was secured by the other entry of that make, driven by Cobe and Seymour, which covered 1,169 miles. At the starting line were lined up nine of the eleven original entries, two of which had been withdrawn. The starters were as follows:

	Machine.	Drivers.	Drivers.				
1.	Withdraw Palmer &	n, Singer Howard, Knipper	a				
	2000	Lescault.					

. Withdrawn.

8. Rainier ......Owen and Bowers.
9. Rainier ......Dearborn, Disbrow and Lund,
10. Marion ......Strang, James and Plan-

agan.

The cars were started promptly at 8 o'clock by Dr. Cook, the Arctic explorer, and although at times the race seemed to be assured to one car or another, there was always a struggle for position, and at no time did the race lack interest. At the start the Buicks made the pace, and keeping close together steadily increased their lead

LOZIER NO. 3, WINNER OF THE RACE.

on the field. In the second hour No. 6 Buick had tire trouble and No. 5 gained a lead of about 3 miles, but at the end of the fourth hour Chevrolet, the driver of No. 6, regained this lead, and held it till the thirteenth hour, when, owing to a broken rear axle, he dropped back to sixth place. This accident cost him about an hour, and he immediately tried to make it up, but evidently the accident had weakened the machine, and he was forced to retire in the seventeenth hour with a broken steering knuckle, having covered in all 764 miles.

The first serious trouble happened during the fifth hour to the Palmer & Singer, which broke the right front steering wheel spindle, which caused the wheel to fly of and strike a woman, fortunately without seriously injuring her. This caused a delay of about two hours and a half, and put the car in the last position. In the tenth hour this car was forced to retire, having burned out a connecting rod bearing. Toward the end of the eleventh hour the Rainier No. 8, which up to that time had been fourth, while going down the home stretch burst a tire, ran into the infield fence and turned turtle. The mechanic and driver both

jumped, the former being only slightly injured, while the driver, Bowers, had his skull fractured.

From that time on very few changes occurred in the relative standing of the cars. The Logier No. 4 led up to the seventeenth hour, but at this point a steering knuckle broke and the machine plunged through the infield fence. Furtunately, however, no further damage was done, and after about a quarter of an hour

the machine was going again, but it had lost the lead to its team mate, No. 3. Just before this happened Seymour, who at the time was driving No. 4, was closely pursuing the Marion into the home stretch. In rounding the turn the Marion skidded and turned completely around. Only by a quick turn of the steering wheel was Seymour able to avoid a bad accident. It is, of course, barely possible that this sudden strain may have been more or less directly the cause of the accident which happened only five minutes or so later. This seventeenth hour was somewhat eventful, for the Matheson, with Basle driving, also broke a steering gear and plunged through the infield fence.

GENERAL VIEW OF CAMPS AT BRIGHTON BEACH

However, none of the contestants was injured and the machine was again in the running after about three-quarters of an hour, with its relative position still unchanged. During the last hour of the race the motor of this car slowed down and finally seized, so that the machine did not finish.

There was a special prize offered for the greatest number of miles during the last hour made by any car which had started. It was announced that this was won by the winning Lozier No. 3. The two leading cars were equipped with Diamond tires.

The finishes of the race and the number of miles covered are given in the following table:

ositio	n. N	ło.	Car.					Miles.
1.	No.	3	Lozier		 	 		1,196
2.	No.	4	Lozier		 	 		1,169
3.	No.	9	Rainier	٠.	 	 		1,115
4-	No.	5	Buick		 	 		1,064
5.	No.	10	Marion		 	 	٠.	904

The arrangements were remarkably good from the point of view of the spectator. The score boards were large and could be read from the grand stand without the aid of an opera glass. The boards were numbered from right to left. The camps were in the infield, extending from the beginning of the home stretch to the score boards. They were also placed numerically from right to left and prominently numbered. It was thus easy to see at a glance what cars were at any time laid up for repairs or replenishments.

A rather remarkable feature of the race was the large number of steering gear breaks, and the fact that none of the contestants was injured thereby. It is probable that in high speed track racing much greater continuous strain is put on these parts than in any other class of work, road racing not excepted.

#### The Louisville Reliability Contest.

The Louisville (Ky.) A. C. held a two days' reliability run from Louisville to Winchester, Ky., and back on October 8 and 9. The cars started from Louisville at 6 o'clock a. m. and reached Winchester the same evening shortly after 6 o'clock, they being met about 5 miles out of the city by a delegation of the Winchester A. C. During the evening an informal luncheon was given at the Elks Hall by the Winchester Club to the tourists. The contesting cars were divided into five classes according to selling price, and the running time was different for each class.

On Saturday the return run to Louisville was made. Upon the return to Louisville all the cars were subjected to an examination by a technical committee. It was found that the Rambler No. 3, entered and driven by Prince Wells, and the Rambler No. 12, entered by August Ropke, both came into the end control with perfect scores and tied for first honors in the reliability contest. The tie will probably be run off at a future date.

The cup offered for the car showing the createst economy in the consumption of

gasoline, oil and water was won by Ira S. Barnett (Cadillac No. 1). The Prince Wells prize for the Rambler making the best showing was won by Harry Rooke. The Maxwell trophy donated by the Maxwell-Clark Motor Car Company and the Buick Trophy offered by the Hubert Levi Auto Company were won by Mrs. Harvey Myers, of Covington, Ky., who drove a Buick. The Cadillac prize offered by the Kentucky Automobile Company was awarded to R. E. Gregory. The C. C. Stoll prize. for the least amount of oil consumed during the trip, was also awarded to R. E. Gregory. The Kentucky Consumers Oil Company's prize, consisting of 25 pounds of non-fluid oil, was awarded to Mrs. Harvey Myers. The Owners' trophy offered by the Louisville Automobile Club for the best showing in the reliability run was awarded to Bertram Strauss (Rambler)

## Conditions of Vanderbilt Race

The supervisors of Nassau County, New York, granted their permission for the running of the Vanderbilt Cup race under certain conditions, among which are the following: The race must be run between the hours of 5 a. m. and 5 p. m. on October 30. The contestants have the privilege of practicing on the course between the hours of 5 and 8 a. m. daily from the time of acceptance of conditions made by the board of supervisors. The Motor Cups Holding Company must sprinkle the Massapequa road with oil, repair the old country road and make it safe; bank the turns on the roads with sand a foot high on the outer edges; guard and police the course during the practice periods and on the day of the race, and as is deemed necessary by the county sheriff; it must also put up a bond of \$100,000 to indemnify the county supervisors and sheriff against any damage suits that may grow out of accidents; it must further deposit a sum of \$500 with the county treasurer for the repair of the roads after the race. It is further stipulated that if any entrants are arrested and convicted of speeding during the practice periods they and their machines must be disqualified from taking part in the race.

#### Vanderbilt Cup Race News.

At the time of going to press twenty entries had been received for the Vanderbilt Cup and concurrent races which are to be held on October 30. Of these, thirteen entries are for the Vanderbilt race, five for the Massapequa trophy race, and two for the Wheatley Hills trophy race. The entries will close on October 25, and it is expected that at least thirty cars will be entered. Seven entries were received on Monday, including a Buick, to be driven by Louis Chevrolet, three Maxwells, entered by Carl Kelsey, two Marmons, and an American Roadster. The first cars to put in an appearance on the track for practicing were two Chalmers-Detroits, which

are to be driven by William Knipper and Joe Matson, respectively.

There has been some grumbling among the drivers over the fact that no cash prizes are offered to drivers in the contest for the Vanderbilt Cup, while \$1,000 cash prizes are offered to the winning drivers in the contests for the Wheatley Hills and Massapequa trophies. It is argued that inasmuch as the entry fee for the Vanderbilt Cup race is twice that for the two minor events, a cash prize might well have been offered to drivers in the more important event. The course will be open for practice every morning from 5 to 8 o'clock, until the day of the race. The timing and scoring are to be attended to by the New York Timers Club, with whom arrangements have been made by the Motor Cups Holding Company.

#### Automobiles in Brazil.

The effect of the prevailing depression on the imports of automobiles into Brazil is shown in the following report from Consul General George E. Anderson, of Rio de Janeiro:

"The general depression which has been manifest in most lines of the import trade in Brazil during the past few years has been very marked in the imports of automobiles. The imports in 1907 amounted to 363 machines, valued at \$663,144, and in 1908 to 297, valued at \$551,682. For the first six months of 1909 the imports amounted to only 118, or at the rate of 236 machines for the year, a loss of about 20 per cent. over last year. The machines imported from the United States in 1907 numbered 54, valued at \$89,215; in 1908, 43, valued at \$71,441, and only 14 for the first six months of 1909. Of the total of 207 automobiles imported from all countries in 1908, France furnished 139, Italy 51, the United States 43, Great Britain 36, Germany 20, and other countries 8. In the first six months of 1909 the total was composed of 52 from France, 20 from Italy, 14 from the United States, 14 from Germany, 6 from Great Britain, and 12 from other countries.

"The relative gain in the imports from Germany during the six months ended June 30, 1909, is due to good agency work in the face of a depressed market. Dealers say that the German machines, which are largely for trucking work, are sold at low prices, all things considered, and that they represent efforts to keep factories going in the face of unfavorable conditions rather than profitable business.

"For passenger purposes the favorite cars still seem to be those from France and Italy. This, however, is largely due to superior agency and repair shop arrangements. The American cars here are well liked, on the whole, and the sale of the higher grade American cars, particularly, could be increased if the agents here were prepared to properly care for them after they are sold. "General trade conditions in Brazil are gradually recovering."

## Misstatement Does Not Invalidate Insurance Policy.

A suit to recover from an insurance company under an automobile insurance policy was decided in the Common Pleas Court in Baltimore, Md., on October 8, in favor of the plaintiff. The suit was brought by William P. Cummings against the British and Foreign Marine Insurance Company, Ltd., of Liverpool. According to the testimony Mr. Cummings, through his private secretary, purchased a touring car and insured with the company for \$1,500, paying a premium of \$60. In the application for the insurance the automobile is stated to be a 1007 car. No. 2,048, and Mr. Cummings' secretary testified that this information was given him by the man from whom he purchased the car. The machine was kept in a garage by Mr. Cummings from the time of the purchase until April 24 last, when it was destroyed by fire while being used by Mr. Cummings'

The insurance company raised the point that the automobile was a 1906 instead of a 1907 model, and that they would not have insured a 1906 car for the same amount, but would have charged a greater premium, and that the value of the car had been greatly overestimated. The company alleged that the policy was void by reason of the misrepresentations in the application for insurance. Counsel for complainant argued that inasmuch as the policy contained no clause declaring it to be void in the event of incorrect representations in the application for insurance, the court could not construe a representation to be a warranty unless the intention to create a warranty be expressed upon the insurance policy or the application, and that the representations, even if incorrect, were not such as to vitiate the policy, but would only permit the excess premium that would have been charged for insuring a 1906 car to be pleaded as a set-off, and as no plea of set-off was filed in the case evidence along these lines should not be permitted.

The court refused all the instructions asked by the company and granted those asked by attorney for complainant. The jury promptly brought in a verdict for the full amount of the policy, with interest to date, less the present value of the car, as shown by the testimony, the verdict being for \$1.430.

## Auto Liability Insurance Void in Iowa.

Attorney General Byers of Iowa has upheld the State Insurance Department in its ruling that risk companies cannot insure automobile owners against liability for ac-

cidents caused by their machines, except when the person injured is an employee of the owner.

The Attorney General submitted his opinion at the request of State Auditor Bleakly. He holds with the Auditor that the laws of Iowa give insurance companies no authority to write such insurance. Such an interpretation of the law will work no hardship on automobile owners, says Mr. Byers, because its only effect will be to make them more careful in operating their machines.

## Wisconsin Oil Inspection Law Sustained.

The Wisconsin oil inspection law has been sustained in the Circuit Court in Milwaukee, after a hard contest was made against it by the Wadhams Oil and Grease Company, of Milwaukee, which objected to paying a fee of 10 cents per barrel for inspection services. The case will go to the Supreme Court. A suit brought against Thomas B. Jeffery & Co., of Kenosha, Wis., to enforce the law, has been dismissed. The law covers the inspection of lubricants, gasoline and oils of various kinds. E. L. Tracy is the State inspector.

#### Jacksonville Taxes Taxicabs.

The city council of Jacksonville, Fla., has passed an ordinance requiring all public service automobiles to be licensed, and imposing a license fee. The license fees for the different classes of vehicles are as follows:

Autos and taxicabs up to five passengers.. \$12.50 Autos and taxicabs, six to ten passengers.. 50.00 Sightseeing cars, ten to fifteen passengers.. 100.00 Sightseeing cars, fifteen to twenty passen-

Sightseeing cars, over twenty passengers... 200.00

The ordinance went into effect on Octo-

#### Injunction in Tire Litigation.

Judge Slater, at Cincinnati, on October II, granted to the complainant in the case of the Goodyear Tire and Rubber Company vs. the Rubber Tire and Wheel Company and Consolidated Rubber Tire Company, an injunction pendente lite, enjoining the latter from instituting and maintaining any action against any of complainant's customers who buy and handle, use or sell its patented rubber tire.

## Owners Responsible for Joy Riding Accidents in Ohio.

A joy ride in a motor car owned by R. G. Wallace and F. C. Gillett cost the owners \$150 recently, in a suit before Justice Bostwick in Columbus, Ohio, who awarded damages in that amount to Ray Coulter, who was injured in the mad ride. The car was driven by a friend of the owners, but the action was brought against the owners under the section of the Ohio law which establishes the financial responsibility in joy riding cases.

## Wisconsin Signboard Law to Be Enforced.

Town boards in Wisconsin are not hastening to comply with a new law requiring them to erect and maintain suitable guide posts in the main traveled highways. The law gives them until November 1 to comply, and if posts are not erected within a reasonable time the Wisconsin State A. A. intends to compel enforcement of the law.

#### Legal Notes.

The upper house of the Kansas City Council has been considering an ordinance which provides that no garage or stable shall be built within 25 feet of a residence not owned by the party putting up the building, and that buildings of this class must be set 50 feet back from the sidewalk. Objection was made to the inclusion of garages in the provisions of the ordinance, as garages are kept clean and are absolutely inoffensive. The ordinance was referred to a committee.

A protest has been lodged with the Board of Estimate of Baltimore, Md., against the installation of a 200 gallon gasoline tank in connection with the new garage on Mt. Royal avenue and McMechen street by residents of the neighborhood. They claim that the installation of this tank would endanger life and property in the vicinity. The matter was placed in the hands of Building Inspector Preston and Chief Horton, of the fire department, who will report to the board on October 26.

#### Good Roads Convention and Race Meeting in New Orleans.

A model road is being constructed by the State of Louisiana from New Orleans to Baton Rouge, the State capital. It is stated that in the city of New Orleans there is at present considerable activity in the way of street improvements and the construction of new boulevards. To arouse further interest in the subject, a good roads convention has been called by Governor Sanders of Louisiana and the New Orleans Progressive Union, to take place in New Orleans, on November 19. The convention is to be followed by a track race on November 20-21, under the auspices of the New Orleans A. C. The events include a 5 mile race for cars of 301 to 450 cubic inches piston displacement, a 50 mile race for five classes of cars according to the A. A. A. classification. a six hour race for the same cars, and two 5 mile and two 10 mile races for local chauffeurs and amateurs.

#### Business Trouble.

A petition in bankruptcy has been filed against the Stevens-Britton-Maure Company, manufacturers' agent for automobile supplies, machinery, etc., at 1783 Broadway, New York, by these creditors: Albert F. Britton, \$1,800; Walter W. Robinson, \$6: Benjamin M. Asch, \$6.

## **Exhibitors at Grand Central Palace**

Final diagrams for the Tenth International Automobile Show, which opens New Year's Eve in Grand Central Palace. New York, under management of the American Motor Car Manufacturers' Association, show seventy-two makers of American cars and fifteen importers of foreign cars with six additional American cars on the waiting list, making a total of ninety-three makers of automobiles. This is by far the greatest number of automobile concerns ever brought together in any show held in New York.

Members of the Motor and Accessory Manufacturers totalling 110 will draw for space for the Palace Show on October 22. These, together with 104 accessory concerns not affiliated with the M. & A. M. and twelve on the waiting list, bring the grand total up to 319 exhibitors in the Palace Show. Following is a list of the motor car exhibitors who have been allotted space in the Palace Show:

#### AMERICAN CARS.

American Motor Car Co., Indianapolis, Ind. American Motor Truck Co., Lockport, N. Y. Allen-Kingston Motor Car Co., New York, N. Y. Atlas Motor Car Co., Springfield, Mass. Austin Automobile Co., Grand Rapids, Mich. B. C. K. Motor Car Co., York, Pa. Bartholomew Co., Peoria, Ill. Black Manufacturing Co., Chicago, Ill. Brush Runabout Co., Detroit, Mich. Buckeye Manufacturing Co., Anderson, Ind. Cartercar Co., Pontiac, Mich.
Carter Motor Car Corp., Washington, D. C.
Chadwick Engineering Works, Pottstown, Pa. Chase Motor Truck Co., Syracuse, N. Y. Cameron Car Co., Beverly, Mass. Coates-Goshen Co., Goshen, N. Y. Columbus Buggy Co., Columbus, Ohio. Crawford Automobile Co., Hagerstown, Md. Dayton Motor Car Co., Dayton, Ohio. Demotear Sales Co., Detroit, Mich. Empire Motor Car Co., Indianapolis, Ind. Fal Motor Co., Chicago, Ill. Ford Motor Co., Detroit, Mich. Gaeth Automobile Co., Cleveland, Ohio. Grabowsky Power Wagon Co., Detroit, Mich. Gramm-Logan Motor Car Co., Bowling Green, Ohio. Hart-Kraft Motor Co., York, Pa. Holsman Automobile Co., Chicago, Ill. Houpt, Harry S., Manufacturing Co., New York, N. Y. Hupp Motor Car Co., Detroit, Mich. Interstate Automobile Co., Muncie, Ind. #### SECOND FLOOR.

S. F. Bowser & Co., Fort Wayne, Ind. Sprague Umbrella Co., Norwalk, Ohio. Herz & Co., 203 Lafayette street, New York. Never-Miss Spark Plug Co., Lansing, Mich. Leather Tire Goods Co., Niagara Falls, N. Y. Dow Tire Co., 2000 Broadway, New York. C. A. Shaler Co., Waupum, Wis. Randall-Faichney Co., Boston, Mass. Stromberg Motor Devices Co., Chicago, Ill. Dayton Rubber Manufacturing Co., Dayton, Ohio. High Wheel Auto Parts Co., Muncie, Ind. Lavalette & Co., 112 West Forty-second street, New York.

Adam Cook's Sons, 313 West street, New York.

#### Accessories,

Charles E. Miller, New York. Post & Lester, Hartford, Conn. Cloud-Stanford Co., Atlanta, Ga. Rutherford Rubber Co., Rutherford, N. J. Chicago Wind Shield Co., Chicago, Ill. W. F. Polson, Buffalo, N. Y. Vehicle Apron and Hood Co., Columbus, Ohio. Shipman Instrument Co., Sunbury, Pa. Ajax Trunk and Sample Case Co., New York. Emil Grossman Co., New York.

Motorcycles.

Hendee Manufacturing Co., Springfield, Mass. Aurora Automatic Machinery Co., Chicago, Ill. Consolidated Manufacturing Co., Toledo, Ohio. Excelsior Supply Co., Chicago, Ill. Greyhound Motor Works, Buffalo, N. Y. N. S. U. Motor Co., New York.
Milton W. Arrowood Co., Atlanta, Ga.

#### GARAGE ITEMS

Garage Firm Stops Tipping.

The day of the gratuity in the garage and shop of the Greer-Robbins Company, Mitchell agents in Los Angeles, is past. A customer desiring to have his car washed and polished well or speedily no longer is confronted by the open hand, besides the bill. The order against the tip has gone forth, and instant dismissal is the penalty for the acceptance of the unearned increment.

The firm's customers appreciate the innovation. When one of them offered the usual gratuity to the washer and the silver was refused, he gasped, examined the coin closely, and remarked that it was a perfectly good one, whereupon the washer explained that tips in this garage were a relic of the past. Three days later the man who could not get rid of his tip had the showroom of the building converted into a dining room, and invited the fourteen garage and shop employees to an eight course banquet, with all the necessary trimmings, to show his appreciation.

Indianapolis Auto Row.

By November 1 Indianapolis will have a new automobile row, when the Conduitt Building in North Delaware street is expected to be completed. The building is a one story brick structure, and has been divided into a number of rooms designed especially for automobile salesrooms. It is within a square of Massachusetts avenue, which for some years has been the centre for many automobile agencies. Companies that have leased quarters in the new building are Finch & Freeman, representing the Richmond, Auburn and Rider-Lewis; the Peck Motor Car Company, representing the Cadillac: the Conduitt Automobile Company, having the Knox agency, and the State Automobile Company, Indiana agents for the Oakland.

#### Isotta on the Pacific Coast.

The Motor Car Import Company, of Los Angeles, has closed a contract with the American representatives of the manufacturers of the Isotta-Fraschini car, and has obtained the agency for the product of Italy for the Pacific Coast States, where heretofore no foreign make was adequately represented. C. F. Fenner, formerly the agent for the White steamers in Southern California, is the head of the Import Company, which will also handle the Halladay line.

#### New Idea in Garage Valuation.

Tax Commissioner F. B. Schutz, of Milwaukee, is planning for what he terms an "all-year" valuation of automobile garages. He would not make assessments in the springtime of each year, when garages are well stocked, as is at present the practice. He believes that at that period demonstrators crowd the garages and that it is not fair to the agents and dealers to tax them on a temporary basis at a time when they get the "short" end of it.

#### Garage Notes.

NASHVILLE, TENN.—Howard Cregor & Co. will open a garage at 135 Third avenue.

IOI.A, KAN.—John T. Wood is building a one story brick automobile repair shop at Sycamore and Madison avenue.

NEWCOMB, N. Y.—Archer M. Huntington is constructing a stone garage at Arbutus Lake Preserve, to cost \$15,000.

RHINELANDER, WIS.—J. H. Morgan has plans for the establishment of an auto livery at 22 South Stevens street.

BUFFALO, N. Y.—Wm. J. Statler, of 202

Anderson place, is having plans drawns for the erection of a garage on Bidwell Parkway.

PORTLAND, ORE.—The Firestone automobile

PORTLAND, ORE.—The Firestone automobile agency has secured garage quarters with the Graham Motor Co. at Fifteen and Washington streets.

NEW BEDFORD, MASS.—Plans for the building of a 48x56 foot, one story cement block garage on Harrison street north of Hickory street, are in the hands of W. L. Sturtevant.

WATERBURY, CONN.—The Board of Safety has awarded a contract for the erection of a new garage for the police auto patrol to Bergen & Sons, that firm being the lowest bidder.

& Sons, that firm being the lowest bidder.

BAY CITY, MICH.—Peter Oswald has bought a building site on Walnut and Vermont streets, on which he will erect a garage building which will be completed for occupancy by February next.

MACOMB, ILL.—Ewing & Deems have closed a deal for the purchase of property on the east side of South Randolph street, on which they will erect a two story 50x120 feet fireproof garage.

KANSAS CITY, MO.—A permit has been granted to Mrs. Mary C. Wilder for the erection of an 80x160 foot two story garage at 922-926 East Fifteenth street. The estimated cost is \$20,000.

LOUISVILLE, KY.—Thomas King, who operated a livery stable on Guthrie street, has sold all his horses, and has remodeled his establishment into a spacious garage. He has taken the agency for the American Traveler.

agency for the American Traveler.

SAN ANTONIO, TEX.—Herman and Paul Eikel have organized the Eikel Auto Co. to handle the Jackson car. They have secured headquarters at 427 Main avenue. They hold the Jackson agency for the whole of southwestern Texas, and will establish sub-agencies.

CLEVELAND, OHIO.—The Barger Automobile Co. expect to move into their new garage and salesroom at 1632 Euclid avenue about November 1. In addition to offices and salesroom on the first floor a large repair shop will be established in the basement.

AUGUSTA, GA.—The Augusta Auto Garage and Supply Co. at a meeting held on October 6 elected the following officers: C. B. Garrett, president; Jos. H. Day, vice president, and Frank G. Bohler, secretary, treasurer and general manager. Fred Perroux will be manager of the mechanical department.

CHICAGO, ILL.—The E. R. Thomas Motor Co., of Buffalo, N. Y., has secured a fifteen year lease on the property at the northeast corner of Michigan avenue and Twenty-third street, and will erect a three story building at an estimated cost of \$75,000. The terms of the lease call for a rental approximating \$175,000.

rental approximating \$175,000.

NEW YORK, N. Y.—The garage of the Joseph Loughran Co. at 1170 Fifth avenue, between Ninety-eighth and Ninety-ninth streets, was destroyed by fire on October 14. Two chauffeurs were in the garage at the time the fire started, and it is stated that one of them knocked over a candle on the oil soaked floor, though it seems

rather strange that a candle should be used in a garage. The damage is estimated at \$20,000, and includes the value of four taxicabs which were ruined by the fire.

SPRINGFIELD, MO.—Rountree & Estes will open a garage in the new building nearing completion on South Jefferson street near Walnut street as soon as it is ready for occupancy. The new concern will have 100x100 feet of floor space.

GREEN BAY, WIS.—J. C. Zimmer and H. C. Malchow, of Oshkosh, have leased the auto and garage business formerly owned by Gotfredson Brothers on Jefferson street. The building is to be improved. It is their purpose to rebuild and paint cars, and part of the second story will be used for this purpose.

GRAND FORKS, N. DAK.—The Burgess-Whitcomb auto agency has been taken over by Beek & Florin, of Lakota, who have changed the name to the Dakota Auto Co. E. D. Hanson, who had charge of the mechanical department of the old concern, will continue in the same capacity with the new firm.

LOS ANGELES, CAL.—The firm of Miller & Williams has opened headquarters at 1140 South Olive street, and will handle the Pullman car. The firm consists of Roger H. Miller, who has been connected with the Tourist factory in Los Angeles for the past two years, and Geo. M. Williams, formerly a member of the firm of Rentou & Williams, auto dealers.

OMAHA, NEB.—A contract has been let for the erection of two brick garage buildings on the C. E. Perkins estate on Farnam street, between Nineteenth and Twentieth streets, at a cost of \$15,000. The building will be one story, with a total frontage of 97 feet. The Buick Automobile agency will occupy one of the buildings, and the Omaha Auto Co. the other.

ATLANTA, GA.—The Olds-Oakland Co. will occupy a garage building within a few months, for which the contract has just been let. The building will be 50x100 feet, four stories high, of reinforced concrete construction. It will be located at the corner of Cone and James streets, and the entire front of the first floor will be of glass, to permit of properly displaying the cars handled.

ALBANY, N. Y.—Plans for an addition to the Albany Garage Building on Howard street were filed this week in the Bureau of Buildings. The new structure will be 80x47 feet, four stores and basement. The garage will have two entrances, one on Howard street and one on William street. An elevator will render possible the storage of automobiles on the third and fourth floors.

TOLEDO, OHIO.—The Twenty-first Street Garage is to have an 80x220 addition to its present building. The rear portion of the new building will be two stories high, and will contain a large repair shop. The present garage will be given over entirely to display, storing and caring of cars. A. B. Hanson, who was formerly local sales manager for the Pope Motor Car Co., has been put in charge.

PITTSBURG, PA.—A new garage is to be crected at the corner of Grant boulevard and Craigh street, for which plans are now being drawn by E. A. Dyche. It is to be four stories on Craig street and two on the boulevard. The floor dimensions will be 135x136 feet, and the cost is estimated at \$50,000. The building will be ready for occupancy about March 1 next, and is to be used by a new taxicab company.

PITTSBURG, PA.—The Standard Automobile Co., Pittsburg, Pa., has let the contract for a four story steel and reinforced concrete garage building on Grant boulevard, which is to coat about \$135,000. It will have a frontage of 250 feet on Grant boulevard and 70 feet on Bellefield avenue. The building will have a gray brick and terra cotta exterior. It is to be finished by April 1, 1010. The first floor will contain the salesroom, tire department, garage and general offices. The second floor will be used as a stock and trinming department; the third floor will be given over to upholstering, wood working, paint

ing, etc., while on the fourth floor will be the toll, repair and blacksmithing departments.

CARLSBAD, N. M.—A \$6,000 garage is being erected for W. M. Kerr.

BARKER, N. Y.—E. R. Featherston is completing a two story garage on Quaker avenue.

ST. JOHNSBURY, VT.-F. S. Harriman will open a garage on Central street in the near future.

LORAIN, OHIO.—Dewey Moore will open a garage in the old Schnitzler Building on Tenth street.

FULTON, KY.—I. H. Read and C. E. Webb are considering the erection of a two story garage and salesroom.

CALUMET. MICH.—The Superior Motor Co., a new concern, has opened a garage and sales-room for the Buick.

COLUMBUS, OHIO.—The Price Implement Co., of Zanesville, Ohio, has added a line of automobiles to its stock.

MOORESTOWN, N. J.—The garage of Henry Pew was badly damaged by fire last week. The cause of the fire is unknown.

MINNEAPOLIS, MINN.—M. R. Waters & Sons have moved into their new garage at 1332 and 1334 Nicolet avenue, near Grafit street.

CLEVELAND, OHIO.—The Barger Automobile Co., Cadillac agents, are moving into their new garage and salesroom at 1628-1632 Euclid avenue.

BUFFALO, N. Y.—A permit has been granted to the Babcock Electric Carriage Co. for the erection of an addition to its garage on West Utica street.

DENVER, COL.—Fry & McGill are equipping an automobile repair shop in the rear of the Majestic Building. They will make a specialty of repairing lamps.

MINNEAPOLIS, MINN.—The Four Traction Motor Co., of Mankata, is to open a garage in this city at 33 Tenth street S. E. B. Pakers will be manager.

PITMAN, N. J.—Last week a fire broke out in French's garage, badly damaging the building and destroying a car owned by C. B. Tichenor, which was in the building.

DALLAS, TEX.—The Alamo Automobile Co.

DALLAS, TEX.—The Alamo Automobile Co. have opened a salesroom at 319 Commerce street, and will handle the Stoddard-Dayton line. J. J. Gorman is manager of the company.

SAN FRANCISCO, CAL.—A permit has been granted to Cuyler Lee for the erection of a three story concrete garage on the corner of Jackson street and Van Ness avenue, to cost \$60,000.

OMAHA, NEB.—The Mid-West Automobile Co., who handle the Cole "30," expect to locate shortly in a suitable garage on Nineteenth and Farnam streets. R. A. DeWitt is manager of the company.

KANSAS CITY. MO.—Work has been commenced on a two story 45x125 foot garage for the Rambler branch on Fifteenth and Harrison streets. The building will be ready for occupancy December 1.

COLUMBUS. OHIO. — The Maxwell-Briscoe Motor Co., of North Tarrytown, N. Y., have opened a distributing agency in a new building recently completed by John C. McCahran at 62 East Spring street, Columbus, Ohio.

VIRGINIA, MINN.—The Range Motor Co. have just purchased two lots 50x100 feet, on which they will erect a two story and basement fireproof garage. The new building will not be ready for occupancy before the early spring.

MINNEAPOLIS, MINN.—Walter H. Grower has bought the auto repair business of J. M. Murphy, located at 830 Hennepin avenue. Mr. Grower was formerly traveling expert for the Studebaker Automobile Co. at Chicago.

COLUMBUS, OHIO.—The garage of William F. Wagner at Massillon, Ohio, was damaged to the sum of \$5,000 by a fire October 13, which gutted the building. Firemen worked in a shower of sparks which fell on several barrels of gasoline.

GRAND FORKS, N. DAK.—F. H. Haviland has assumed the management of the Grand Forks branch of the Dakota Auto Co., who handle the Reo and E-M-F. The other members of the firm,

R. H. Beek and S. A. Floren, will reside at Dakota.

WASHINGTON, IA.—Lytle Brothers, a new firm, is to open a garage in the near future. In the meantime they will exhibit a line of Studebaker cars at the Frank Bell Carriage Works. In connection with the garage they expect to carry a full line of automobile supplies and accessories.

ESCANABA, MICH.—Thomas Richter, who has conducted a livery business for many years, has disposed of his horses and carriages, and will go into the automobile business. Plans have been drawn for a garage to occupy the site of his stables. He will handle several leading lines.

WAVERLEY, IA.—Clark & Mitchell are to open a garage in the Dawson Building on East Bremer avenue. Part of the building will be fitted up as a salesroom, where they will handle the Buick, Overland, Reo and Studebaker cars. Later on they will establish an auto livery service.

SYRACUSE, N. Y.—Melvin W. Kerr, manager of the Syracuse Buick branch, will resign on November 1 and become a member of the new Kerr-Doane Motor Co., who will handle the American Simplex and the Velie cars. The members of the new company, which is shortly to be incorporated, are Melvin W. Kerr, president; James Doane, secretary and treasurer, and Fred C. Beckwith.

PHILADELPHIA, PA.—A fire occurred in the garage of the Philadelphia and Merion Transit Co. on Sixty-third street and Columbia avenue last week, destroying the whole building and a large sightseeing automobile valued at \$4,500. Another machine of the same kind was saved. Boys playing with matches were seen nearby, and it is supposed that the fire was the result of their carelessness.

SALT LAKE CITY, UTAH.—Work has been commenced on a new brick garage to be built for Oscar and James Moyle on State street, south of the Utah Independent Telephone Co.'s Building. The new building, which will be 76½x247 feet, will consist of four stories and basement, and will be constructed so that three additional stories can be added. The estimated cost is \$40.000.

RUTLAND, VT.—L. H. McIntyre, L. A. Perkins, T. W. Maloney and others are organizing a company to take over the fireproof garage conducted by Burdick & Smith on Willow street, and the garage of L. A. Perkins & Co. on Strongs avenue. The Willow street garage will be used as a repair shop and showroom, and the Strongs avenue garage as a storeroom. The same line of cars that was handled by Mr. Perkins will be continued by the new company.

DENVER, COL.—The Studebaker Automobile

Co. has secured a lease on the new building which is to be erected by Charles Schleter on Cheyenne street, between Fifteenth and Sixteenth streets. The company will occupy the building as a sales-room, and not as a garage. It is to be equipped with electric elevators, and will have a plate glass front. The property was bought by Mr. Schleter for \$50,000, and the new building, which is to be two stories high and have walls of sufficient strength to admit of adding two stories later on, will cost \$25,000.

UTICA, N. Y.—George H. Norris, secretary and treasurer, and T. Harvey Ferris and C. H. Norris, directors, have resigned from the Utica Motor Car Co., 333-337 Bleecker street. George H. Norris has been elected vice president, and Hon. James S. Sherman and Sherrill Sherman have been elected directors. George H. Norris will in future devote his entire attention to the Syracuse branch of the company, known as the Genesee Motor Car Co., of which he is president. The Utica Motor Car Co. handles the Peerless, Cadillac and the Stevens-Duryca.

NEW YORK CITY.—Harold W. Bush and Willard M. Lyon, proprietors of a garage at 415 West 150th street, were held last week in the Harlem Police Court by Magistrate Krotel for examination on the charge of maintaining a nuisance. Some of the immediate residents of the neighborhood complained that they had to move because they could not get a decent night's

sleep, and J. C. Tierney, who owns an apartment house adjoining the garage, testified that he had lost three tenants because of the constant noise of the machines during the night.

AUBURN, ME.—Jonas Edwards & Son have the contract to build a large garage on Union street.

ELDORA, IA.—J. H. Hadley will soon erect a garage on the property lately purchased by him on Marion street.

BINGHAMTON, N. Y.—Work has been begun on a new concrete garage for B. W. Livingston & Son on Baldwin street.

BAKER CITY, ORE.—A. E. Tunnecliffe and W. A. Halliday have formed a partnership, and will handle the Hudson cars.

NEWARK, N. J.—The Newark Auto and Engineering Co. will build a \$6,000 garage and salesroom at 316 and 318 Broad street.

RUTLAND, VT.—W. C. Landon & Co. will soon begin the work of converting two stores in the Duffy-Chaffee block on Evelyn street into a garage.

OMAHA, NEB.—Chas. Merz, of Indianapolis, and H. E. Wilcox, of Casey, Ill., are to open a garage on Farnum street, between Twenty-fourth and Twenty-fifth streets.

PHILADELPHIA, PA.—Howard L. Haines has let the contract to build a 65x154 feet, one story stone and brick garage on the south side of Spring Garden street west of Twenty-second street. The approximate cost is said to be \$10,900.

#### New Agencies.

Utica, N. Y.—Davis & Clark, Oldsmobile.
Los Angeles, Cal.—C. C. Slaughter, Stearns.
Atlants, Ga.—Interstate Sales Co., Interstate.
Wausau, Wis.—L. H. Hall, Chalmers-Detroit.
Calumet, Mich.—Wieder Harness Co., Maxwell.
Syracuse, N. Y.—Willis & Van Brunt, Oakand.

Detroit, Mich.-J. B. McIntosh Auto Co., Lambert.

Winston-Salem, N. C .- The Motor Co., Stude-baker.

Pittsburg, Pa.—McAlister Motor Car Co., Cadillac.

Brooklyn, N. Y.—C. T. Silver, 62 Flatbush avenue, Overland.

Walla Walla, Wash.—J. H. and M. H. Paxton, Chalmers-Detroit.

Grand Forks, N. Dak.—The Dakota Auto Co., Reo and E-M-F.

Detroit, Mich.—Overland Sales Co., 295 Jefferson avenue, Overland.
Syracuse, N. Y.—Fred A. Marshall & Son, 231

Jefferson street, Hupmobile.

Los Angeles, Cal.—Motor Car Import Co.,

Isotta-Fraschini and Halliday. Kansas City, Mo.—The E. R. Hunnewell Motor

Car Co., 3816 Main street, Lozier.
Portland, Ore.—The White Motor Co. of Ore-

gon, White steam and gasoline cars.

Binghamton, N. Y.—Chenango Motor Sales
Co., Overland, Marion and Speedwell.

Minneapolis, Minn.—La Crosse Implement Co. (and automobiles), Imperial and Deal.

Cleveland, Ohio.—Euclid Auto Sales Co., Fire-stone-Columbus and Columbus Electric.

Denver Col.—Report & Williams 1889 Clerk

Denver, Col.—Bennett & Williams, 1530 Clarkson street, Palmer-Singer and Simplex.

Duluth, Minn.—The Russell Motor Co. (embracing Wisconsin, Minnesota and upper Michigan), Fal.

Brooklyn, N. Y.—Bishop, McCormick & Bishop, 20 Halsey street, Ford. (For the whole of Long Island.)

New York, N. Y.—Imperial Motor Vehicle Co., 212 West Seventy-sixth street (and surrounding territory), Grout.

Calumet, Mich .-

H. P. Clauson, Studebaker, E-M-F.

The Michigan Garage Co., Chalmers-Detroit. Portland, Ore.—

Ballou & Wright, Indiana.

Thompson-Cuthbert Motor Co., Speedwell. D. M. Smith, Packard.

Neate & McArthur, Locomobile and Oakland. Fred Gumpert, Regal and California Tourist.

In Enid, Okla., there are now 115 automobiles. The city levies a tax of \$2 per year on each car.

The Ohio Electric Car Company, recently organized at Toledo, will have their office and works at the Milburn Wagon Company plant.

The Prest-O-Lite Company, of Indianapolis, have established a branch in Minneapolis, at 109 Tenth street South, in charge of V. M. Heeth.

The Simplex Automobile Company call attention to the fact that the car which won the Fairmount Park race is the Simplex made in New York city.

The Automobile Dealers' Association of Los Angeles, Cal., which held a show in February last, has decided to hold another one the last half of December.

The I. H. C. motor buggies of the International Harvester Company will in future be manufactured in the plant of the Buckeye Mower and Reaper Company, Akron. Ohio.

The Brush Runabout Company, of Detroit, have reduced the price of their little single cylinder runabout to \$485, and decided on an output of 10,000 for the coming season.

The Phoenix Auto Supply Company have opened a branch in Kansas City at 2005 East Fifteenth street, in charge of Mr. Thayer, Western distributor for the Stepney spare wheel.

The annual convention of branch managers of the Buick Motor Company was held at Flint, Mich., last week. About thirty representatives of the company from all parts of the country attended.

A. P. Heney, of the Heney Auto Company, Aberdeen, S. Dak., has sold the business to Geo. F. Spaulding, of Minneapolis. Mr. Spaulding will have the agency for Halladay cars in South Dakota.

The third annual show of the San Francisco dealers was opened in the Emporium Building on October 16, and will continue during this entire week. The show will conclude on Saturday with the Alameda and Portola road race.

The General Motors Company is reported to have purchased the Jackson-Church-Wilcox plant in Saginaw, Mich. The latter company manufactures automobile parts, and recently increased its capital stock to \$60,000. A new factory building was recently completed.

The Rae Electric Vehicle Company, of which H. K. Parkman is president and H. C. Welch, of Boston, treasurer, are planning to locate in Charlestown, Vt., if \$40,000 of the company's capital stock of \$250,000 can be placed there. The company claims to have an electric automobile that

will travel from 125 to 150 miles on one charge.

The Diamond Rubber Company, of Akron, Ohio, has ordered a huge power unit from the Allis-Chalmers Company, of Milwaukee. It consists of a steam turbine of 1,250 kilowatt capacity for power for individual motors.

The Broc Carriage Company, of Cleveland, Ohio, will not make any changes in their electric model for 1910, except an increase in the wheel base to 80 inches. The company plans to increase its capital stock by \$50,000 to enable it to conduct its business on an enlarged scale.

The Taxicab and Automobile Company, which was recently organized in Salt Lake City, Utah, have secured the agency for the Cartercar, and plan to have twenty-five taxicabs of that make in operation in the near future. They have also secured the agency for the Thor motorcycle.

F. Kaplan was elected president of the reorganized E.-Z. Auto Go-Cart Company, of Monroe, Wis. D. S. Klafter, of Chicago, was elected vice president; George Thorpe, Monroe, secretary, and Louis Kohli, Monroe, treasurer. The plant was recently enlarged and removed from Beloit, Wis.

A newly organized co-operative association of automobile owners in Battle Creek, Mich., has made a bid of \$1,400 for the assets of the defunct American Motor and Cycle Company of that city, which bid will probably be accepted. The claims of creditors against the company amount to \$10,-857.05.

C. P. Kimball & Co., of Chicago, manufacturers of vehicle bodies, whose present plant is located on the corner of Michigan boulevard and Gorman court, have bought a property at Michigan boulevard and Thirty-ninth street for \$77,500, and will immediately begin the erection of a modern body factory.

J. McA. Johnson has secured control of the Kinsler-Bennett Company, of Hartford, Conn., and has been elected president and treasurer of the concern. The other officers of the firm are G. B. Kinsler, general manager, and Shiras Morris, secretary. The company manufactures universal joints and other auto parts.

Hugh Chalmers, president of the Chalmers-Detroit Motor Company, who gave a lecture on salesmanship before the City Club of Boston last spring, has accepted an invitation to speak at the retail trade dinner of the Boston Chamber of Commerce, which will be held at the Hotel Somerset on October 28.

The Dallas (Tex.) Automobile Dealers' Association are holding their first annual automobile show in the armory, October 18 to 30. Two street parades are features of the show, one being a trade parade and the other a parade for private owners. Prizes for the best decorated cars are offered in both of the parades.

The Pierce Motor Company, of Racine, Wis, which recently increased its capitalization to \$300,000 in order to enter the

automobile manufacturing field more extensively, will not become a unit of the General Motors Company as reported. Officers deny the reported action.

Automobile dealers and private owners gave a sociability run from Indianapolis to French Lick on October 16. Twenty cars made the run and a silver cup was awarded to the driver arriving at the control closest to a secret schedule. A hill climb was held at French Lick, Saturday afternoon, the prize being a silver cup given by Thomas Taggart.

The Irvin Manufacturing Company, Indianapolis, manufacturers of automobile tops, have begun the erection of a factory building in that city. It will be located in McCarty street, near Capitol avenue, and will be a two story brick structure, 56x140 feet. The building will cost \$14,000. The company is now located in the Industrial Building.

The Washington, D. C., dealers have appointed a show committee, with Chas. E. Miller, of Charles E. Miller & Brother, as chairman, and have decided to hold a show in Convention Hall during the week of January 24, immediately following the Madison Square Garden Show in New York. There will be 28,000 square feet of floor space available, and an elaborate scheme of decoration is contemplated.

The Great Southern Automobile Company is being organized in Birmingham. Ala., with a capital stock of \$100,000 and the following officers: E. F. Enslen, president; Ike Adler, vice president; John J. Kyser, secretary and treasurer, and E. F. Enslen, Jr., general manager. The new company have secured a property formerly used as a cotton mill, and will engage in the manufacture and repair of automobiles.

The H. H. Franklin Manufacturing Company, of Syracuse, N. Y., is now making and marketing its cars on a schedule fixed at the beginning of the season. The arrangement permits the purchaser to contract for a delivery date. Inspection of the schedule shows him on what date the car will be turned out at the factory and shipped to him. The dealer sells a certain automobile for delivery at a specified time just as if he had the machine complete and in his salesroom.

The Rauch & Lang Carriage Company, electric vehicle manufacturers, of Cleveland. Ohio, have just completed a two story extension of their machine shop on West Twenty-second street. The building is of brick, with a saw tooth roof, and measures 60x112 feet. Two other factory buildings, each about 60x112 and four stories high, are in course of erection. The top floor of one of these buildings is to be provided with a saw tooth roof, and will be used as a varnishing room.

The Los Angeles Motor Racing Association have leased Ascot Park, which is said to be one of the best equipped mile tracks in the country. They have already begun extensive alterations. Negotiations are being conducted with the Warner Instru-

ment Company regarding the use of their automatic timing instrument in timing the races on this track.

Ground for the new factory buildings of the Fiat Automobile Company, at Poughkeepsie, N. Y., was broken on October 11.

It is reported from Macon, Ga., that H. K. Burns, T. O. Parker and J. A. Smith will incorporate the Burns Motor Car Company with a capital stock of \$10,000.

William H. Durphy, sales manager of the Chase Motor Truck Company, of Syracuse, N. Y., was in Des Moines, Ia., the past week with the object of establishing an agency there.

The capital stock of the Phannstiel Electrical Laboratory, North Chicago, Ill., has been increased from \$30,000 to \$50,000, and additional machinery will be installed to push a magneto developed by Mr. Phannstiel

Walter J. Allen, 3 West Forty-fourth street, New York, will market a new car to be known as the Allen-Kingston, Jr., which is to be manufactured by the G. J. G. Motor Car Company, of White Plains, N. Y.

George Robertson, driving a Simplex car, covered 5 miles in 5m. 37s. on the Point Breeze (N. J.) race track on last Saturday afternoon in a race with L. J. Bergdoll and Willie Houpt, both in Thomas cars. In a run against time Robertson drove one mile in 1m. 5s.

The Benz Auto Import Company of New York have received a cable announcing that Hemery, driving a Benz car, established another world's record at Brussels by driving a kilometer from a standing start in 31 1-5s. The former record was 32 2-5s., and was held by a Mercedes.

The Rainier Motor Company, of Saginaw, Mich., plan to market 500 large cars during the 1910 season, of which 200 have been assigned to New York, while the remainder will be marketed through new agencies now being established in various large cities. It is stated that the new model will be out next month.

The Gaeth Automobile Company, Cleveland, Ohio, are making extensive improvements to their factory and office. They have put new cement floors in their factory, increased the number and size of the windows, and installed considerable new machinery. The office is being entirely remodelled and refitted.

We are informed that the Rambler payroll now contains nearly 1,200 names, or about 300 more than the previous maximum. It is asserted that this year's business of Thomas B. Jeffery & Co., will surely break all previous records, and most of the cars being turned out are of the higher-priced grades, the average selling price being \$2,000.

The Inst Lighter Company, recently organized by Columbus men to place on the market an apparatus for lighting auto lights without the driver leaving his seat, has established an office and factory on East Main street, Columbus, Ohio. The device consists of a valve and electric spark which ignites the gas. Fred C. Bargar is president and W. H. Gardner is general manager.

The New York Trade Association held a special meeting on Tuesday with Gen. John T. Cutting in the chair. A special committee of three was appointed to revise the bylaws of the association to enable it to take a more active part in the conduct of automobile events in and around New York in the future. It is said to be planned to double the annual dues.

J. M. Quinby & Co., of Newark, N. J., the well known carriage and auto body builders, have acquired a controlling interest in the Isotta Import Company, 1633 Broadway, New York city. P. Fremont Rockett is manager of the company in New York. The company plans to establish agencies in all the larger cities, which is rather a novel move for an importing firm.

#### Club Notes.

The Texas Motor Club, of Dallas, Tex., is planning to buy a building site and establish a clubhouse and grounds. A committee was appointed some time ago, and a meeting was called for the purpose of taking definite steps in the matter.

The Asheville (N. C.) Motor Club was organized at a meeting held at the Y. M. C. A. in that city on October 9. The following officers were elected: E. C. Sawyer, president; Dr. C. B. Reynolds, vice president, and D. L. Jackson, secretary and treasurer.

The A. C. of Maryland held its annual meeting and election of officers at the clubrooms on Mt. Royal avenue on October 12. The following officers were elected: Howard Milliken, president; Osborne I. Yellott, vice president; Thos. G. Young, treasurer, and F. W. Darling, secretary.

The Hartford (Conn.) A. C., at a meeting held on October 11, decided to reduce the quorum of the club from thirty to fifteen. The proposed club run to the Vanderbilt Cup race was abandoned, owing to apparent lack of interest among the members. Hiram Percy Maxim gave an illustrated talk on his gun silencer.

The St. Louis A. C. is planning a two day endurance run for the Hagerman trophy and one other prize. The contest for the Hagerman trophy, which has been run twice before, has never been decided, as in the first contest all sixteen contestants finished with perfect scores, and in the second two cars tied for the trophy.

The Milwaukee A. C., at its annual meeting, decided to proceed with the clubhouse project, and work will be started early next spring on a reinforced concrete building, in rustic style, on the club's tract of 3 acres on the Blue Mound road, a trunk highway to the west of Milwaukee. Another acre will be purchased, giving the club one of the prettiest and best club house sites in the country. Clarke S. Drake

was re-elected president. F. Austin Prinz was elected vice president; George A. West, second vice president; A. C. Brenckle was re-elected secretary, and Lee A. Dearholt treasurer.

The Motor League of Rhode Island has approached the American Automobile Association with the object of affiliating with that organization. This move is said to be the result of the difficulties encountered by the league in connection with the proposed race meet at Providence, R. I., recently, which had to be abandoned.

The Huntingdon Motor Club is being organized at Huntingdon, Pa. Two meetings have already been held and a third meeting has been set for October 26. Already twenty-eight automobile owners have joined the club. The temporary officers are as follows: Wm. Reed, president; Robert J. Mattern, treasurer, and Chas. Vuille, secretary.

The New Jersey Automobile and Motor Club, of Newark, N. J., held its annual run on October 10 to Newburgh, N. Y., and back, which was participated in by about 100 persons. The members of the club left Newark about 9 o'clock a. m. and reached Newburgh, a distance of 60 miles, shortly after 12 o'clock. The return trip to Newark was begun at 2:15.

The technical committee of the Chicago Motor Club are considering the holding of another demountable rim contest. The first trial of this kind ever held was conducted by the Chicago club about a year ago. If it should be decided to repeat the contest the rules would probably be materially changed, and in addition to demountable rims other devices designed to economize time lost through tire troubles on the road would be admitted, such as detachable rims and spare wheels.

#### New Incorporations.

Suburban Motor Transit Co., Elizabeth, N. J.—Capital stock, \$50,000.

Paige-Detroit Motor Car Co., Detroit, Mich.—Capital stock increased from \$5,000 to \$100,000.
Gramm-Logan Motor Car Co., Bowling Green, Ohio.—Capital increased from \$100,000 to \$200,000.

Slip-over Tire Co., Marion, Ind.—Capital stock, \$3,000. Incorporators, John W. Fudge, Fred Gephart and Geo. M. Kocher.

Burns Motor Car Co., Macon, Ga.—Capital stock, \$10,000. Incorporators, H. K. Burns, T. O. Parker and J. A. Smith.

The Rhodes Motor Co., Duluth, Minn.—Capital stock, \$50,000. Incorporators, A. L. Rhodes, Frank Crassweller, Elmer F. Blu.

The Detroit Roller Bearing Co., Detroit, Mich.

—Capital stock, \$50,000. Incorporators, J. M.

Hibbard, R. M. Brownson and A. B. Hibbard.

The Rambler Auto Co., Indianapolis, Ind.—Capital stock, \$10,000. Incorporators, F. G. Kamps, Jr.; W. H. Jordon and A. J. Gardner.
Royal Garage and Taxicab Co., Atlantic City,
N. J.—Capital stock, \$125,000. Incorporators,

N. J.—Capital stock, \$125,000. Incorporators, Wm. H. Conn, Paul D. Royal and Chas. F. Sesinger.

The Decatur Motor Car Co., Decatur, Ind.— Capital stock, \$150,000, Incorporators, J. S. Bowers, M. E. Brackett, C. C. Schafer, L. A. Graham, M. Kirsch and W. J. Vesey.

The Buick Auto Supply and Garage Co., Saginaw, Mich.—Capital stock, \$100,000. Incorporators, Judge Wm. Glover, Mayor Geo. W. Stewart, ex-City Treasurer Geo. S. Lockwood, David B. Buick, Thos. D. Buick, Geo. B. Brooks, Wm. F. Paine and Fred E. Button.

The Royal Automobile Co., Minneapolis, Minn. -Capital stock, \$50,000. Incorporators, I. A. Thorson and E. J. Johnson.

The Dycus Auto Co., Dallas, Tex.-Capital stock, \$3,000. Incorporators, D. Dycus, Henry T.

stock, \$3,000. Incorporation.
Leslie and Oliver Nichols.
Scott Governor Spring Co., Springfield, Ill.—
\$25,000. Incorporators, Geo. N. Capital stock, \$25,000. Incorpora Scott, F. Harding, A. Stubblefield.

The Dunham-Yager Motor Car Co., Louisville, Ky.—Capital stock, \$12,000. Incorporato Dunham, Roy T. Yager and A. M. Dick. Incorporators, Geo.

The Allen Lamp Co., Atlanta, Ga.—Capital stock, \$25,000. Incorporators, E. E. Allen, A. Calhoun and oJhn T Dennis (automobile lamps).

Rambler Automobile Co., Indianapolis, Ind. Capital stock, \$10,000. Incorporators, Frank G. Kampa, W. H. Jordan and Arthur J. Gardner.

Cialer & Serison, Chicago, Ill.—Capital stock, 6,000. Incorporators, J. Serison, Edward Cialer and Chaa, Kramerer. Automobile and supply

Great Southern Automobile Co., Birmingham, Ala.—Capital stock, \$100,000. Incorporators, E. F. Enslen, Ike Adler, John J. Kyser, E. F. Enslen, Jr.

Northern Auto Pressure Gauge Co., Los Angeles, Cal.—Capital stock, \$10,000. R. J. Northam, L. K. Northam, W. E. Sandham and P. W. Schenck.

Ideal Electric Co., Chicago, Ill.—Capital stock. \$1,500. Incorporators, J. A. Ryerson, S. H. Peterson and M. Mathison. To manufacture and deal in automobiles, accessories and supplies.

#### Trade Personals.

Frank E. Jarvis, traffic manager for the C. I. Shoop Medicine Co., of Racine, Wis., for several years, has been selected for the position of chief purchasing agent of the Mitchell Motor Car Co.

John D. Murphy, until recently automobile editor of the Boston Herald, has become associated with the Frank Presbrey Co., New York, and will handle the automobile publicity placed with that company.

Edward F. Korbel has been appointed press agent of the Tenth National Automobile Show, to be held in Madison Square Garden, New York, as successor to Arthur Jervis, whose chief assistant he was at the former shows.

Raymond S. Joo, formerly connected with the B. F. Goodrich Co., of New York, is now New England manager of the Rainier Motor Car Co., with headquarters at Boston. He succeeded Geo. T. Gould, who established the Boston Rainier branch.

W. H. Yule, of Kenosha, Wis., has been appointed manager of the New York branch of the B. F. Goodrich Co. Mr. Yule has been connected with the Goodrich Co. for some time, having held a position in the golf ball department at the factory in Akron, Ohio.

H. A. Capron, manager of the Rhode Island Motor Car Co., of Providence, R. I., died on October 11 at Pawtuxet Neck, of a complication of diseases. Mr. Capron was a member of the Rhode Island Automobile Club and the American Automobile Association. He was fifty years of age, and leaves a widow and three children.

Ezra B. Kirk has been appointed Western sales manager for the Rainier Motor Co., of Saginaw, Mich. Mr. Kirk is well known in the industry as a former automobile manufacturer. He was part owner of the Kirk Bicycle Co. which produced the Yale car, and later became sales manager for the E. R. Thomas Detroit Co., and then factory manager for the Rainier Motor Co. Recently he has been Western manager of the Herreshoff Motor Co., of Detroit, which position he relinquished to resume his connection with the Rainier Co.

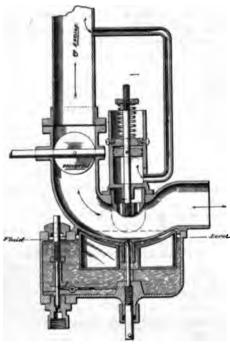

According to official figures there are at present 3,311 automobiles and 1,770 motorcycles owned in Vienna, Austria.

#### MOTOR VEHICLE PATENTS

#### Review of Specifications.

Carburetor.—Alexander Win-028 82R ton, of Cleveland, Ohio. July 20, 1909.

This invention relates to that type of carburetor in which the slowly moving volumes of air are subjected to surface car-

No. 928,828.

burization, and the rapidly moving volumes of air to spray carburization. This is also known as the puddle type of carburetor. The present patent relates to detail improvements on a carburetor which is the subject of another application for a patent filed jointly by Mr. Winton and Harold B. Anderson. It relates particularly to a method for keeping the richness of the charge formed constant independent of the position of the throttle valve. Referring to the figure, it will be seen that the carburetor comprises a downwardly curved, substantially horizontal pipe section. the lowest point of this pipe section there is a small opening through which it communicates with the float chamber of the carburetor, and the float is so adjusted that there is a slight amount of gasoline standing at the bottom of this pipe section, forming a puddle. The air passing through this pipe section will be charged more or less with gasoline vapor, according to its velocity, and in order to obviate this variation a sort of gate valve is provided which obstructs the passage through the pipe section directly over the spray opening more or less. The stem of this gate valve has secured to it a piston adapted to move up and down in a small cylinder, the lower end of which communicates through a tube

with the inlet pipe to the engine, above the throttle. That portion of the stem of the gate valve passing beyond the cylinder is surrounded by a coiled spring which bears against an adjustable nut.

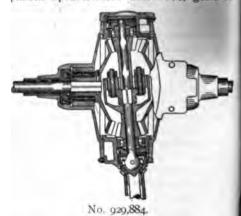

When the throttle is fully open the vacuum in the inlet pipe is very slight, and the spring surrounding the stem of the gate valve then draws the valve to its highest position. If, however, the throttle is partly closed, the vacuum in the inlet pipe above the throttle will be stronger. This vacuum will be communicated to the small cylinder above referred to, and the suction on the piston thus resulting will draw the valve down and restrict the opening through the pipe section directly above the spray nozzle. The velocity of the air past the spray nozzle is then less, but as the air comes into more intimate contact with the gasoline it is charged with gasoline vapor in substantially the same proportion. 929,884. Differential Gearing and Re-

versing Mechanism Therefor.—David E.

Ross, of Lafayette, Ind. August 3, 1909.

Filed April 13, 1906.

According to this construction the differential gear is placed on an extension of the propeller shaft, and the power is transmitted through bevel gears only after having been transmitted through the differential. Referring to accompanying illustration, the propeller shaft at its rear end connects through a universal joint, with an extension on which is carried a disc carrying two planetary sinions. These pinions mesh with a central pinion and an outside internal gear respectively, the two connecting through hollow shafts with two bevel pinions. Each of these bevel pinions meshes with a bevel gear connected to one of the rear axle drive shafts. The central shaft of the differential gear is not at right angles to the rear axle shafts, but is slightly inclined, so that the two concentric bevel pinions upon it mesh with bevel gears of

opposite sides. The central shaft of the differential gear is securely held in postion by eccentric bushings in the casing By revolving these eccentric bushings through a half revolution, each of the bevel pinions may be brought into mesh with the other bevel gear from that with which it meshed first, whereby the motion of the car is reversed.

**NUMBER 17** 

#### Autogenous Welding as Applied to Automobile Parts.

BY HENRY CAVE.

At this season of the year when many automobilists can look back upon disappointments, due to sudden breakages of important parts of their cars, which have prevented their arrangements being carried out, or are contemplating having cracks of more or less importance permanently repaired during the approaching winter months, it is advisable for them to investigate the possibilities of autogenous welding by means of the oxyacetylene flame as a means of quickly repairing these breaks and thus doing away with the long delays attending obtaining replacements, and also considerably reducing the cost of carrying out this work.

It is also possible that the machine is an imported one, and spare parts are not to be had in this country. In that case the saving is, of course, much greater; or the car may be of such an early make that parts cannot be obtained any longer, or the damage may be so extensive as to

Fig. 1.

make it inadvisable to have new parts made. It may also be required to make a change of design, such as remodeling a touring car into a truck or lengthening the wheel base, in which event sections can be welded into the frame to produce the desired change.

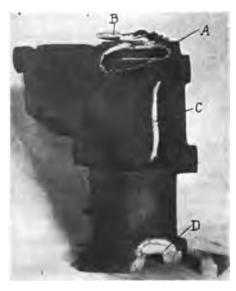

The use of the oxy-acetylene torch is well shown in Fig. 1, in which a break in a pressed steel automobile frame is shown welded, the work being carried out without even removing the body. The extent to which the paint was scorched can readily be seen. Metal is built over the break on the outside to insure ample strength, and is not noticeable when painted. If necessary, however, this reinforcement can be added on the inside. The outside is then filed off,

and there is then no sign of the frame having been broken.

The use of this process must not be considered in connection with automobiling alone, as it is equally applicable to repairs of all metals. Nor must its use be considered only as a means of repair, as there is a very large field of usefulness in connection with manufacturing, not only as a means of correcting errors in workmanship and defects of materials but also in uniting parts that have heretofore been riveted or bolted.

The process also opens up tremendous possibilities in connection with pressed steel, as parts can be pressed separately and welded together that would otherwise have to be made from castings. The extent to which this can be carried out is shown in Fig. 2. The parts of this exhaust manifold are made from steel tubing, the branches and flanges being all welded on, as well as the boss on the side. The end of the main tube is also closed by a disc of sheet metal welded in place.

The cylinder shown in Fig. 3 well illustrates the three main breakages to which these castings are subject. one illustrated, however, has been prepared as a sample. At A a break is represented that would result from the head of the valve breaking off and being forced against the crown of the cylinder and cracking it. The pieces B were cut out of the water jacket so as to weld the break from the outside. These pieces are then replaced and welded in. C represents a crack in the water jacket such as results from freezing, and D shows the tearing away of one corner of the bottom flange. This is welded entirely from the outside. metal being added to fill the corner so as to insure ample strength. The weld is not carried completely through to the bore, as that would necessitate remachining, which is not necessary otherwise. The line of the break which is left does

F1G. 3.

no harm and simply helps to spread the oil. It is, of course, possible to entirely obliterate all signs of the break if desired, but this is seldom done.

The fact that some of the broken parts are missing would not prevent this method of repair from being carried out successfully, as metal can be built in, or if of too extensive a nature for this a new part would be cast and welded in. In the same way a change of design could be obtained by removing a section and welding a new piece in of the desired shape.

The extent to which these changes in design can be carried out is well illustrated by the aluminum crank case shown in Fig. 4, it being desired to convert a four cylinder automobile engine of a well known type into a six cylinder. A damaged crank case was obtained and the two cases were then divided up so as to give the desired results, and were then welded together as shown. The repairs that had to be carried out can also be seen.

If it had been necessary to make an entirely new easting the cost of the job

FIG. 2.

Fig. 4.

would have been prohibitive, as the pattern would have been a very expensive item, and the case would have required machining by hand, as it would not fit into the jig ordinarily used. The original crank case utilized would also have been of little value.

This work, as well as that represented in the other illustrations, was carried out by the Autogenous Welding and Equipment Company, Springfield, Mass.

A good idea of the extent to which aluminum cases can be repaired is given by Figs. 5 and 6. Even more extensive damage than this could be satisfactorily repaired.

Fig. 7 illustrates a case in which a considerable saving was effected by the use of the autogenous welding process. The only defect was the splitting of the threaded steering knuckle pinhole by a too tight screw. This was welded up from the outside without injuring the

thread, and sufficient metal was built over to insure ample strength. The charge for this work was a very small percentage of the cost of a new axle, and there was no other possible way of satisfactorily repairing it.

A careful consideration of the above representative repairs by means of the oxy-acetylene torch will enable the reader to judge whether it be possible to repair breakages of any particular part of an automobile by this means, and to decide whether a new part is necessary or not

#### Book Reviews.

Automobile Troubles and How to Remedy Them. By Charles P. Root. Published by the Charles C. Thompson Company (not inc.), 338-344 Wabash avenue, Chicago. Price, \$1.50.

In this book the various troubles that occur with automobiles are taken up in alpha-

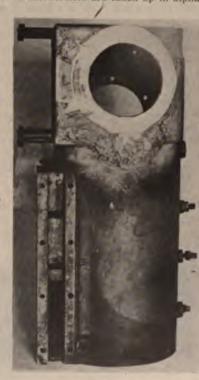

Fig. 5.

Fig. 6.

betical order, their symptoms are enumerated, and the remedies described. In the first part of the book there are two tables, headed, respectively, "Symptoms" and "Causes and Failures—Their Symptoms and Causes." The different troubles that occur on gasoline cars are then taken up and discussed in detail. The book is well written and should prove helpful to those who have to locate and remedy automobile troubles. It is illustrated, but only very sparingly. The volume contains 220 pages and is bound with flexible leather covers.

Luftfahrzengbau. Konstruktion von Luftschiffen und Flugmaschinen (Air Vehicle Construction. Design of Airships and Flying Machines). By Dr. Fritz Huth. Published by M. Kragn, Berlin, W., Germany. Price, 7.50 marks in paper covers, 8,70 marks in boards.

This book undoubtedly comes at an opportune time, covering a subject in which widespread interest is just being awakened

Fig. 7.

by the almost daily reports of new achievements in aerial navigation and flying. Dr. Huth's work is of a scientific and technical character, as distinguished from popular works. Only little space is given to the history of the subject, and the greater part of the work is devoted to minute descriptions of the leading types of airships and flying machines, and to a discussion of the underlying principles. In fact, as the title would lead one to expect, the book is written for the benefit of the experimenter and builder and not so much for those who take a sportsman's interest in aerial locomotion The book is profusely illustrated, both with half tones and line cuts, and it incorporates a considerable number of plates, for the most part of airship and flying machine motors

At a meeting of leaders in the German motor movement, including Prince Henry, at Berlin, on October 4, it was decided to hold the contest for the Prince Henry Cup again next year within the boundaries of the German Empire, June 1 to 8. The handicap of professional drivers will be abandoned. Two speed tests will occur in the itinerary—the first between Genthin and Burg, and the second on the old Kaiser Cup course between Limburg and Weilburg in the Taunus.

#### Design of a Motor Propelled Ambulance.

BY JOSEPH LEDWINKA.

Plate I is a suggestion in motor ambulance design. This design of body is applicable to any chassis with gasoline or electric propulsion. The tread of the wheels, or better, the over-all dimensions over the tires, should be preferably made to fit the street car tracks of the particular town in which the vehicle is to be operated. In that case the use of the smooth rails, especially in badly paved streets, will give more comfort to the patient and will also make higher speed possible.

The body construction with stretcher arrangement, as shown in the design, is largely used in European cities. It has been proven that this is the most convenient and most cautious way of conveying a patient into the interior of the vehicle body. The interior is wide enough to allow two or three attendants or physicians to work there in cases where the injured person needs immediate treatment. The most necessary appliances are provided, and are easy of access.

The body is built like delivery wagon bodies. The right hand side of the body proper is hinged along the lower edge above the wheel panel and drops to a horizontal position over the rear wheel and mud guard, exposing the whole length of the specially constructed stretcher. This stretcher is provided with rubber tired wheels which run in grooved rails built into the inside of the hinged side door. The rails, which continue to the interior, are hinged to the one on the door and permit of the free opening and closing of the door. They form a continuous groove for the wheels to run in. The inner ends of the grooved rails are curved upwardly, acting as a stop for the wheels, and are supported on pivotal legs to maintain a horizontal position. On the opposite side in the interior are three or four singly hinged seats which fold upward out of the way.

Above the large side door are window sashes provided with frosted glass panes, and made to open inwardly about three inches, with the hinges on the bottom. The front partition, separating the interior from the driver's seat, has a small drop window, about 12x18 inches. The door at the left rear end of the body is hinged to the left corner post and has a drop window

down to the surface. The whole interior, except the sheet iron lined roof, should be covered with 3-32 inch thick plain rubber sheeting which must be cemented to the wood. The sheet iron ceiling should be painted to resemble the color of the rubber on the sides.

In this way a very neat as well as sanitary interior is obtained which can be cleaned and disinfected by means of a hose. All the chests holding medicines and instruments are removable. On the roof

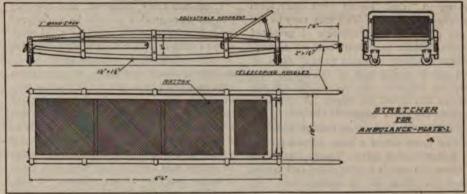

FIG. 2.

and roller curtains. The other window at the rear end is of frosted glass, as are the narrow ventilators underneath the roof at the rear end.

In building an ambulance the aim should be to avoid all sharp corners and crevices in the interior which would permit of the accumulation of dust and germs. This requirement is generally overlooked, which makes the disinfection and cleaning a hard or impossible task.

The inside of the roof should have a sheet iron lining, binding the bows; the sheet iron should come down all around 1½ inches in a curve of one inch radius, forming a round corner. The four sides should all be paneled to form a smooth even surface; all corners should be provided with concave moldings, smoothed

are three galvanized tanks containing cold water, coal oil and hot water respectively. The coal oil is led through pipes to a burner underneath the hood of the driver's seat for heating the water in the tank on the roof. The hot and cold water are led into the interior for the use of the attendants. A small basin to receive the water is hinged to the front partition and empties itself when turned up. Electric lights overhead and extension cords with hand lamps fed from a small storage battery furnish illumination.

The stretcher, with the main dimensions shown in separate cut, is made entirely of white ash or hickory. The sides are bent without special preparation of the wood. The curves are slight and can be bent easily.

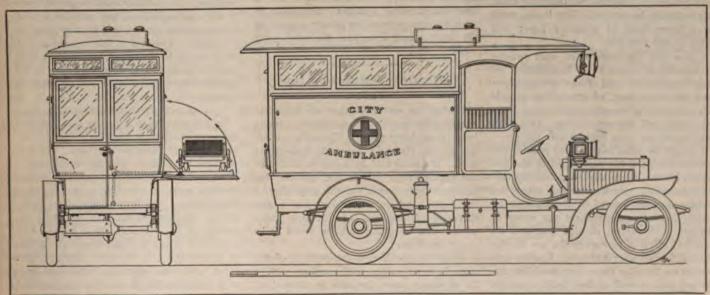

Fig. I.

## Home Made Fire Extinguishers for the Car.

I note J. M. Prudden's article, "A Home Made Automobile Fire Extinguisher," in The Horseless Age of September 22. Another way to make a dry powder extinguisher is to saw in two a small tin can having an "Ideal" top or some other form of "pry open" cover. This may vary in size from a can such as samples of prepared foods come in to a syrup can of a much greater diameter. Take a piece of sheet tin and roll it into a tube of the proper size. Use the halves of the can as the top and bottom and solder the edges. A ring fastened to the cover completes the job.

I believe that in every roll of Ruberoid roofing there comes a long, tubular tin can of Ruberine roof paint. Except that it has a screw top and is a little short this is just about the thing for an extinguisher. By fitting the top with some sort of a ring or key handle to make unscrewing quick and easy, and giving it a coat of paint for looks. it should make a pretty good auto extinguisher.

On an automobile weight is usually to be considered, which might make an extinguisher made out of lead pipe rather objectionable. A very light, inexpensive and easy way to make an extinguisher is to take a large pasteboard mailing tube, such as is used to hold pictures, drawings, etc., and fit a wooden plug tightly into one end. Secure it there by putting tacks through the sides of the tube. Stop the other end with some kind of a cork or plug. Put a large screw eye through the cork to hang it up by.

Put a metal washer on the inside of the cork and bend the end of the serew over at right angles to prevent its pulling out. By dipping the cork in melted paraffin the necessary amount of friction and tightness of fit can probably be secured. For looks, paste on a large sheet of wrapping paper and paint to suit yourself.

I note that the contents of most powder extinguishers consists of bicarbonate of soda (saleratus) and from one-half per cent. to 10 per cent. of starch, red or yellow ochre, fuller's earth or some other powder which will prevent caking. This does not deteriorate from contact with the air.

It might be remarked that dry powder fire extinguishers are not recognized by the fire underwriters. Generally these extinguishers generate a smothering gas when the powder becomes heated by the flames. In liquid chemical extinguishers the water is charged with carbon dioxide gas, and its principal office is to convey the gas to the fire and thus smother it at once. The fire underwriters consider these very good, but the item of cost, as well as their bulk, seems to prevent their use on automobiles. Yet a

quart extinguisher of this type can be bought for about 25 cents! For what else is a siphon bottle of aerated water, such as vichy? To be sure, it is made of glass, but the walls of the bottles are quite heavy and much more delicate articles are often carried on automobiles. One defect, however, might be the temptation to have a drink on hot days and thus run the risk of having the bottle empty when a fire occurs.

I should think, also, that a tire tank carrying carbonic acid gas would be useful as a fire extinguisher.

I do not think, however, that the dry powder extinguisher should be considered entirely without merit. At least, bicarbonate of soda is lighter than sand. The value of this extinguisher was demonstrated to me but a short time ago. A glass kerosene lamp had been left burning on a window seat. The window was open, but the shade was pulled down. A stiff breeze was blowing, which pushed against the shade so strongly that the lamp was tipped over and thrown down under a low tub whose rounded bottom was supported by four legs, about 6 inches long, set at the corners. It happened to land just inside one of the short legs. The kerosene caught fire. To have thrown water over it would have been to spread the flames all over the floor, and the tub leg and lack of space between the tub bottom and the floor prevented the use of several small rugs which happened to be handy. Finally, a powder extinguisher was brought, and a few flirts of that put the fire out completely. I should think a fire of this nature might easily happen around an automobile or in a garage. On investigating it was found that the porous powder had absorbed the oil, forming a kind of mud. Over this was a layer of dry powder which had shut off all air, thus stopping combustion. Such a fire might have been put out with a siphon bottle, but it would have been much harder to clean up. As it was, it was merely necessary to sweep up the broken glass and powder, and throw it into an ash can. It would seem a pity to have discharged a 3 gallon extinguisher on such an unimportant fire where a quart of the liquid would have done the work.-Jay Teel.

## Vulcanizing Patches on Inner Tubes.

During the warm weather we have had considerable trouble from patches coming loose from inner tubes. Naturally we began to cast about for a way to make them stick. We were told by a representative of the manufacturer whose tire we use that acid cure only "cures" at the very edge of the patch, and so we looked for a still more secure method of patching inner tubes. The following solution seems to be a very good one:

Clean the patch and the portion of the tube it is to cover and roughen with a file of emery paper, the same as when about to apply an ordinary patch. Coat the above

mentioned surfaces with a cement made by dissolving raw rubber in gasoline, and when it is sufficiently dried apply the patch. Have a clamp made by drilling two holes through the ends of two small metal plates similar to an "inner tube repair clamp." One of the plates must be thick enough so that a hole may be drilled in it to hold a thermometer. Clamp the portion of the tube having the patch firmly between the two plates and protect the adjacent parts of the tube with cardboard, or, if necessary, with asbestos paper. All parts of the tube except the patch itself should be kept out of contact with the metal. Of course the patch and all the rubber which comes into contact with the paper should be thoroughly dusted with talc powder before applying the clamp. Suspend the clamp in the air or prop against some bricks and heat to 135° C. for twentyfive minutes. The thermometer to be used is similar to a medical thermometer, but registering up to at least 200° C. The heat may be applied by means of alcohol or gasoline blow torches, a Bunsen burner, alcohol or kerosene lamps. I have found the alcohol blow torch to be the most convenient for my use. Play the torch against the plate touching the patch, which should also hold the thermometer. Reduce the flame gradually as the temperature rises. To use a lamp or Bunsen burner the clamp must be suspended almost horizontally, taking precautions, of course, that the thermometer does not fall out. If lamps are to be used bring the temperature up with an alcohol lamp and hold it there with a kerosene lamp.—Jay Teel.

#### Some Repair Shop Notes.

SMALL SENSITIVE DRILL.

A novel drill for drilling small holes, as for cotter pins, etc., is in use at one of the repair shops in New York city. It is made very light so as to avoid frequent breaking of the drills. The power is furnished by a small compressed air turbine which will run up to 12,000 r. p. m. on 100 pounds air pressure. The turbine shaft is geared down to the drill spindle in the ratio of 4 to 1. Lower speeds are obtained by throttling the air supply. The drill is said to have proven most satisfactory in operation, and to have saved a great deal of expense, owing to the fact that ordinary drills are broken very frequently.

AIR-OPERATED GREASE GUN.

In the same shop a grease gun operated by compressed air is used for filling the differential gear cases with grease. The gun consists of a brass cylinder containing a plunger below which the grease is compressed, with air connections at the top of the cylinder. The lower head of the cylinder is clamped on and can be easily removed; it has connected to it a hose with a suitable nozzle through which the grease is forced out. It is stated that the gun saves much time when the differential cases of a large number of cars have to be filled, and is a convenience at all times.

#### The Plight of the Carriage Industry.

If there was still a vestige of doubt left in the mind of anyone regarding the condition of stagnation in the carriage industry. and particularly that branch of it which specializes in stylish and luxurious rigs for the wealthy, it was dispelled by the admissions of President Connolly, of the Carriage Builders' National Association, at their annual meeting in Washington, D. C., last week. The automobile, Mr. Connolly asserts, is monopolizing the attention of those who can afford to buy the good things in the carriage makers' line, and he claims to have observed, moreover, that people have become more liberal with their money since the automobile arrived on the scene. He states that those who a few years ago would make a sacrifice to save \$100 or \$200 in a carriage will now pay \$6,000 for an automobile, although most of them are not now in as good circumstances as they were then.

Mr. Connolly believes that the salvation of the coach builders lies in entering the automobile industry themselves. That many other carriage builders are of the same opinion has been evident for some time, but whether this step will really prove their salvation remains to be seen. The carriage builders certainly made a big mistake when they allowed the manufacture of automobile bodies to slip out of their hands. All the early bodies for automobiles were built in carriage shops, and the work on the bodies today is done by the same class of men-body makers, carriage blacksmiths, carriage painters, etc.-as are employed in carriage shops, only they are employed in the body department of automobile factories or in special automobile body establishments. The construction of automobile bodies would have naturally fallen within the province of the carriage builder, and few automobile manufacturers would have thought of establishing their own body departments if they could have secured bodies of suitable design and been assured of satisfactory work and prompt deliveries. But it seems that most of the carriage builders looked with disdain on the automobile, regarding it as a passing fad, and considered themselves superior to taking instructions from the auto makers regarding points in construction which were not in accordance with their own experience.

In a carriage the body is generally the most important part, from the standpoint of cost of manufacture, but in the automobile the chassis is considerably more important. The average carriage builder does not make his wheels, axles, springs, etc. He buys these parts and assembles them, and then applies a body of his own manufacture and sells the complete vehicle. It is now possible to proceed in the same way in the manufacture of automobiles. That is, all the component parts of a chassis can be bought in the market and the carriage builder can assemble them, fit his body and market the car. Unfortunately for him the selection of the parts and the assembling thereof are tasks for which he is not equipped by experience, and upon the selection of well made parts, all properly proportioned for the weight and power of the car, and upon their careful and workmanlike assembling depends the success of the machine,

The carriage builder naturally desires to become an automobile manufacturer, to enable him to maintain his relations with his agents; but in our opinion his proper place in the auto industry is that of a parts maker, furnishing bodies to the automobile manufacturers, as the assembling of automobile machinery is rather too much out of his line. To take up the assembling of the chassis he must install special equipment and engage a special staff, experienced in this line of work. It would undoubtedly be much easier for him to secure a goodly share of the auto body business than to enter into successful competition with experienced automobile assemblers.

#### A Possible Readjustment of Auto Prices.

It would not be surprising if there should be a slight general increase in automobile prices during the coming winter. There have been various indications of late of such a tendency, and the conditions are certainly ripe for such a move on the part of the makers.

In the first place, it should be remembered that during the depression in the industry following the financial panic automobile prices tumbled, and in their endeavor to secure as large a share of the available market as possible some of the manufacturers went rather close to the dividing line between profit and loss. Whether it was this lowering of prices or the recovery of the public from the effects of the panic that did it, at any rate the demand for cars grew enormously during the past year. With the increase in the rate of production to meet the increased demand there came, however, a scarcity of raw material and of skilled labor, and increasing competition for the available supply of both led to an increase of their prices.

The most important instance of an increase in the price of raw material used in automobile manufacture is furnished by crude rubber. This commodity now sells at twice the price at which it could be bought two years ago. The auto manufacturer, of course, does not buy crude rubber, but rubber tires, and the price lists for these have been "upwardly revised" twice within a few months. The tendency in other materials purchased by the auto makers is also upwardly, notably in leather and curled hair for upholstering. Steel prices are also rising, owing, it is said, to increasing activity in all lines of industry, and though the total cost of the steel in a car is a small item when compared with the selling price, yet an increase in this item of 10 or 15 per cent. counts if the margin of profit is already quite narrow.

The cost of skilled labor is also rising, especially in the Middle West, where there has been an unprecedented demand for machinists and other metal workers experienced in automobile work of late. We know of several instances where large automobile manufacturers in that part of the country sent representatives to the various large cities to search the labor markets there for skilled mechanics

There has also been some talk of an inclination among parts makers to raise their prices, and combinations in particular lines of manufacture have even been hinted at, though these rumors are probably without foundation. If the parts makers actually should insist on higher prices it would not be at all surprising in view of the above remarks regarding conditions in the labor and raw material markets, which affect the parts manufacturer as well as the car manufacturer.

So far three of the most prominent models of the past season have been increased in price. Although a more complete equipment in each case accounts for part of the increase, we believe that the manufacturers in raising their prices were mainly actuated by the increasing cost of production.

#### Trend in Front Axle Design.

For years past the I beam type of front axle has been rapidly supplanting other types. At the present time the manufacturers still adhering to tubular axles are very few, although one or two of them are of distinguished reputation.

The delay which has been noted in making this change has probably been due more to commercial reasons than to a failure upon the part of automobile engineers to recognize the desirability of the step. Most mechanically trained men of the industry have long ago recognized the superior fitness of the solid I beam section forging for this purpose, and also the importance of doing away with pinning and brazing in such a vitally important motor car element as the axle. It is only rather recently, however, that the metallurgical industry has been in condition properly to supply the demands made upon it in this direction. Considerable time was demanded for the development of facilities adequate to the production of axle forgings in the variety required to meet the varied demands of the industry in quantities and at satisfactory prices. The metallurgical industry and the parts makers are largely responsible for the creation of the facilities that are leading to the nearly universal use of I beam axles.

The development of means for producing an axle and steering yokes as a single forging without welds, the determination of the steels best adapted to the purpose and the most appropriate methods of heat treatment are among the lines along which progress has been made, under the insistent demand of the automobile engineer.

It is to be noted that a number of makers who have been using tubular front axles are announcing single piece, alloy steel axles of the I beam type, with integral steering forks and spring seats, as features of their 1910 product, and it is also worthy of remark that, almost without exception, the new models of low priced cars, which would a few years ago have been fitted with tubular axles, are now equipped with the I beam tvpe.

Of the I beam axle cast in special bronze, which was somewhat used a year or two ago, much less is now heard, but the pressed steel axle of channel section is assuming a somewhat greater prominence, in keeping with the general increase of popularity which pressed steel is now enjoying as an automobile material.

It may confidently be asserted that the present movement in front axle practice is in the direction of increased safety for the user and a lightening of car weight in proportion to strength. In cases of production upon the large scale it may also be in the line of economy in production.

#### Selling Commercial Cars in the Dead Season.

Every dealer will have observed that the interest of likely purchasers of pleasure vehicles rises and falls with the seasons. The first signs of spring awaken in every lover of nature and outdoor life the desire to own a vehicle enabling him to spend most of his leisure on the road, and persons who have ordered cars then often literally besiege the agencies, urging them to hurry delivery of their cars as much as possible, while those who have been deferring the placing of their order are induced by "the spring breezes" to take the step. All through the summer there are prospects for the immediate use of cars purchased, if they are delivered within a reasonable period, and this prospect necessarily helps along sales. Late in the fall, however, and during the early winter, people do not feel the need of touring cars so much, and sales of such vehicles naturally drop off considerably. The dealer in the larger cities then has the closed town car to fall back upon, and the prevalence of landaulets, broughams and limousines in

the traffic of our big cities shows that it offers quite an extensive field. But in the smaller cities and country towns it will probably always be impossible to place many of this class of cars, and the dealers in these localities have to look for other types for rounding out the selling season.

The one class of vehicle that can be sold equally well at any time of the year is the commercial vehicle—the truck or delivery wagon. In some respects it should be easier to sell a commercial vehicle in midwinter, because, as has been shown by experience, the motor vehicle is far more independent of extreme weather conditions than the horse. In New York city there have been many instances in recent years when during sleet storms or rapid thaws the streets were rendered so slippery that all horse traffic was practically at a standstill, while motor delivery wagons equipped with non-skids were spinning along with their usual celerity.

The dealer who suffers from lack of interest in touring vehicles at this time of the year will therefore be well advised to look into the prospects for commercial vehicles in his neighborhood, and if they are encouraging to take on a line of motor delivery wagons. A few good vehicles of this type placed now will, if they prove satisfactory to their buyers, tend to help along sales in that district later when the dealer may have even more important reasons for taking up commercial vehicles.

#### Material Specifications.

BY E. J. BARTLETT.

Purchasing agents or buyers of automobile supplies must be rather modest and retiring in disposition since one sees so little of their problems expressed in the columns of the trade papers. Yet the position is an important one and it would seem as though a more extensive interchange of ideas and methods pertaining to the purchasing of materials would be helpful, not only to the buyers but to their associates as well.

Possibly the closest associate to the buyer should be the engineer, since he, either directly or indirectly, specifies and is responsible for the constructional material purchased. Whatever the local factory conditions may be, there must necessarily be specifications more or less complete of the supplies required, and in a general way there are at least three sources from which these specifications come. These in the order of the importance of the material are the Engineering, Factory and Business Departments. In different factories departmental lines are drawn differently, but the results are substantially the same.

While specifications from the two latter departments are important, as they cover all supplies necessary for conducting the business, their volume and character for the most part do not make them as important as those issued by the former department, which covers the materials entering into the construction of the product. It is, therefore, highly important that the engineer work in close touch with the buyer and have as complete knowledge of the material market as possible, and not interfere with the direct duties of his position.

There are many simple ways in which the engineer can assist the buyer and save money for his company by using good sense and care in the material specified and the form in which it can best be used. In a way some of this work seems outside the province of the engineer, but since the buyer can hardly be expected to know as thoroughly the material and conditions under which it is used as the engineer, the latter is the proper person to decide many points which at first might seem more properly to belong elsewhere. Some simple precautions which may well be used in specifying material follow.

#### PATTERNS.

In small factories, in particular, much or all of the pattern work is placed outside, and one of the annoying difficulties of manufacture is to get correct castings from patterns made by the ordinary job pattern maker. The responsibility is divided. The pattern maker lays the blame on the molder, and the foundry boss says the pattern should have been made some other way. Between the two the factory stands for the delay and incidental expense and

finally pays the foundry for fixing up the pattern to suit its own ideas. In the long run it is usually cheaper and more satisfactory to put the pattern making up to the foundry and order castings which will machine to the print submitted. Most foundries of any size have a pattern department, and those which do not usually have some connection with a job pattern shop where they have their work done. In this way the foundry objections and excuses, so far as the patterns are concerned, are eliminated.

Even with such an arrangement the matter of stock for finish is often a disputed point. Some factories prefer more stock for finish than others, and again the shape of the finished surface and manner of handling the piece in machining has something to do with the amount of stock required. Some factories make separate drawings for patterns, which add to the expense and complication of the drawings. Others indicate by dotted lines on the shop drawings the amount of finish required, but this method often complicates the drawing, and no drawing can be too clear for the ordinary machinist.

The writer has found it good practice, for outside pattern making, to use the dotted line system as last mentioned, but mark duplicate prints only, one print being sent to the pattern maker and the other put on file. With well made drawings thus carefully marked up there is not much excuse for the foundry producing other than reasonably correct castings.

Where a considerable quantity of castings are to be made from a new pattern it is always a good plan to have a sample casting submitted to be laid out carefully by the factory inspector. This casting will be found handy in designing the tools and fixtures and can be tried in them when completed. With malleable iron too much time may be consumed in waiting for an annealed casting, and a hard iron sample will often answer the purpose. It should be noted, however, that a hard iron casting expands a little during the annealing process and allowance should be made accordingly.

Of course, the kind of pattern required should be specified, whether soft wood, hard wood, or metal, as well as the number on a gate, if gated. With some pieces very similar, but right and left hand, it is possible to have a part made loose and fitted in different positions on the same main pattern. This is particularly true of master patterns from which metal patterns are made.

#### DROP DIES.

The same precautions in regard to finish allowance apply to drop dies as to patterns, and lead casts should be used for testing the correctness of the sizes and for tool and fixture making. Where break-down dies are required it is sometimes well to specify whether cast iron or steel is re-

quired, depending on the probable amount of service required. Such precautions may save delay when the parts are badly needed.

BAR STOCK.

Since it is impossible to tell a year in advance the exact sizes and quantity of a grade of steel, it is customary to insure prices and deliveries by contracts for a certain length of time, usually a year, for a specified tonnage at a specified base price. This base price should be clearly noted in the contract as covering all diameters of bar stock of this grade within certain limits. All additions to the base price should also be given; these additions covering the extra price charged for delivering bars of such lengths as are multiples of any specified figure, annealing, heat treating, and sizes different than those covered by the base price.

With the conditions of the steel contracts in mind it is sometimes possible to specify the bar steel required more intelligently than would otherwise be possible. For instance, shafts of fairly good length for automobile work, such as the axle driving shafts, are usually purchased by specifying bars of steel of correct multiple length. To illustrate, we will suppose these shafts to be 321/2 inches long, 11/4 inches in diameter and made of 31/2 per cent. nickel steel. The base price of such steel for this diameter is about 6 cents per pound, and the addition for bars of multiple length is I cent per pound. This stock weighs 0.35 pound per inch, and with bars of random length the wastage may evidently vary from nothing to, say, 32 inches, or an average of 16 inches per bar. Random bars usually come of such length that at least five shafts may be cut from each. In the case of bars of multiple length we may then say the cost per shaft, less allowance for cutting, which will be the same in either case, will be 321/2 × 0.35 ×0.27=0.80. In the case of bars of random length the cost per shaft will be

 $(32\frac{1}{2} \times 5 + 16) \text{ o.} 35 \times \text{ o.} 06 = 0.75.$ 

This comparison shows it is actually cheaper, aside from the possible value of the short ends, to specify random lengths when an additional price is asked for selecting bars of multiple length. It is possible to obtain bars at least a certain length and let the variation beyond this come what it will, which seems the cheaper when the multiple length bars are more per pound. At the same price some little saving is effected.

In much the same manner comparisons may be worked out showing whether it is advantageous to buy such stock annealed, heat treated or cut to length, the answer depending largely on the factory equipment for this work.

The chemical analysis required is another important specification for steels used for severe service. It is clearly impracticable to obtain an exact analysis, and if such is specified the chances are that less care will be taken to get as close as possible than if reasonable limits were given. Usually a ten point limit may be given for the carbon

1

and manganese elements and an upper limit for the sulphur and phosphorus.

A very good and easy analysis for carbon automobile shafting may be specified as follows: 0.40 to 0.50 carbon, aim at 0.45; 0.60 to 0.70 manganese, aim at .65; 0.05 or below sulphur; 0.05 or below phosphorus.

Another point to be considered is whether black, cold rolled or semi-smooth stock is required, all different in price. Sometimes at little, if any, increase in cost cold rolled bars a few thousandths under size may be purchased, to use inside a steel tube, for instance, and save a machining operation. A good way to make such specifications is to order it of such a size that a ring of the required diameter will telescope it. The reverse applies to ordering steel tubing for such parts as spacers. It may be specified to telescope a plug of the required size.

#### MISCELLANEOUS.

In specifying tubing or sheet stock the decimal equivalent should be given as well as the gauge, thus: No. 16 B. W. Q. (0.065 inch). This will avoid all possibility of confusion in the different gauges.

Iron pipe should be specified in regard to thickness as standard, extra heavy, or double extra heavy.

Grease and oil cups should have the thread mentioned as well as the size and make, as there are often different threads furnished. Also specify the finish required after the relative prices are learned. The rough brass finish, for instance, is considerably cheaper than the polished brass, and for many places just as good. Such specifications, for example, would be No. 00 Empress ratchet grease cup, one-eighth of

#### Testing a Car on a Hill Course.

By Albert L. Clough.

It is not at all easy to assure oneself absolutely whether a car is operating with its wonted power or not unless definite tests are undertaken to that end. The operator is quite likely to be deceived into a false conclusion if he relies upon cursory observations unsystematically made. In making systematic tests upon the condition of a car the same piece of road should always be used as the testing ground, in order that each test may be fairly compared with those which have preceded it. A street or road should be chosen which possesses as nearly as possible a uniform surface at all times, an asphalt or a well cared for macadamized street, bearing a light traffic, answering the purpose best. The street or road chosen should include a hill or grade steep enough to slow the car down to a reasonable speed, say 20 miles per hour, on the high gear, with the throttle wide open and the spark in its usual position with, say, two persons aboard. In the case of a very high powered car all tests may be made with the throttle not fully open but open to a certain notch of the segment, which may be marked or otherwise noted.

#### TESTING HILL CLIMBING ABILITY.

Upon receiving a new car, putting it into commission in the spring or after an over-

THE HORSELESS AGE

an inch pipe thread, rough brass; or No. 4D Winkley oiler, Ax32 V thread, nickel.

Spring lock washers are other common parts which are made in a variety of forms. To be sure of what is required the section and type as well as size should be given. Thus, 36x3x1/4 inch positive type would specify a washer for a 3/4 inch bolt which had a section 3/4 inch wide by 1/4 inch thick with an upturned chisel end.

Many other examples of a similar nature could be given, but the above will serve to indicate that more concise information in regard to the material supplies than is usually given is of practical value.

It is, of course, not possible for the engineer of a large factory to give very much of his personal attention to such detail, but it is possible for him to train his men to a knowledge of such seemingly small matters. If the constructional materials are requisitioned outside of his department from his drawings, full specifications on the drawings are especially important. In small factories such requisitions are frequently placed with the buyer direct from the engineering office. Even then the drawings should be complete to serve as a basis and record.

hauling, a test of its performance up this hill may be made, and at intervals thereafter other similar tests may be made, which, when compared with the preceding ones, will give a very fair idea as to changes in operative condition. The test run should be begun at a certain point A at a short distance below the grade, and at a certain other point B just at the foot of the grade the car throttle should have been so manipulated that the car speed is a certain number of miles per hour. At this point B the throttle should be opened wide in the case of a moderate powered car, or opened to the chosen notch of the quadrant in the case of a high powered machine, and from that point on the speedometer should be watched. At a certain later point on the hill C, which will be the steepest portion of the grade, the reading of the speedometer should be accurately noted, this reading being the one of most importance in the test. If a magneto is used the spark lever may well be left unchanged throughout the test at a point about as high as will secure proper operation of the engine at the lowest speed reached, and the particular notch used should be noted and used in all succeeding tests. If the battery system of ignition is used the spark may be lowered as the car slows down, note being made of the highest and lowest points used on the quadrant, and the point at which the change was made

The gasoline tank should be filled to about the same point on each test; the top and wind shield should either be up or down on all tests, and the passenger weight and the weight of supplies should always be the same. Before making the test the car should be driven so as to bring the cooling water to about the same temperature in each run.

#### RECORDS.

A record should be made including such data as the following: Course (giving street or road); date; weather (giving approximate temperature and wind); passengers (give weights); condition of circulating water; wind shield and top (whether up or down); condition of tanks (whether full or not); ignition (whether magneto or battery system); spark position (give notch number or numbers on quadrant and place of change of spark position, if any); speed at point A; speed at point B; throttle opening used from B to C; speed at point C; remarks (covering any changes made in car since last test and running qualities of the motor and car).

Two records of this kind of tests made at different dates, when the items of "speed at point C" are compared, will give a pretty good indication as to the maximum hill climbing capabilities of the car upon the two dates.

#### BRAKE TESTS.

A test may be made in a similar manner and on the same occasion, using second speed instead of third. This will act, in a way, as a check upon the high gear test as regards motor condition. At the same time that the hill climbing test is made the brakes may also be tested. The car may be driven up to point C on the course, and stopped and the emergency brake set just hard enough to prevent the car from moving backward. The number of the tooth upon the ratchet may be noted and entered upon the record. If there is any change in this particular between two tests the amount of emergency brake adjustment required will be known. The car may instead be driven down the hill and stopped at point C, the notch on the brake quadrant which has to be used to hold the car from forward motion being noted. The foot brake may also be tested as to its sufficiency to hold the car against either forward or backward motion at point C, although as this brake has no ratchet exact data are not obtainable.

#### ADJUSTING THE CARBURETOR.

A course of this kind, including a hill of this character, is very handy when one is trying to secure a carburetor adjustment best adapted to hill climbing, the speeds

noted at point C on different runs giving a very good indication of the merits of various settings of the needle valve and auxiliary air openings. It is also very useful in comparing the relative hill climbing capabilities of different cars. The writer uses a hill in his home town for the purpose of "sizing up" the hill climbing qualities of cars of various makes, and finds the results very interesting. The driver is always asked to attain a certain speed at point B and at that point to open the throttle wide. The speed at point C, as indicated by the speedometer, is noted, and may be compared with the corresponding speeds obtained from other cars upon the same course. Points A, B and C are, in this instance, streets intersecting the course.

#### COASTING TEST.

In addition to the periodical tests of hill climbing capability and brake efficiency recommended above it may be of interest to make a coasting test which will indicate whether there is any change in the frictional resistance of the car. To carry this out the car should be headed down the hill and when point C is reached so controlled that it is running at, say, 5 miles per hour by the speedometer. At this point the spark should be cut off and the car allowed to coast, with the engine acting as a brake. It will speed up somewhat in going down the grade, and will then slow down as the more level portion of the course is reached. The point at which the speed has dropped again, to, say, 5 miles per hour, should be noted and recorded for future comparison. A closed throttle should be used. Whether the high gear or intermediate gear should be used will depend upon the steepness of the hill and as to whether a safe speed will be exceeded with the high gear in use. It may be possible to make a test with each gear in use. The further the car coasts the less is the total frictional resistance, including that of the engine.

#### FREE ENGINE COASTING TEST.

If a coasting test exclusive of the engine is desired the car may be driven down the hill to some point as D, reasonably near the foot of the grade, and stopped. The brakes may then be released, the clutch disengaged and the gear neutralized, when the distance which the car coasts will serve as a fair criterion of the frictional losses due to the running gear and the part of the transmission system which is in use. Instead of neutralizing the gear any one of the gears may be left in mesh, so that the resistance due to gear and gear shaft bearing friction may also be included.

#### RECORDS OF COASTING TEST,

The record of a coasting test should include, in addition to the date, the course used, passengers carried, the weather and so forth, a definite identification of the starting point and of the stopping point; the speed at starting and stopping (entering o on the record if the car is at rest at either end of the test); whether clutch was en-

gaged or disengaged, and what gear, if any, was in mesh.

A coasting test may sometimes throw light upon the results of a hill climbing test, as any undue frictional resistance produces the same effect as does a lack of engine output upon the capability of a car to mount a hill at speed.

Records such as suggested above are very interesting if carefully made at proper intervals of time, and definitely inform the owner as to how his car is maintaining its powers. They are often the means of calling attention to defects in ignition, compression, carburation, lubrication and faulty adjustments of the brakes and other operative parts of the car.

#### A Permanent Magnetic Metal.

A patent on a permanent magnetic metal, assigned to Charles F. Splitdorf, was issued on October 12 to Samuel E. Gertler, of New York. The invention consists in the addition of a small proportion of aluminum to alloy steel of permanent magnetic qualicies. Either tungsten steel or manganese steel may be used, or a steel containing both tungsten and manganese. According to the inventor, a suitable alloy may be made by

melting together ingredients to give the following composition:

Tungsten, 5.25 per cent. Carbon, 0.65 per cent. Silicon, 0.15 per cent.

Manganese, 0.25 per cent. Chromium. 0.20 per cent.

Sulphur and phosphorus, 0.02 per cent. or less. Aluminum, 2.5 per cent.

Iron sufficient to make 100 per cent.

It is claimed that a steel produced in accordance with the invention possesses high permanent magnetic qualities, and is particularly useful for magnetos and other electric instruments.

#### Anniversary of the Discovery of Petroleum.

Leslie's Weekly calls attention to the fact that it was slightly over 50 years ago, on August 28, 1859, that Edwin T. Drake, after months of untiring toil, first "struck oil" near Titusville, Pa. Petroleum had been found in springs in several parts of Pennsylvania before 1859, but Drake was the first one to specially bore for oil. In 1859 only 84,000 gallons of crude oil was produced, while in 1908 the world's product amounted to 6,000,000,000 gallons, of which 60 per cent, was produced in the United States.

## Approximate Wood Wheel Diameters for Various Sizes and Types of Rims.

The following table, which should prove very convenient to engineers and repairmen, has been compiled by the Firestone Tire and Rubber Company, of Akron, Ohio:

Size Tire.	Clincher and Universal.	Firestone Demountable.	Fisk Bolted On,	Pisk Demountable.	Continental Demountable.	Continental Demountable, Metric Sizes.

# New Vehicles & Parts

#### The Pierce "Thirty," Model K.

This new car has been placed upon the market by the Pierce Motor Company, of Racine, Wis., and is to be sold at a moderate price, \$1,750. The manufacturers have been building gasoline motors for a great number of years, and the car has, therefore, a great deal of motor experience back of it.

The motor is four cylinder, vertical, the cylinders being cast in pairs with integral water jackets. The bore is 4¼ inches, the stroke 5 inches and the rated horse power 30. The cylinders are mounted upon an aluminum crank case which contains all the working parts, and the bottom half of which holds the oil reservoir. By removing this bottom half access may be had to the crank shaft, cam shafts, gears, oil pump and connecting rods. The crank shaft is a heat treated drop forging with carefully ground bearings. All reciprocating parts are balanced, producing a quiet and smooth running motor.

Lubrification of all moving parts is by splash. The oil in the crank case is maintained at a constant level by a positive gear driven pump which takes oil from the reservoir and forces it into the crank case at all speeds of the motor. A Stromberg carburetor, with double adjustment, and Remy magneto with battery reserve provide for the mixture and ignition respectively.

The valves are large, taper seated and are placed in side pockets, the admission on one side and the exhaust on the opposite side of motor. All valves are easily removed for inspection or grinding. The push rods carry an adjusting screw and lock nut, and are fitted with a fibre washer to eliminate noise.

A positive and constant circulation of the cooling water is obtained by means of a gear driven pump. The honeycomb radia-

PIERCE "THIRTY," MODEL K, FOR 1910.

tor is claimed to be sufficiently large to cool the motor under the most trying conditions.

A multiple disc clutch, composed of thirtynine saw steel discs running in oil, transmits the power from the motor to the transmission. This clutch is claimed to engage with the greatest smoothness and to be positive in its action. Universal joints are placed between the clutch and transmission and between the transmission and drive shaft, to allow for any twisting of the frame due to unevenness of the road and to spring action. The transmission is selective, with three forward speeds and one reverse. Any speed may be engaged regardless of the others, and the reverse is locked and cannot be entered by accident.

The drive shaft is housed in the torsion tube and transmits the power to the differential gears housed in the rear axle. This axle is semi-floating and claimed to be of extremely strong construction. The front axle is a one piece drop forging of I section; it is the lowest point on the car, and has a clearance of 10 inches. The vehicle has a standard tread, 56 inches.

The front springs are semi-elliptic, 40 inches long, and the rear semi-elliptic, triple action, 50 inches long. The distribution of

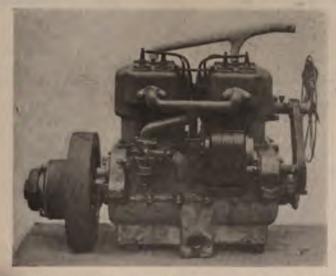

weight on the springs, combined with a wheel base of 112 inches, is claimed to give an extremely easy riding car.

The wheels are 34 inches in diameter and are equipped both front and rear with quick detachable rims and 4 inch tires. The rear wheels carry the brake drums upon which the four brakes act, one set expanding internally and operated by a hand lever, the other set contracting externally, operated by a foot pedal. The drums are 14 inches in diameter by 2 inch face, and both sets of brakes are powerful enough to hold the car on any grade.

The steering gear is of the worm and sector type, fitted with a 16 inch hand wheel which carries the spark and throttle levers. A foot throttle and muffler cut-out are supplied as well

The body holds five passengers without any crowding. No pains have been spared to make the upholstery and finish high class. The body and gear are finished in Brewster green, with hairline cream stripe; the wheels are cream yellow.

The equipment furnished with the car is generous, consisting of Rushmore gas head lamps, oil side and tail lamps, Prest-O-Lite gas tank, horn, robe rail, jack, tire repair kit and full complement of tools.

Admission side of motor, showing magneto, carburetor and clutch.

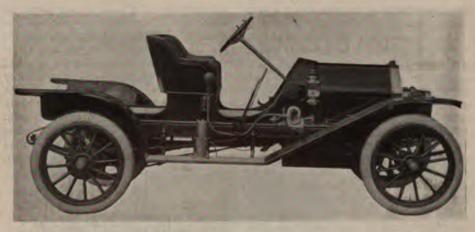

Exhaust side of motor, showing water pump.

PIERCE THIRTY HORSE POWER, FOUR CYLINDER MOTOR.

#### e New Overland Runabout.

unabout of entirely new design is produced by the Overland Automompany, of Toledo, Ohio. This new nade to sell at \$1,000, with either sindouble bucket rumble seats or with conneau. It is fitted with a four cylfour cycle, water cooled motor of the bore and 4½ inch stroke.

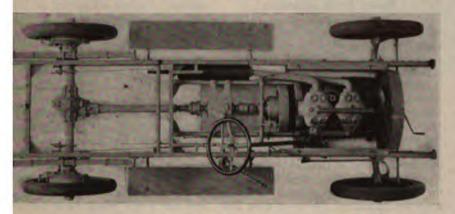

cylinders are cast separate with the all on one side and operated by a cam shaft. The cylinders are gray ough bored, left to season and then I to size. The valve seats and chams well as the cylinder heads, are ensurrounded by water, thus increasing oling surfaces. The spark plugs are I in the inlet chamber caps. The is taken into the cylinder water at the bottom on the right hand if the motor and discharged at the the jacket over the cylinder heads.

THE NEW OVERLAND RUNABOUT.

ly through the wall of the hollow pin—a piece of spring wire is twisted around the screw. This is accomplished by putting the straight piece of wire through the hole in The piston pin end is fitted with a phosphorbronze bushing, and is milled out on top to form a basin in which to catch oil for lubricating the piston pin. The lower or crank shaft end is fitted with die cast bushings of special composition. Two studs screwed and riveted into the connecting rod proper hold the connecting rod cap, which is of the marine type. Shims are provided for taking up the bearings. The caps are held in place by castellated nuts and cotter pins. The lower connecting rod bearings are 1½ inches in diameter and 2½ inches long.

The valves have nickel steel heads, electrically welded to twenty-five point carbon steel stems. They are 1¾ inches in diameter; the stems are three-eighths inch in diameter, and both are ground to size. The valves are actuated by the cams through square lifters working in white metal bushed guides. The lifters are drilled and tapped in the top, and a hardened screw provided with a lock nut is inserted for valve adjustment. The cam shaft is fifteen-sixteenths inch in diameter, of high carbon

PIERCE MODEL K CHASSIS.

a system of circulation is used. The quantity of water used in the system prising, only 4½ gallons, and it is d that the motor never runs hot. A I tube radiator, together with a four ball bearing, flat belt driven fancetes the cooling system. The fant is supported on top of the gear rtment, and is independent of the or in every way. The belt is adjusted ans of an eccentric at the top of the racket. The fan is driven from a on the crank shaft, and runs two and ird times the speed of the motor, .

pistons are of the same material as linders, and are provided with three ric compression rings above the piston and three oil grooves below for dising the oil. The piston is flat on top as four ribs underneath the head, iston pin is three-quarters inch in dir. It is made hollow for the purpose ing lubrication, the hollow ends being resunk at a wide angle to offer as litstruction to the oil as possible, and o form the centres on which the pins round. The pins are of nickel steel, and ground to size.

piston pin is held in place by a sinrew with a hole in the top. After rew is in place its point passes entirethe top of the set screw and turning the screw several turns.

The connecting rod is drop forged of forty point carbon steel, and is of I section.

FRONT VIEW OF OVERLAND RUNABOUT.

steel, hardened and ground, with the cams forged integral, and three liberal bearings. The front bearing is 25% inches long; the centre 35% inches long and the rear bearing 23% inches long.

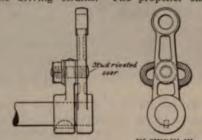

The crank shaft is a drop forging of forty point carbon steel. It is heat treated, and all bearings are ground to size. It has five main bearings, which are 1½ inches in diameter. Four of the bearings are 2½ inches long each, and the rear bearing is 3½ inches long. The crank shaft gear is of steel, with spiral teeth and keyed to the shaft. The gears, of which there are four, are housed in an oiltight compartment in the front of the crank case,

Lubrication of the moving parts is effected by means of a mechanical oiler, driven from the rear end of the cam shaft and by splash in the crank case. A stand pipe is provided by which to gauge the oil level in the crank case. The crank case is cast from an aluminum alloy in two parts, the upper portion containing all the crank shaft bearings, which are independent of the lower half. The lower half serves simply as an oil pan. Drain cocks are provided in the bottom of the lower half for drawing off the oil when desired. The flywheel is of cast iron, with fan spokes, and in the coupling attached to the flywheel is the only universal joint in the propeller shaft line.

The motor has a three point suspension, two points of support being at the rear and one under the centre at the front. Located in the centre of the inlet manifold is the Schebler carburetor, which is quite accessible for adjustment. The cylinders are offset from the centre of the crank shaft to reduce the angularity of the connecting rods on the power stroke.

The cross member of the frame immediately back of the motor deserves particular mention, since it forms the forward support of the propeller shaft and torque tube. This member is of malleable iron, and combines

the functions of a large number of pieces. Right here it may be added that there are no holes in this frame except those used for the frame rivets. The torque tube is attached to this cross member by a yoked swivel joint. At this swivel joint, between the propeller shaft and the flywheel, is the only universal joint in the propeller shaft. Two strong truss rods run from this point back to the rear axle brake flanges, holding the rear axle in alignment and transmitting the driving strains. The propeller shaft,

BRAKE LEVER ASSEMBLY.

between the universal joint and the change gear, is supported on roller bearings inside the torque tube. The change gear, which is planetary, is located on the rear axle, and is operated entirely by pedals. It is so arranged that by applying the slow speed the high is automatically released and vice versa. The only hand lever to operate is the emergency brake lever, the entire control being by pedals. One pedal operates both the low forward speed and the reverse; another pedal the high speed and a third the brake, making three all told. The change gears run in oil, and the direct drive gear shaft is carried on annular ball bearings. The high speed clutch is of the plate type, and can be tightened or loosened through a hand hole with the fingers. The direct drive bevel pinion is keyed to the direct drive shaft, and meshes directly with the large bevel driven gear on the differential

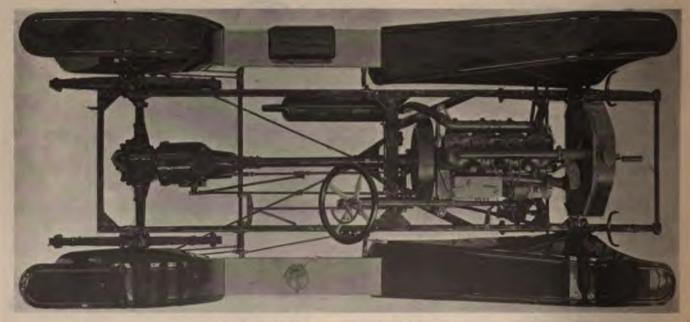

casing. The differential is of the bevel pinion type, and is supported on roller bearings, with ball thrust bearings on both sides. The axle shafts run on roller bearings, and the wheels are fitted to them by means of a taper, key, nut and lock nut.

The front axle is a one piece drop forging of I section. The spring pads are milled to conform to the shape of the spring and are forged integral. The frame is of pressed steel of 334 inch channel section, 134 inches wide and five-thirty-second inch thick. It is strongly braced, the braces to the centre member of the frame forming the rear supports for the motor. The radiator is carried above the front cross member on two artillery trunnions, which, by allowing a slight swinging motion, entirely frees the radiator from all strains due to road shocks. With merely two bearings to remove the task of dismounting the radiator is an easy one, since it is held in position by only four cap screws. The radiator brackets are carried on the upper part of the frame, and the same castings also carry the lamp brackets and fenders. A front bar extending between the springs prevents swaying, and serves to protect the lamps and the radiator, as well as to add strength to the forward portion of the frame.

The 16 inch steering wheel works through a worm and gear. The gear is a full wheel, so that by removing the steering arm and turning the steering wheel three complete revolutions a new bearing surface is obtained. There are ball thrust washers both above and below the worm. The ball and socket joints are so designed that it is impossible for them to loosen and for the rod to drop off.

The wheels are of the artillery type, with twelve 11/4 inch spokes and 32x31/2 inch tires. The wheel base is 102 inches and the tread 56 inches.

The brakes are internal expanding and

OVERLAND RUNABOUT-PLAN OF CHASSIS.

external contracting, respectively, both operating through equalizers to the rear wheel brake drums. The main brake shaft has a long bearing in the upper portion of the rear step hangers, which not only makes the operation of the brakes firm and easy but greatly adds to the strength of the step. The provision for adjustment of the brakes is unique. It consists of a small pad on the side of the brake lever, which has ratchet teeth milled in its face, and teeth to coincide on the lever, and advancing or retarding this lever tightens and loosens the brakes. This arrangement is locked in place by a nut and lock washer. The internal brakes, operated by a hand lever at the driver's right, are the emergency brakes. The external brakes, operated by a pedal, are the service brakes.

The front springs are semi-elliptic, 36 inches long and 134 inches wide. The rear springs are double scroll full elliptic, 36 inches long and 134 inches wide.

The spark and throttle control lever are located on a stationary quadrant on top of the steering wheel. The dual ignition system, with a single set of spark plugs, is used, the batteries working through the magneto distributor.

Dark blue is the standard color. Each car will be equipped with two gas head lights, two side oil lamps, one oil tail lamp, generator, horn, tire pump, tire repair kit and full tool kit. The cars are ready for immediate delivery.

#### Improved Line of Hoyt Pocket Meters.

So widespread has the use of batteries become that the demand for small pocket meters with which to test them has grown to considerable proportions. The Hoyt Electrical Instrument Works, of Penacook, N. H., early recognized the importance of this field, and have just added a line of immeters and voltmeters approximately the size of a gentleman's No. 16 watch, the novel feature of which is a silver plated metal scale, which is claimed to combine accuracy, durability and tastiness in design.

Realizing that the first requisite was a careful standardization of every part, they have for some time been working along these lines, and they claim to have designed

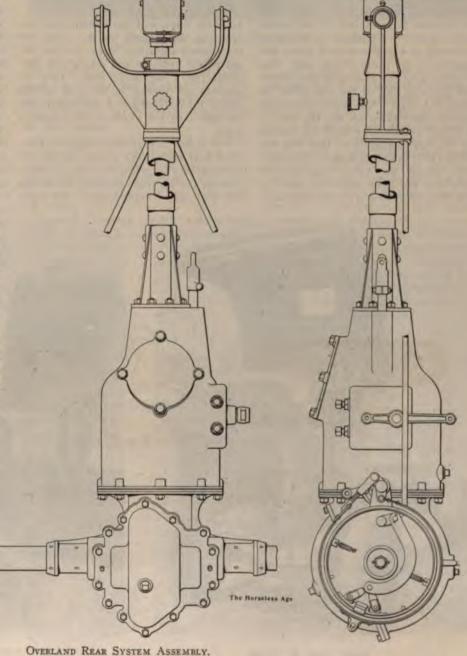

every part so carefully that exhaustive tests have failed to show any material error in any part of the scale.

These meters are of the permanent magnet type, and in designing them the purpose of their use has been constantly kept in mind. The relation of the moving system to the poles of the permanent magnet is said to be such as to insure a practically dead beat movement, with extreme sensitiveness to current changes. The case is substantially made in one piece to insure rigidity and mechanical accuracy,

A novel design of lettering has been adopted for the dial, and it is the purpose of the makers to carry out the same idea in all instruments of this type to readily distinguish them from other meters of somewhat similar, general appearance.

The United States Motor Truck Company, a newly organized concern of Cincinnati, Ohio, has elected the following officers: Alfred Hill, president; Herman Erdman, vice president; Harry L. Manss, treasurer, and Jesse Lowman, secretary. The company is at present looking for a suitable factory.

#### The Gramm-Logan Motor Trucks.

Only very slight changes have been made on the Gramm-Logan trucks manufactured by the Gramm-Logan Motor Car Company, Bowling Green, Ohio. The changes made are designed to secure greater accessibility of the different parts without sacrificing loading space. The company build heavy 3 ton trucks, buses and light delivery wagons of 1,500 pounds capacity. Since there are but slight differences (except as to size) in the chasses of the different types it will suffice to describe the 3 ton car.

The motor is a four cylinder, four cycle, water cooled one. The cylinders are of gray iron, cast in pairs, with the valves all on one side. The bore is 43/4 inches and the stroke 5 inches. The cylinders are offset from the centre of the crank shaft. Cooling is effected by means of a centrifugal circulating pump, a ball bearing, belt driven fan and a tubular radiator, the radiator being located at the extreme forward end of the frame and protected by a bumper. Lubrication is effected by a self contained pump and reservoir in the lower crank case. The oil pump is of the gear type and driven from the rear end of the cam shaft, as is also the timer. The water pump and magneto are located on the left side of the motor, and between these are located two oil supply gauges, so that one can readily tell if the oil is properly flowing.

The pistons are extra long and are made from the same quality of metal as the cylinders. They are fitted with four

GRAMM-LOGAN MOTOR OMNIBUS.

eccentric rings, with lap joints, which are returned and ground on the sides and the bearing surfaces. They are then fitted to the cylinder and piston and subjected to a tightness test. Five oil grooves are turned in the side of the piston for collecting and distributing the oil splash to the inside of the cylinder walls.

The crank shaft is drop forged of alloy steel, heat treated and ground to size. It is fitted with centrifugal oil rings, which prevent the oil from working out of the end bearings. Thrust bearings are fitted on both the front and rear ends to take up the thrust of the clutch. The connecting rod is a drop forging. The bearing caps and bushings are retained with two nickel steel bolts, which are secured with a special locking device. The cam shaft is also a drop forging, with the cams forged integral, and has three white bronze bearings, which are lubricated from oil pockets in the crank case. The exhaust manifold and intake are both located on the same side, and are held in place by the same studs and clamps.

The carburetor is located on the right

FRONT VIEW OF TRUCK.

FRONT PORTION OF TRUCK,

hand side of the motor and in the centre of the intake manifold. The dual system of ignition is used with a single set of spark plugs, using a Splitdorf magneto

and a storage battery.

The crank case is of aluminum alloy, in two pieces. The gears are located in an oil tight compartment at the front end of the motor, which is cast integral with the upper portion of the crank case. The lower portion contains the two end bearings of the crank shaft and the oil res-

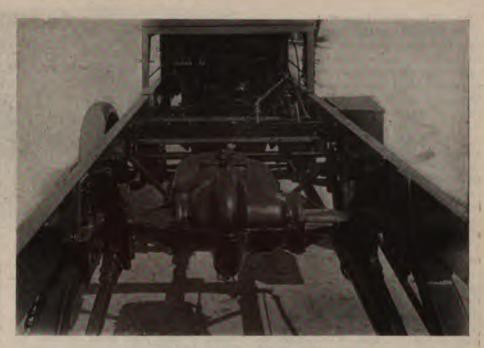

ervoir and pump. The clutch is composed of thirty-four steel discs, seventeen large and seventeen small ones, which run in oil. This member is contained in a round case bolted to the back of the motor flywheel. Between the clutch and the change gear is located a double universal joint of the block and trunnion type. The gear set is of the progressive gear type, with three speeds forward and reverse, and enclosed in a malleable iron case, together with the jack shaft and differential. Timken roller bearings are fitted throughout. gears are of nickel steel and hardened. The gear ratio on the high speed is nine to one at the rear wheels. The differential is of the bevel pinion type, and is supported on Timken bearings, as are

also the outer ends of the jack shaft. The sprockets on the jack shaft are thirteen or fifteen teeth, 11/2 inch pitch and eleven-sixteenth inch thick. The rear wheel sprockets are forty-two teeth malleable castings, of 11/2 inch pitch and eleven-sixteenth inch thick. Diamond speeds forward and reverse, and enclosed in a malleable iron case, together with the jack shaft and differential. Timken roller bearings are fitted throughout. The gears are of nickel steel and hardened. The gear ratio on the high speed is 9 to 1 at the rear wheels. The differential is of the bevel pinion type and is supported on Timken bearings, as are also the outer ends of the jack shaft,

The sprockets on the jack shaft are 13 or 15 teeth, 11/2 inches pitch and elevensixteenths of an inch thick. The rear wheel sprockets are 42 teeth malleable castings of 13/2 inch pitch and eleven-sixteenths of an inch thick. Diamond chains are used for the drive to the rear wheels. They are of 11/2 inch pitch, three-quarters of an inch roller and three-quarters of an inch wide.

There are two sets of brakes. The service or foot brakes operate on the jack shaft drum, while the emergency or hand brakes are internal expanding and operate on the rear wheel brake drums. The car is guided by a 20 inch steering wheel, underneath which are the spark and throttle control levers.

The motor is located at the very forward end of the frame and directly beneath the driver's seat. The gasoline tank is located under the seat proper and holds 18 gallons. The rear axle is made of 31/4 inch solid round machine steel, with very large Timken bearings on the spindles. The front

REAR VIEW OF GRAMM-LOGAN TRUCK CHASSIS.

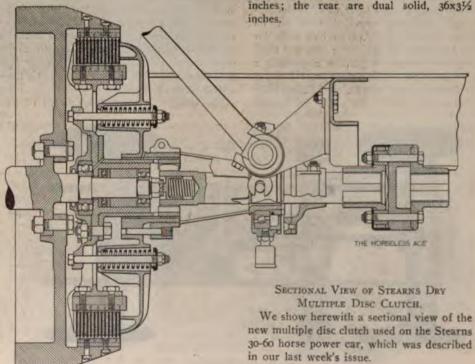

axle is of high carbon steel, yoked at the ends for the steering knuckles. It is 21/2 inches square. The spindles are also fitted with Timken roller bearings, which carry the front wheels.

The frame is constructed of 5 inch steel of channel section and joined at the corners by steel castings, and riveted with five-sixteenth of an inch rivets. The loading space is 5x11 feet and the wheel base 120 inches.

The front springs are semi-elliptic and are hung from the frame by steel castings and steel bolts. The rear bolts pass

through rollers which are of 21/2 inch outside diameter and a little over three-quarters of an inch inside diameter These rollers take the place of shackles as ordinarily used. The springs are 40 inches long and 31/2 inches wide and have nine leaves; they are fastened to the axle by steel castings and clips. The rear springs are of the platform type and are hung the same as the front springs, except that the rear cross member is connected to the side members by shackles and shackle bolts.

Either pressed steel or artillery type wheels are furnished, with felloes full width of the rim. The tread is 66 inches. The front tires are solid singles, 36x5 inches; the rear are dual solid, 36x31/2

The 1910 Hupmobile.

The Hupp Motor Car Company, of Detroit, Mich., have just made public the features of their new model for 1910, known as Model B. The car retains the same lines as the original Hupmobile model, but has been improved in several details, as will appear from the following description.

The wheel base is 86 inches, the tread standard, and the car is fitted with 30x3 inch G & J tires. The minimum road clearing is 11 inches, which is under the axles, while the flywheel clears the road by 13 inches. Among the improvements in the new model is the adoption of an oval gasoline tank mounted on the body with its greatest diameter vertical. This tank has a capacity of 11 gallons, and is arranged back of the seat in such a position that there will be plenty of head for feeding gasoline to the carburetor even on the steepest hills. The weight of the car complete is given as 1,100 pounds, and its speed range as up to 50 miles per hour. The price of the car, with an equipment including oil lamps, tools, etc., is \$750.

The four cylinder motor is of 31/4 inches bore by 33% inches stroke, and is rated at 16-20 horse power. The crank shaft, which is made from 30 point carbon steel, is 11/4 inches in diameter, and is offset threeeighths of an inch from the centre of the cylinders. To a taper seat at the forward end of the shaft is keyed a 40 pound flywheel of 14 inches diameter, which is cast with fan blades. The connecting rods are I section drop forgings. The rods are bushed with Parsons bronze, and the caps are provided with oil scoops to insure lubrication of the crank pin bearings. The piston pins are hardened and ground, and are fastened in the rod by cone-pointed set screws, while they have their bearings in the piston bosses. The pistons are 3% inches long, ground taper to allow for unequal expansion, provided with an oil groove seven-eighths of an inch wide for the lubrication of the piston pins and fitted with three eccentric packing rings with a 45 degree joint. The valves are 11/2 inches in diameter, bevel seated, of the electrically welded type. All of the valves are located

HUPMOBILE 1910 MODEL

on the left side of the motor. The spark plugs are located over the inlet valves and the priming cups over the exhaust valves. The inlet and exhaust manifolds are made of cast iron, and are held in place by four clamps, a tight point being obtained by means of copper-asbestos gaskets. Provisions are made for admitting warm air from around the exhaust manifolds to the carburetor whenever the weather is cool, but in warm weather cold air can be admitted directly by the removal of a 1 inch pipe plug.

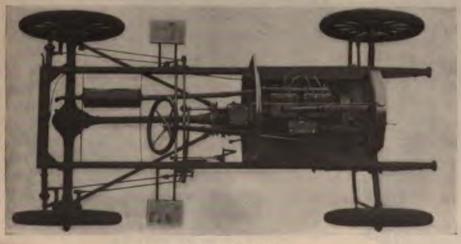

The cam shaft is made integral with its cams, and is hardened and ground. It is babbitted in place in a cast iron side plate extending the full length of the motor, as shown by one of the illustrations herewith. When this plate is removed free access is obtained to the connecting rods. This shaft is carried in five bearings which are lubricated by the splash in the crank case. The valve push rods also have their bearing in this plate. These push rods have their lower ends, where they make contact with the cams, milled on a radius, so as to give substantially the same effect as is obtained with a roller, and fibre blocks are inserted in the upper ends where contact is made with the valve stems. The cam shaft gear is of gray fibre reinforced with steel, and meshes with a steel crank shaft pinion.

The ignition is effected by means of a

Bosch high tension magneto, which is mounted on a ledge on the side cover and driven by an enclosed gear on the armature shaft, which meshes with the cam shaft gear. The spark timing is fixed. Ignition is controlled by means of a cut-out switch on the dashboard.

The engine is oiled by means of splash in the crank case. Oil pockets are provided over the crank shaft bearings and the bearings in the change speed gear. The oil working through the front crank case bearing is returned to the crank case by means of a return drain. The crank case is divided into two compartments, each of which has a drain cock. Oil is fed to these compartments by an oiler cast integral with the inlet water lead. The oiler is of such construction that its feed automatically increases with the opening of the throttle valve, and is stopped entirely when the throttle is closed. The thermo-siphon system of circulating the cooling water is employed, and about 3 gallons of water is carried. The radiator is of the same general construction as last year, but the number of vertical tubes has been increased from four to five, and the intermediate tank has been increased in size. The radiator is now provided with a filler tube of slightly curved taper, which is considered to improve the outline. The water flows from the top of the cylinder jackets to a tank 8 inches from the top of the radiator, extending half way through and not visible from the front. It is stated that the fact that the hot water returning from the motor must pass through radiator tubes 4 inches long before it reaches the top of the radiator prevents the escape of steam. The speed of the motor is ordinarily controlled by an accelerator pedal, and there is also a throttle lever underneath the steering wheel.

One of the most important changes in the new model Hupmobile consists of the adoption of a multiple disc clutch. The latter consists of nine saw blade discs, and is enclosed in the change gear case, so that it runs in an oil bath. The latter case is made of cast iron and bolted to the rear end of the crank case, as seen in the illustration. The change speed gear is of the sliding type, with two forward speeds and

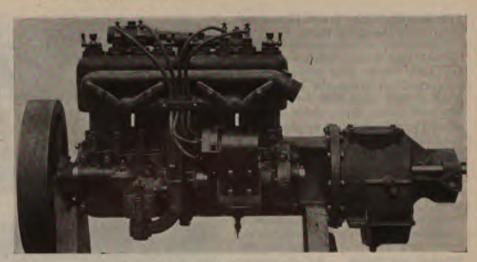

PLAN OF CHASSIS.

one reverse. It is possible to move from the neutral position directly into any forward position or the reverse. The gear raties for the low forward and the reverse gears are the same, the ratio of reduction from the high speed being 2.7 to 1. The gears of the change gear are made from 20 point carbon steel and are case hardened. In the rear end of the gear case there is a large cylindrical bearing which fits over the spherical housing of the propeller shaft, providing a dustproof joint, and at the same time taking up the torsion of the rear axle drive. Two radius rods extend diagonally from the rear brake support to sockets in the gear case.

The rear axle housing consists of 2½ inch steel tubing with ½ inch walls. These tubes are pressed and riveted into the bevel gear housing. The rear axle shafts are 1½ inches in diameter, and are carried on Hyatt roller bearings at the wheel ends, and two point ball bearings at the inner ends. The driving pinion and the differential pinion are of 3½ per cent. nickel steel, case hardened. The gear wheels are of 30 point carbon steel, also case hardened. The bevel gears have 12 and 48 teeth respectively. The bevel pinion is electrically welded to its shaft, which latter is supported on New Departure ball bearings.

A rather important change has also been made in the design of the front axle, which

LEFT SIDE OF MOTOR AND GEAR BOX.

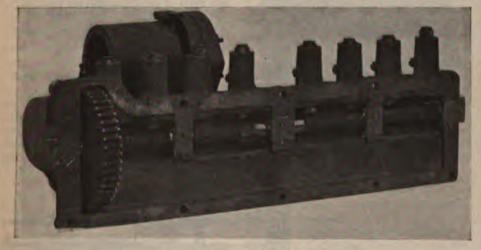

these sockets encloses a coil spring designed to absorb road shocks. It is claimed that with this steering mechanism the play of the springs has no perceptible effect on the steering wheel. The steering gear housing is riveted to the front cross member of the frame.

A single cross spring is used at the rear which is of the inverted double sweep type, and has a ball socket clipped to it in the middle for taking a ball ended bolt that seats in a bracket in the middle of the rear frame member, thus affording a three point

The method of holding this tread on the tire differs considerably from that of the well known Woodworth adjustable tread. A number of galvanized steel plates are riveted along each side of the tread a short distance apart, connected by short and very stiff springs. Each spring is linked to one end of the plate and has a hook on the other end. The tread is applied by slipping it sidewise over the deflated tire with the springs unhooked. After the tread is in place the springs are hooked, connecting the plates and forming a ring on each side. As the tire fills out the springs are stretched, holding the cover tight on the tire, and always ready to take up any slack.

Besides the new adjustment, the improved self-adjusting treads have the leather treated by a new process which, the makers state, they found by experience to double the life of the leather, preventing the action of dirt and water from affecting it. The new leather is of a very dark green color.

The rivets used in the middle of the protector have thicker heads than have been used in other treads, adding greatly to the mileage. They have the corners rounded off so that they cannot be caught in such a way as to be forced out of the leather. The leather on each side of the heavy rivet is studded with flat head rivets which do not materially increase the weight, but protect the leather in ruts or on rocky or stony roads.

CAM SHAFT AND HOUSING.

is now an I section drop forging made from 40 point carbon steel and heat treated. The steering heads are forged integral with the axle itself. The steering spindles are drop forgings 1 th inches in diameter, and are provided with two point adjustable ball bearings.

The car is equipped with two double sets of brakes, both of the internal expanding, cam-actuated type, mounted side by side on the rear wheel hubs. The brake shoes are faced with Thermoid brake lining. One set of brakes is operated by a pedal and the other by a hand lever. The steering gear is of the rack and pinion type. The race has a straight line connection with the axle steering arm through a drag link with heavy adjustable ball sockets at both ends. One of

support. The eyes of the spring are pivoted to sliding journals which have a bearing on a cross bar parallel with the axle, and are supported by arms extending rearward from the brake support. Back of each of these journals is a compression spring which exerts a pressure outward, thus tending to deflect the cross spring and having a retarding effect on the rebound. In front the frame is supported by 34 inch semi-elliptic springs shackled at the rear end.

#### The Woodworth Treads for 1910.

The Leather Tire Goods Company, Niagara Falls, N. Y., have just brought out a new style of tire for 1910 called the Woodworth improved self-adjusting tread.

THE WOODWORTH TREAD.

## The Saurer Motor Truck Fitted for

a Dumping Body.

This machine is conservatively rated at between 3 and 5 tons. The wheel base is 153 inches and the tread 64 inches. The front wheels are 36 inches in diameter and carry 41/2 inch single solid tires. The 42 inch rear wheels carry double 41/2 inch tires. The motor is a four cylider, 41/8x51/2 inch, and rated at 30 horse power, foreign rating. It is fitted with the Saurer compressed air self-starting device and also with a motor braking attachment. The self-starting device is of that type in which air is admitted through a special valve on every working stroke. Transmission is through a cone clutch and a four speed selective gear box to a countershaft, and thence by side chains.

The construction of the dumping device is quite clearly shown in the photograph. The body is pivoted to the rear of the chassis frame, and the tilting is accomplished by a rather ingenious double telescope screw operated by a crank on the left of the chassis. The construction is as follows: The lower and larger screw is revolved in a stationary nut by means of a bevel gear feathered to it, and which is revolved in turn by another gear affixed to the hand operated crank shaft. The casing which encloses the bevel gear is arranged to allow a slight movement around an axis which is common to the transverse crank shaft. Inside the main screw is another which is threaded oppositely to the main one, and which is secured at its upper end to the body frame in such a manner as to prevent its revolution, but to allow of a slight fore and and aft movement around the axis of the bolt which secures it. It will be seen that as the main screw revolves in its nut in such a direction as to raise itself the upper screw will revolve in the threaded hole of the main screw and will be raised relative to the main screw. This

SAURER TRUCK WITH DUMPING BODY FRAME.

device is much more compact than a single screw for the purpose. In practice the screws are protected with a telescoping canvas covering which was removed to show the construction more clearly.

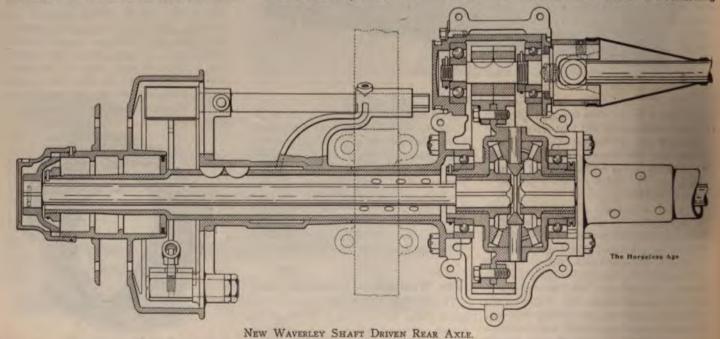

#### The New Drive of the Waverley Company.

In our issue of October 6 we described the new electric models of the Waverley Company, of Indianapolis, Ind., which are characterized by a new shaft drive. We show herewith a sectional view of the rear axle and driving gear. As will be seen from this cut, a shaft from the motor, which is hung from the vehicle frame, extends crosswise of the chassis and connects throught compact universal joint with the shaft of the driving pinion. The driving pinion as well as the differential gear is carried in annular ball bearings. The driving gears are of the herringbone type, which insures noiseless operation. The rear axle

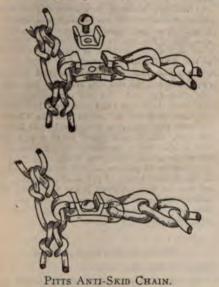

construction is of the floating type, an adaptation from gasoline vehicle practice. The rear wheel hubs run on the outside of the axle tubing on Timken roller bearings, which are not shown in the drawing. It will be noticed that the brake drums are integral with the hubs. The driving gear is, of course, set to one side of the centre of the rear axle so as to make the propeller shaft as long as possible and reduce the action and wear of the universal joints. The side gears of the differential are fitted to the rear axle shafts with square joints, and the shafts may be withdrawn without disturbing the other parts of the axle.

#### The Pitts Anti-Skid Chain and Connections.

The Pitts Anti-Skid Chain Company, 2422 Michigan avenue, Chicago, have placed on the market a new tire chain in which the cross chains are connected in a novel manner. The cuts show one of the connecting

members open and closed. This member is simply a double ended hook, and is closed by bolting to it a U-shaped piece of metal made to fit the opening in the hook. The ease of replacing worn or broken cross

chains and the possibility of adding extra ones when the going is unusually bad are among the advantages claimed by the makers. The simplicity of the device is also claimed to be a strong point in its favor. The cross chains are hardened and copper oxidized to prevent rusting. After the chains are worn, and have in consequence become slack, they may be tightened by putting on more cross chains. The chain links are electrically welded. These chains come put up in canvas bags, and a number of extra cross chains are furnished with each set.

#### To Make Auto Fenders.

Another industry was added to the long list of concerns engaged in making automobile accessories by the incorporation of the Welton Auto Fender Company, with a capital of \$20,000, under Ohio laws. The company has opened an office in the Columbus Savings and Trust building, Columbus, Ohio, and a factory may be located there at

WELTON AUTO FENDER.

a later date. The corporation holds the patents to an automobile fender which is claimed to aid in protecting the lives of pedestrians and also preserve motor cars from serious injury in accidents. The company has equipped a number of cars with

the device, which consists of a strong steel frame covered with a heavy cushion of rubber. The device is adjusted in such a manner to the front of the car as to cast aside any persons that might be struck. The incorporators of the company are D. J. Welton, George G. Welton, J. W. Howe, H. H. Ebright and S. W. Gilliland.

#### The Alexander Wind Brake.

The J. Alexander Company, 1931 Broadway. New York, are manufacturing a wind "brake" or shield, which is something of a novelty in accessories of this class. As the cut shows, the "brake" is a screen of fine wire mesh, 14 inches in diameter, attached to the steering post, which serves to protect the face of the driver from sand, dust, insects, and break the force of the wind. At the same time the air resistance involved in its use is not so great as in the case of a glass shield of the some size, for instance. The appliance is regularly furnished with a dull gun metal finish, which obviates the dazzling reflections which might be encountered if a nickel or bright brass finish were used. Among the advantages claimed for

THE ALEXANDER WIND BRAKE,

this shield over the ordinary glass shield are less air resistance, no reflections and less liability of breakage.

#### New Six Cylinder Roadster to Be Made in Detroit.

The latest addition to the numerous types of cars made in the centre of the American automobile industry is to be known as the Anhut Light Six-Thirty-Six, which will be made by the Anhut Motor Car Company, whose incorporation is reported in another part of this issue. The first car of the company made its appearance on the streets of Detroit last week. It is a powerful light roadster of pleasing lines, and is claimed to develop a speed of 60 m. p. h. The company is headed by Senator John M. Anhut, who is its president, and the other officers are: Mayor Philip Breitmeyer, vice president; Charles Lansby, treasurer, and H. H. Thorpe, secretary. The company has secured a factory at 206-212 Howard street, abutting on the Michigan Central Railroad, which covers an area of 70x300 feet. The car is to sell at \$1,600, and it is planned to turn out from 500 to 1,000 for next year.

#### Dealers' Number of Rambler Magazine.

The last issue to hand of the Rambler Magazine, published by Thomas B. Jeffery & Co., of Kenosha, Wis., is a special Dealers' Number, and is a very creditable production. It is printed in colors on heavy coated paper, and is profusely illustrated with touring scenes, factory views and illustrations of the new Rambler models. The book contains a picture of the Rambler factory, claimed to be the largest automobile plant in the world, a portrait of Thomas B. Jeffery, the announcement of the new Rambler, the details of all the special Rambler features, an illustrated story of the methods of making and testing of Ramblers, a story of the sales organization, and the record made by this concern during the past nine years. Copies of the issue are sent free to all dealers upon request.

Diamond Rubber Company Doubles Capital.

The stockholders of the Diamond Rubber Company of Akron, Ohio, recently received a stock dividend of 100 per cent., which doubled their holdings in the company. A paper was filed with the Secretary of State of Ohio increasing the capitalization of the company from \$5,000,000 to \$10,000,000. In addition to the stock dividend a cash dividend of 10 per cent, was declared. The stock dividend is the second of its kind, as in 1907 a dividend which increased the capital from \$3,500,000 to \$5,000,000 was declared. Previous to the stock dividend the stock sold at \$340 a share. The company operates the Bryant Steel Wheel and Rim Company in Columbus besides its tire plant in Akron.

Dispute Over Factory.

An interesting controversy has arisen over possession of the former plant of the Standard Wheel Company, in Indianapolis, which is occupied by the Parry Automobile Company. The C. M. Krouse Company claims that it has a lease on the building, although the automobile company leased it for ten years recently. Employees of the Krouse Company attempted to move machinery into the building a few nights ago, with the result that four of the men were arrested for malicious trespass. The question of the lease will be settled in the courts soon.

Arrangements are being made to inaugurate on December 1 a motor mail between Edinburgh and Glasgow, one van leaving Edinburgh at 10:35 p. m. and arriving in Glasgow at 6 a, m., while another will leave Glasgow at 9:30 p. m. and arrive at Edinburgh at 3:30 p. m., each making one trip daily.

#### Tire Tread Construction.

Editor Horseless Age:

One of the most serious problems which at present confront the motorist is that of reducing the expense of renewing the tires. For years the price of rubber has constantly advanced, and with it the price of tires, and with the rapidly increasing number of automobiles it does not seem likely that there will be any reduction in tire prices unless the production of rubber is enormously increased.

I would like to ask if you or any of your readers can inform me whether any substitute has ever been proposed for rubber in the manufacture of the shoes or outside portions of the tires. While it is true that there is probably no substitute for rubber for manufacturing the inner tube, it seems to me that inasmuch as the entire strength of the shoe or outer case depends upon the fabric of which it is constructed, and the rubber is incorporated with the fabric mainly for the purpose of protecting it from the action of water, some substitute for rubber might be used which would be very much less expensive and almost equally efficacious. I understand that there have been a good many arguments put forward to prove that the rubber incorporated in the fabric prevents the threads of the fabric from wearing each other out, but in spite of this it is a well known fact that with a great many tires the fabric does wear out on the inside, while from the exterior the case does not show any very serious evidences of wear.

Would it not be possible, therefore, to construct a case on the lines of the familiar cotton fire hose, only having a number of extra plies woven or incorporated upon the threads thereof, and to impregnate the whole structure with some substance like linseed oil, in the manner now used in the manufacture of oilskin clothing? There are processes of weaving which can produce a structure of this sort, having all of the plies of fabric united into an integral structure, and it would seem that even if such a tire did not possess the wearing qualities of the rubber tire now universally used, it might be very much cheaper to manufacture, so that the expense of renewal would be much less in proportion to the amount of mileage. Anyone who has worn oilskins is aware of the fact that they do not tend to dry hard or to crack with age, but, on the contrary, often become very sticky, and are not lacking in flexibility, although, of course, a structure such as I suggest might not be quite so flexible as the present case.

It would seem to me that some experiments along these lines might prove interesting, and, in view of the advancing price of rubber, are well worth trying, though

eventually it might be necessary to construct the tires along different lines than tires are at present constructed.

ARRAHAM B. COX.

[You are probably aware of the fact that one or two foreign tire manufacturers incorporate steel studded leather bands, comprising three thicknesses of leather, in the tread of the tire. The object of this construction is, of course, not so much to cheapen the manufacture of the tire nor to increase its durability, but to secure nonskidding qualities without appreciably reducing the resiliency. A tire (single tube) built on those principles was manufactured a number of years ago by a rubber concern in New York city, but did not prove a success. This, of course, is not conclusive proof that the principle is not adapted for use in tire construction. We are not in position to judge the practicability of the construction described by you, and believe that only an actual test could determine its value.-ED.1

## What Put the Columbia Car Out in the Fairmount Park Race.

Editor Horseless Age:

We have noted in the various automobile trade journals that the accident which put the Columbia out of busines in the Fairmount Park races in Philadelphia on October 9 was passed over, leaving the readers to surmise that the car broke down on account of some particular weakness. We do not ask that any excuses be made for the Columbia, but we believe that it is only fair that a correct statement of facts be given, the same as in other accidents which were fully described. To that end we are enclosing herewith a copy of an article that appeared in the Philadelphia North American, issue of October 17, which is correct in every particular except that it states that Coffey went out of business during the third lap. The accident occurred during the second lap, as he had gone from fourteenth to eighth place when he passed the grand stand on the first lap. We would be pleased to have you give the car the credit of going out of business through no fault of its own. The statements in this article can be easily proven by the driver and mechanic in the Chadwick car, which was fortunate enough to finish.

THE COLUMBIA MOTOR CAR COMPANY,
Per H. W. Nuckols,
Vice President and General Manager.

#### (ENCLOSURE.)

It does not seem to be generally known just why the Columbia car discontinued running after the third lap during the recent park race. After making two laps Coffey had gone from fourteenth to eighth place with the Columbia. He was going up City Line Hill toward the turn at Belmont avenue. Preceding his car was the Chadwick, driven by Perkins.

The Chadwick turned at the sharp angle going on to Belmont avenue, and raising considerable dust at this point. In going round this point, however, his car skidded, so much so that it partly faced about in the opposite direction and blocked off the road so that there was no room to get around him without striking the car or the tree, or else running into the people.

At this point Coffey showed wonderful nerve

and quick foresight. Knowing that he would strike both he ran between the car and the tree and cut a gash in the tree 1½ inches deep with his hub cap, and also striking the Chadwick car. The damage to the Columbia was principally done by striking the tree, as this was an enormous shock.

It did not, however, break anything except to throw the rear axle out of line and bend the frame. The car could still proceed under its own power, but was in no condition to finish the race, and Coffey decided to abandon it as soon as the grand stand was reached.

In this accident the Columbia had the tires ripped off, and the two cars after this laid side by side along the road. Another car following these two would have run right into them had this car not been flagged. It appears that the Chadwick car took the turn very fast, too fast to keep on the road, and it was placed in such a position that it was utterly impossible to get around the car at the speed Coffey was going.

A number of persons at this turn have spoken

A number of persons at this turn have spoken in the highest terms of praise about Coffey, stating that he deserves great praise for saving lives, both of the spectators and those in the two cars. This same car, however, will enter the Vanderbit race, and Coffey will drive.

#### How to Correct a Skid.

Editor Horseless Age:

To settle an argument, and possibly save some future trouble, will you kindly advise through your columns, or otherwise, what would be the proper thing to do under the following circumstances: Suppose an automobile to be passing over a wet, slippery, asphalted street. Suddenly the rear end of the car skids smartly in the direction of right hand curbing. Should the steering wheel be turned to the right or to the left under such circumstances in order to straighten out and go ahead. Should the brakes be brought into use?

#### A REGULAR READER.

[We submitted this question to our contributor, H. H. Brown, who replies as follows: "The general rule in case of a skid is to steer slightly in the opposite direction from which the skid tends to head the car. As to the use of brakes, the general rule is to use them sparingly, if at all, where skidding occurs or is likely to occur, but rather to allow plenty of time and let the car speed die down gradually and to use a brake which acts on the rear wheels direct and not on the differential or propeller shaft. In the case in question, where the rear skids toward the right curb, the machine will be headed toward the left. Therefore, following the rule, the wheel should be turned to the right. The only exception to this would be in the case of a tendency for the car to move bodily to the right owing to excessive crowning of the road. In this latter case it might possibly be advisable to steer to the left to regain the crown, although even in this instance the skid will probably have altered the direction sufficiently for this purpose.

"As to the use of the brake, it is questionable whether in this instance it is wise to even throw out the clutch or slacken the speed of the motor, for it is necessary to get the machine moving in the direction of its length before it can be steered to the right to be straightened out. As soon as

the car is moving in the direction of its length and properly answering the wheel, then, of course, the clutch may be thrown out and the brake applied with judgment, if necessary. The three rules to be observed on slippery streets are: Steer small, use brakes sparingly, if at all, and either keep far enough away from the curb, so that in case of a skid the machine will not strike it, or keep as close as possible, so that in case it does strike the momentum of the car toward the curb will be small and the blow glancing."—ED.]

#### Turbine Automobiles.

Editor Horseless Age:

Has anyone ever attempted to build an automobile, gasoline or steam, with a turbine engine? If not, why not?

G. B. ROBERTSON.

[We know of only one attempt to build a steam motor car equipped with a turbine. This was a heavy truck which was equipped with a boiler, steam turbine-electric generator set and electric motors, but the regular manufacture of these trucks was never begun, although the first machine seemed to be quite successful. The reason that steam vehicles are generally fitted with reciprocating engines instead of turbines is that the reciprocating engines, if well made, are thoroughly satisfactory, and if of the compound type and designed to be operated on superheated steam they are probably more economical of steam than a turbine could be. Besides they do not require an extra speed reducing mechanism like the steam turbine.

No gasoline turbine has ever been fitted to an automobile so far as we are aware, and the reason for this is that none has ever been made that would run reliably— ED.]

#### Number of Machines in Use.

Editor Horseless Age:

I have your issue of October 13, in which you reply to my inquiry for auto statistics. I think your estimate of the number of automobiles now in use in the United States (200,000) is much too small. Let us take the State of Iowa as a basis to guess at the number of cars in this country. We have a State law requiring every owner of a motor driven vehicle to take out a license and secure a number. We now have 13,200 such machines. Our population is about 2,300,-000, which is one machine for every 175 of our population. Counting 10 per cent. of our Iowa machines out of commission or destroyed, we have one machine for every 200 people in the State. I notice in a magazine article on automobiles that the State of New York has 80,000 machines in use, which must be about one for every 100 of your population. Taking Iowa as an average State in respect to ability to buy machines, and judging from the number in use in our State, I should think there must be 350,000 motor propelled vehicles (including electrics and steamers) now in use in

the United States. Some well posted men in the business place the number of new machines likely to be made next year at 200,000, with an estimated value of \$225,000,000. I am trying to get as nearly as possible the number and value of automobiles in use in this country.

#### ROBERT FULLERTON.

[In regard to your criticism of our estimate we have this to say: The Iowa law was passed in the spring of 1907 and has now been in force three seasons. The number of the latest registration is undoubtedly far greater than the number of cars actually in commission in that State at present, because (1) some of the cars registered in 1907 were old then and have since been retired; (2) many cars have changed hands during the period since the law was adopted. some even several times, and they generally get a new number every time; (3) not only automobiles but also motorcycles are included in the list. The same argument applies to the New York figures. In New York State 82,000 cars, approximately, have been registered to date, but the registrations began in 1901, and nine out of ten cars that were registered in the early years are now out of commission. These registration figures are of no value whatever for arriving at the number of cars, except where annual registration is required.

The figure of 200,000 for the number of cars now in use is undoubtedly quite close to the truth. It is based on the annual productions and an estimated ratio of annual retirements. The figure is moreover confirmed by a statement recently issued by the Association of Licensed Automobile Manufacturers, to the effect that 305,000 gasoline vehicles had been manufactured in this country to date. Electric and steam vehicles would probably raise this figure to about 325,000, and when it is considered that actual manufacturing began about 1898 and that the average life of the earlier vehicles did not exceed five years, 200,000 seems a quite reasonable estimate of the number of cars now in commission.—Ed.]

#### Graphite or Talc?

Editor Horseless Age:

In "Hints on the Care of Tires," in your issue of the 13th inst. you in part say: "It has been recently proposed to use flake graphite to lubricate the inner surface of the cover, but we have not yet heard regarding experiments with this material for this purpose."

For more than a year I have been using and recommending the use of flake graphite. I consider it so much superior to talc that the latter does not enter into competition with it. Early in the summer I wrote to the manufacturers of the tire which I use, calling their attention to the advantages of flake graphite as a lubricant for tubes.

Flake graphite will adhere to an inner tube for at least a year, whether the tube be carried loose in the car or in use in a casing. Talc will not adhere to a tube in any considerable quantity, and will chase around

in the casing until it all collects in one place.

A lubricant that will not adhere to the parts creating the friction must be considered as something of a joke. I am inclined to believe that there is as much difference between flake graphite and talc in preventing friction, between tube and casing as there is between talc and brook sand.

WILLIAM HINDS.

# Conditions Under Which Motor Trucks Can Be Successfully Operated.

Editor Horseless Age:

Can you refer me to any copies of your paper covering the preliminary investigations necessary to determine the conditions under which motor trucks can be successfully operated? If you have published nothing relative to this, would not an article by some experienced commercial vehicle man be very much in order? H. R. S.

[Although we do not remember having had an article under the exact heading mentioned by you, we have had many articles in which the conditions which are specially favorable to the automobile, as compared with horse vehicles, were pointed out. These conditions may briefly be summarized as follows: Relatively long hauls with few stops, good pavements, importance of quick delivery, and need for enough rolling stock to make the establishment of a well equipped private repair shop possible. There may be some other conditions, but the above are all that come to mind at the moment. —Ep.]

#### Fuel Economy Record.

Editor Horseless Age:

Will you kindly give me any data concerning the largest mileage from a single gallon of gasoline in any official contest, by a gasoline car? Also advise, if possible, whether a single cylinder Cadillac ever ran 42 miles or more on one gallon of gasoline in an authentic test? R. J.

[The present record in respect to vehicle mileage on a single gallon of gasoline is held by S. G. Averell, of New York, who in the One Gallon Efficiency Contest held by the Automobile Club of Buffalo, N. Y. on July 7, 1909, drove a Franklin air cooled car weighing, with passengers, 2,948 pounds, a distance of 46.1 miles on one gallon of gasoline. A single cylinder Cadillac car weighing with load 2,325 pounds was driven a distance of 42.6 miles on one gallon of gasoline in the One Gallon Economy Contest of the New York Automobile Trade Association on May 7, 1909.—ED.]

#### Horse Power Ratings.

Editor Horseless Age:

It would be of some value, I think, if you would publish for, say, fifteen or twenty of the leading makes of touring cars the actual rating of horse power, as rated by others than the makers. I am a subscriber to your paper,

but have seen nothing of the kind; or can I purchase such information anywhere?

L. R. WASHBURN.

[You can easily determine for yourself the standard rating of any car according to the A. L. A. M. rating formula. This formula was adopted by the mechanical branch of the Association of Licensed Automobile Manufacturers, and is believed to represent very closely the output of a good average engine at a piston speed of 1,000 feet per minute. By running at a considerably higher piston speed it is possible to get more power from an engine of given cylinder dimensions, but the high speed is a disadvantage in itself. The formula is as follows: Horse power per cylinder = bore in inches squared, divided by 21/2. Thus a cylinder of 5 inch bore will develop  $5 \times 5 + 2\frac{1}{2} = 10$  horse power. The length of stroke does not enter as long as the piston speed remains the same. The bore and number of cylinders are always given in our descriptions of cars, and you can therefore easily determine the A. L. A. M. rating of any car yourself.—ED.]

## Suggested Remedy for Difficult Steering.

Editor Horseless Age:

Noting the inquiry of P. M. Sharples in your issue of October 20, regarding the hard steering of his electric vehicle as compared with gasoline automobiles he has owned, allow me to suggest to him to bend his front axle so that the distance between the bottom of his two front wheels will be at least two or even three inches less than the distance between the top of the wheels, making sure that each wheel has the same inclination, and I am sure that his electric will steer perfectly.

I had the same trouble as he is now experiencing with a tiller steered gasoline car, and experts and many specialists tried to remedy it, but all to no avail. My car was always heading for the ditch. Not until after I had driven this car 20,000 miles, always with fear and trembling, and had been ditched many times because of this trouble, did I discover that by bending the front axle, as above stated, the trouble could be overcome and absolutely corrected.

E. K. LOVELAND, M. D.

#### Detroit Show Plans.

January 24 to 29, inclusive, are the days selected by the Detroit Auto Dealers' Association for their third annual automobile show, which will be held in the Wayne Hotel Gardens. This will be the eighth annual show held in Detroit, but only the third under the auspices of the dealers' organization. For the 1910 show there is 35,-000 square feet of available floor space. All decorations will be included in the price of space. The association has voted \$10,000 to be utilized in decorating the gardens, \$2,000 more than last year. John Gillespie has been chosen general manager of the event, and has opened office at the Hotel Tuller, Detroit.

## International Convention for the Regulation of Automobile Traffic.

An international convention, called by the French Government at the suggestion of the Homburg Conference of the International Recognized Automobile Clubs, met at the Palais of the Minister of Foreign Affairs in Paris on October 5, with the object of arriving at an agreement regarding the control of international automobile traffic. The following eighteen countries were represented: France, Germany, Austria, Hungary, Belgium, England, Italy, Russia, Holland, Spain, Portugal, Roumania, Switzerland, Servia, Montenegro, Monaco, Sweden, Bulgaria and the United States (by W. S. Hogan).

M. Gavarry, one of the French delegates, was elected president of the convention. After a brief discussion it was decided to hold the sessions in star chamber. Two committees were appointed, one for the purpose of studying all technical questions relating to automobiles and their drivers, of which the Belgiam delegate, Lagasse de Locht, was named chairman, and the other for the purpose of studying international traffic and customs proceedings, of which the German delegate, Baron Lancken, was named chairman.

During the second session, on October 6, there was a lively discussion regarding the requirements to be made of automobile drivers. The French Government made the following proposition: No one shall be allowed to drive an automobile without having first procured a permit, which will be issued to him by the competent authorities after he has demonstrated his competency. The permit is not to be issued to persons under eighteen years of age. In the determination of the applicant's competency the following rules must be observed: The applicant must be able to steer perfectly; he must have an intimate knowledge of the parts of the car and their functions. If the applicant is recognized competent, he will be given a driver's license from the competent authority. The German Government proposed the following amendment through Baron Lancken: "The driver must also possess the physical and intellectual qualities to enable him to drive calmly and collectedly in crowded streets and under the most difficult circumstances: he must have perfect eyesight and hearing, and must possess the moral qualities which insure sufficient guarantees to the public."

On October 7 the convention held its third meeting, at which it occupied itself with customs formalities. The following "The passage resolution was adopted: from one country into another can be permitted only to automobiles which carry in the rear, clearly discernible, a distinguishing mark of the country in which the car is registered. As concerns warning signals, the horn is the only device permitted, and every car must be provided with one. However, outside of built-up districts the use of other signaling devices will be permitted which are in accordance with the regulations and customs of the respective countries. Every car must be equipped with two lamps in front and one in the rear. The road ahead of the car must be illuminated for a sufficient distance, but the use of dazzling headlights in cities is prohibited. Motorcycles need only carry one lamp, which must be attached to the front."

The fourth session was occupied with a discussion on an agreement regarding auto traffic rules. It was resolved that auto drivers in meeting or overtaking other vehicles must always strictly comply with the customs of the district in which they are driving. Every one of the subscribing countries engages itself to see that for the designation of dangerous points along the roads only danger signals are erected which carry the marks agreed upon by the recognized automobile clubs. This system of road signs should be completed by a further sign indicating the proximity of a customs station, and a required stop. This sign might be in the form of a round white disc.

The governments of the different countries furthermore agree to observe the following regulations: I. It is in general unnecessary to indicate road obstructions in built-up districts by warning signs. 2. The signs should be erected at a distance of 250 yards ahead of the obstruction, etc., unless local conditions do not admit of this. If the distance of the sign from the obstruction is considerably more or less than 250 yards, special arrangements must be made. 3. The warning signs must be erected perpendicularly to the road.

#### **Business Troubles.**

The first meeting of the creditors of the American Automobile Engine Company, of Jamaica Plain, Mass., which was petitioned into involuntary bankruptcy in September last, was held on October 22. Schedules filed disclosed an indebtedness of \$142,726.08 and assets of \$42,241.15. The largest unsecured creditors are the International Trust Company, \$2,254.64; Whipple, Sears & Ogden, \$2,456.87, and F. J. Hall, \$6,799.11. Edward N. Golding was elected trustee, his bond being fixed at \$4,000. Mr. Golding reported to the court that it would be to the best interests of the creditors to sell the plant at Jamaica Plain, which is estimated to be worth about \$30,000.

The petition in bankruptcy against Walter G. Pierson, dealer in auto supplies, 43 Cortlandt street, New York, has been dissolved. Mr. Pierson denied that he was insolvent or had committed the acts of bankruptcy alleged in the petition.

The first motor car factory in Russia has just been started in connection with the Russo-Baltic Engineering Works, in Riga.

There are now 843 registered cars in Calcutta, 661 in Bombay, about 160 in Madras, with smaller numbers in other cities. French and English makes dominate the market in India.

#### The New York-Atlanta Good Roads Tour.

the thirty-eight competing cars being penalized. The running time for cars in Class

Monday morning, the 25th, promptly 45, 62 cars started from the Herald ing in this city, on the New York Id-Atlanta Journal Good Roads Tour, will end on November 3, at the office e Atlanta Journal, Atlanta, Ga. The Id entry list is given in the accomng table.

start was made under the superof the police department, and was le for the absence of confusion. The were drawn up in a double line around Herald Building in the order of their I numbers, the line extending along Sixth avenue side of the building d through Thirty-sixth street. The d cars were backed up to the curb in of the entrance to the building on v-fifth street. At the starting shot the I cars moved out and down Broadway order in which they were arranged, vere followed by the contestants, withany confusion whatever. The cars ipating were escorted down Broadway Battery by 75 cars, representing the York Automobile Trades Association, cars in the tour were taken across taten Island Ferry to St. George on ferryboats and then proceeded along Staten Island shore road to Perth by, escorted by members of the Rich-County A. C. The ferrying of the from Perth Amboy to Tottenville red several trips of the boat. Before g Tottenville a one hour's stop for was made at the Packer House. alf past I the run was continued e Quaker City. The drive through pleasant country, resplendent in its an dress, was enjoyed by all, and the day's run was completed without und incident.

leaders of the tour reached Philhia about 4 o'clock. The first car to was a Rainier, driven by Mrs. J. N. o, of New York. Mrs. Cuneo was panied by her husband, Mrs. Dis-F. Ed. Spooner and L. D. Disbrow. tourists were met at the city limits White steamer, driven by Stewart who piloted them to their stopping the Hotel Walton. Much interest aken in the cars along Philadelphia's row. The second arrival was the ners-Detroit Bluebird, driven by the all crack Ty Cobb, and occupied beby M. C. Reeves and E. Anderson. cars were parked during the night

e City Hall courtyard, where they under police guard. The Quaker Motor Club kept open house all event their rooms, on the second floor of fotel Walton, and the visitors were an impromptu reception, the club is welcoming the guests and wishing a safe journey for the rest of their

OFFICIAL CARS (Non-Contesting).

THE CARS ARRIVING IN HERALD SQUARE.

GETTING READY FOR THE START.

1 was 7h. 40m. The start from Philadelphia was made at 8 o'clock, and the first part of the day's run led over the most perfect of highways through the wealthy suburban towns of the Quaker City, which were oil-treated for the most part. But after Exeter, Pa., had been passed the good roads were left behind, and ordinary dirt country roads, quite hilly and with numerous water breaks were encountered. The only car to meet with serious trouble during the day was the Pope-Toledo entered by the Chamber of Commerce of Lynchburg, Va., driven by Carter Glass. Owing to some defect in the mechanism the driver was forced to return to Philadelphia and withdraw from the contest. The Knox car, driven by Joseph W. Jones, and which carried the referee of the contest, Winthrop E. Scarritt, broke a spring 20 miles northeast of York, Pa., and Mr. Scarritt was obliged to take passage on the Reo, driven by R. M. Owen, of New York, in which he completed the day's tour. After several hours effort Mr. Jones' party succeeded in finding a blacksmith who repaired the spring and the car was able to reach its destination.

The stop for lunch was made at York, Pa., which point was reached shortly after noon. During the afternoon considerable stretches of bad roads were encountered, and the contestants got their first taste of the difficulties in store for them. As on the first day, many of the contestants showed a disposition to drive at high speed, and Referee Scarritt was obliged to issue a warning to the effect that racing must not be indulged in. Late Tuesday evening Mr. Scarritt issued the following official bulletin:

"The second day's run of the New York Herald-Atlanta Journal good roads tour was completed about 4 o'clock this afternoon. Out of the thirty-eight entries checked out from Philadelphia thirty-seven reported at the night control. This is a splendid showing.

"By special arrangement provision was made for the contestants and their guests to drive over the historic battlefield of Gettysburg. This was a never to be forgotten pleasure, for which we are indebted to the courtesy, thoughtfulness and hospitality of the two great newspapers conducting the tour, and this crowned the end of a day of unmixed delight.

"One driver was warned for what was doubtless a thoughtless violation of the rules of the road. In this connection the referee calls attention to the rule in regard to too rapid driving, and warns contestants that reckless driving will not be tolerated. We now are approaching a part of the country where motor cars are much less frequently seen than in the

more populous centres. Greater care and caution, therefore, should be exercised, especially in passing through villages and towns and along narrow country roads, where one meets horses unaccustomed to the sight and sound of motor cars. In such circumstances contestants are asked not to drive at speed or to run with mufflers of their cars cut out. Let it be our fixed purpose to do unto the other users of the common highway as we would have them do unto us under reversed conditions."

The itinerary is as follows: First day, New York to Philadelphia, 99 miles; second day, Philadelphia to Gettysburg, 120 miles; third day, Gettysburg to Staunton, Va., 179.9 miles; fourth day, Staunton to Roanoke, Va., 92 miles; fifth day, Roanoke to Winston-Salem, N. C., 125.8 miles; sixth day, Winston-Salem to Charlotte, N. C., 137.6 miles; seventh day, Sunday, spent in Charlotte, N. C.; eighth day, Charlotte, N. C., to Greenville, S. C., 10 Commerce, Ga., 109.8 miles; tenth day, Commerce to Atlanta, Ga., 81.5 miles.

The classification of cars is as follows:

	**	-	•	9	8	ы	**	ш	3	-	ш	ы	œ	•		-	•		-	и	а	Е	•		(2) 68-2	•	CALLES.	17 C ×

77	6			٠		٠	٠	ı					2								۰		۰		80	o	and	under	

The rules governing the contest may be briefly summarized as follows: Stock cars only may compete. Touring cars must carry four or more persons, or the equivalent in dead weight ballast, at the rate of 125 pounds per person; runabouts, two or more persons, or the equivalent; miniature tonneau cars, four or more persons, or the equivalent. Each competing car must be examined by the technical committee. No car shall pass the pacemaker. Contestant may carry as many tires and tire accessories as desired or purchase same en route, and no

WAITING AT THE FERRY TO STATEN ISLAND.

penalty shall be imposed for tire repairs, but time so lost must be made up. Frames and engine castings are to be sealed before the start, and any replacement of these parts shall result in disqualification. Customary rules regarding checking in and out at controls are to be observed. Time penalization is to be as follows: After an allowance of two minutes, each late arrival shall be penalized one point for each minute or part thereof. Trophies aggregating in value at least \$1,700 are to be awarded to the winners in the different classes, and a suitable trophy is to be awarded to the private owner having the least points to his debit, provided he has not won a class trophy.

Winthrop E. Scarritt, of New York, is referee of the contest; Frank X. Zirbies, of Wisconsin, pacemaker; E. L. Ferguson, of Buffalo, starter; Mortimer Reeves, of New York, and Inman Gray, of Atlanta, are checkers.

Vanderbilt Cup News.

Practice on the course has been going on all through the past week, and speeds better than a mile a minute were made. The technical committee opened its head-quarters at Monk's store, near the railroad station in Garden City, for the purpose of making an examination of such cars as were ready, and the drivers and managers of racing cars were requested to immediately notify A. L. McMurtry, the chairman of the technical committee, where they could be found.

The drawing for positions in the race will be held at the Garden City Hotel at 8:30 o'clock on Thursday evening. As in previous years, there will be two drawings—the first to indicate the order of drawing, and the second drawing for the order of start in each class. It is important that all the drivers and managers of the cars entered in the races attend this meeting, as the referee and Starter Wagner will issue their final instructions to the racing crews at this time.

In this connection it might be stated that little time will be lost in starting the cars, as, owing to the short circuit this year (1264 miles), it will be necessary to send

CARS LINED UP AT PERTH AMBOY FERRY.

the cars away at 10 or 15 second intervals instead of a minute apart as in former years. The Long Island Railroad announce that they will run special trains from East Thirty-fourth street and Flatbush avenue at frequent intervals between 4:30 and 8 a. m. on October 30, the day of the race. Some of these specials will run to Westbury and Hicksville, others will run direct to the grand stand as follows: East Thirty-fourth street at 6:50 a, m., 7:10 a. m. (all parlor cars) and 7:30 a. m. Flatbush avenue at 7:30 a. m., stopping at Nostrand avenue and East New York. A special excursion fare of \$1.25 will be charged on these trains. Among the new entries are a Columbia and a big Atlas, two cycle, four cylinder car.

The Bosch Magneto Company offer the following prizes to the winners if equipped with their magnetos: To the winner of the Vanderbilt Cup, \$250; to the winner of the second prize, \$150; to the winner of the third prize, \$100. The company will have two experts on the course during the race, with a complete line of extra parts and ready to assist on all cars equipped with their magnetos.

Following their custom, the officials of the Maxwell-Briscoe Motor Company have leased a tract of land opposite the grand stand, for the free and exclusive use of owners of Maxwell cars who desire to view the race. The ground furnishes ample room for over 500 cars.

The following is the complete list of entries for the three events:

The Carl H. Page Company, New York agents for the Chalmers-Detroit car, have

THE MITCHELL PACEMAKER.

R. M. OWEN, DRIVING THE NEW MODEL 1910 FOUR CYLINDER REO ROADSTER.

secured parking space at the side of the track opposite the grand stand and issued an invitation to all owners of Chalmers cars to make use of it.

The best time in practice so far was made by Bert Dingley in one of the Chalmers Bluebirds, on Tuesday, viz.: 11 minutes flat. A number of accidents have also occurred due to skidding, but none very serious. The Moon car, driven by Phillip Wells, crashed through a wire fence and turned turtle, and may not be able to compete, as all four wheels were smashed and the frame bent. The mechanic was injured, but the driver jumped and escaped harm. It is as yet uncertain whether repairs can be made in time for starting the car in the race.

While the entry list has been nominally closed the management still expect several additional entries, but will not announce the cars until the checks for the entry fees have been received.

#### The Atlas Entry for the Vanderbilt Cup Race.

The car which the Atlas Motor Car Company have entered for the Vanderbilt Cup Race is the first two cycle car which has ever taken part in a long distance road race. The car is claimed to be capable of a speed of from 75 to 80 m. p. h., which is said to be made possible by improvements in the two cycle motor, enabling it to run at an extraordinarily high piston speed. The motor is a four cylinder one of 5 inch bore and stroke each, the bore and stroke being 1/2 inch more than in previous Atlas models. This motor is said to develop 60 horse power, at 1,200 r. p. m. The car belongs to Class 2, having a piston displacement of only 393 cubic inches, as against the limit of 600 cubic inches for cars in Class I. The car is a new model that will be sold by the Atlas Motor Car Company next season, equipped with either a seven passenger touring car body or a baby tonneau body. The body is of aluminum and is mounted on a drop frame. The wheels are 36 inches in diameter.

#### Test of the Atlanta Speedway.

A trial of the two mile speedway at Atlanta, Ga., was made on Saturday of last week, in the presence of several thousand spectators, who paid 50 cents each to get into the enclosure. Some of the most noted drivers in the country took part in the trial, for which an official sanction was issued by the A. A. A. The cars were started by Fred J. Wagner. Those who went specially to Atlanta to participate in the test were Barney Oldfield, who drove a Benz racer, George H. Robertson, driving a Simplex, Basle in a Renault and Kirscher in a Darracq. Besides these, Asa G. Candler, Jr.'s Pope-Toledo car was tried out on the course by Cliquot. The races, which started at 2 o'clock, proved the track to be one of the fastest that has ever been built, although it was still slippery in spots from freshly applied oil. The best time was made by Barney Oldfield, who drove five miles in 3.52 3-5. The results of the day are summarized as follows:

Three Cornered Race, 10 Miles: Robertson, Simplex, won, 8:21.2; Cliquot, Pope-Toledo, second, 8:34.2; Basic, small Renault, third, 10:13.2. Amateur Driving: Ed Durant, of Atlanta, Renault, 5 miles in 5:08; champion amateur driver

#### Split in Denver Trade.

Unwillingness to support the local show planned by the Denver Motor Club for March next has led to the organization of the Denver Automobile Dealers' Association with the following officers: F. L. MacFarland, president; E. Linn Mathewson, vice president; L. R. Stone, secretary, and E. E. Zook, treasurer. Tom Botterill, J. H. McDuffee and W. W. Barnett were chosen as an executive committee to act with other officials, who serve for one year.

The new organization at once passed a resolution not to take part in any show this year. It seems that the dealers took offense at not being consulted by the Denver Motor Club regarding the arrangements for its show, and that they are opposed particularly to the date set for it, in March, when, they say, people begin to think about 1911 models, and know all about those of 1910, which would be the only ones available for exhibition.

#### Co-operative Garage Trust Scheme.

In our last issue we announced the incorporation of the Buick Auto Supply & Garage Company of Saginaw, Mich., under the laws of the State of Maine. The company derives its name from Thomas D. Buick, who formerly conducted an automobile supply business in Flint, Mich. According to prospectuses sent out by the new company, it plans the establishment of a network of garages and supply stores in all the printipal cities of the country, on the co-operative plan; that is to say, it expects to raise the capital for the local companies among the automobile owners who will be the customers of these companies. It stated that subsidiary organizations have been practically completed under the direction of the parent company in Michigan, Indiana, Ohio and Illinois.

The Utah Retail Automobile Dealers' Association was organized at a meeting held at the Commercial Club in Salt Lake City, on October 12. One of the chief objects of the organization is to conduct an automobile show in the Auditorium in February next. Most of the local dealers were represented at the meeting, and steps for permanent organization were taken. The following officers were elected: Fred Raymond, president; Frank Botterril, vice president, and Roger W. Powers, secretary and treasurer.

# Commercial Applications

## An Auto Transportation Service in Porto Rico.

C. H. Martin, of New York, has just returned from San Juan, Porto Rico, where he organized and established the service of the Porto Rico Auto Transportation Company. The latter concern does a passenger transportation business between San Juan and the residential suburb, Santurce, with four 30-passenger motor buses. The service is conducted in direct competition with a trolley service. One of the factors which gives the motor transportation company a considerable advantage is that the trolley line has only a single track, and its cars are delayed a great deal on switches, which enables the motor transportation company to save its patrons from 15 to 20 minutes of time on the five-mile trip. The fare charged is five cents. The service was started on July I last.

The cars were built after Mr. Martin's designs at the shops of the American Motor Truck Company in Lockport, N. Y. The buses are equipped with four-cylinder, 51/4 by 6 inch Herschell-Spellman motors, and a massive planetary change speed gear. The front wheels are equipped with 5-inch single solid tires, and the rear wheels with 4-inch dual tires. The tires, by the way, have been the only parts to give trouble so far. They began to creep on the rims, and this has been the only cause for withdrawing cars from service for short periods. Aside from these short delays, the cars have been kept in service for 24 hours a day. The seating capacity of each bus is 30 passengers, but as many as 47 have been carried on one vehicle during rush hours. The company runs its vehicles over a single line, which parallels the trolley line, and cars are run at 15 minute intervals. Native drivers are employed, and in addition to the driver a conductor accompanies each

One of the special requirements in a vehicle for service in that locality is an extremely large radiator. The district is quite hilly, numerous stops are required, the buses naturally must be run at a relatively slow speed, and the climate is hot, so that the necessity of providing large cooling capacity is easily explained. The radiators of these buses are supported on trunnions by means of spring supports and are held in their vertical position by hose connections. The axles of the vehicles are of Timken construction.

# To Furnish Autos Under a Service Contract.

The Auto Contract Company has been organized at New York for doing a general auto renting business under contract for terms from one month up, and has established headquarters at 26 East Twenty-

eighth street. The company will furnish both gasoline and electric vehicles for either pleasure driving or commercial purposes. The charge for electrics for pleasure driving will be from \$300 per month up, that for gasoline vehicles for the same purpose from \$450 per month up, and that for commercial vehicles from \$350 per month up. The company will guarantee to keep the cars in perfect condition and will have drivers on call at any time in the case of pleasure cars and for ten hours a day in the case of commercial vehicles.

#### Commercial Applications.

The C. K. Taxicab Company is being organized in Cincinnati, Ohio., with a capital stock of \$200,000, and it is planned to begin operation with 20 cabs, and to increase the equipment to 50 by the first of the year. The rates will be 30 cents for the first half mile and 10 cents for each additional quarter mile.

The city officials of Pittsburg, Pa., are planning to "motorize" the equipment of the downtown fire engine houses. Chief Engineer Miles F. Humphreys, of the Pittsburg department, is said to be very favorably inclined toward motor propulsion. The first changes are to be made at engine houses No. 19 in Water street, and No. 3 on Seventh avenue.

The City Council of Los Angeles, Cal., may decide upon the use of one particular make of machine in the city departments in the future. A committee have been appointed to investigate the merits of all machines offered to the city, and to make a report to the council on the machine they consider the best for all the various municipal uses. One of the first purchases will be an automobile for the health department.

Fire Chief W. B. Cummings, of Atlanta, Ga., is opposed to any further purchase of horse drawn vehicles for his department. He has witnessed the performance of motor propelled fire engines, hose wagons and trucks, and considers them a great deal cheaper and more effective than the old style apparatus. Chief Cummings will endeavor to have all of the suburban stations equipped with the new kind of apparatus.

The Baker Electric Vehicle Company has recently furnished an electric delivery wagon for use in handling baggage for the executive office of the White House. The car was made on a special order for the Government. It has a 42 cell, 9 P. V. Exide battery, a wheel base of 85 inches and 34x3 inch solid rubber tires. The body was specially designed and built by the Brown Auto & Carriage Company. The car is capable of carrying a load of 1,000 pounds.

#### Business Opportunities.

The city of Lockport, N. Y., has decided to purchase a motor propelled hook and ladder truck. All communications regarding this matter should be addressed to W. M. Trevor, 165 Pine street.

#### New Record in Portola Race.

Jack Fleming, driver of the Pope-Hartford car, won the chief event in the Portola race at Oakland, Cal., on October 23. The distance was approximately 258 miles, and was covered by Fleming in 3h. 58m. 15s., at an actual average speed of 64.51 miles per hour. This is a new record, breaking the world's record established at Santa Monica, Cal., of 64.44 m. p. h., and that of the Vanderbilt Cup race of 64.42 m. p. h.

The race was held over a 21 mile circuit which was covered 12 times. Two cars were within two laps of the winner at the finish, namely, the Apperson, No. 13, driven by Harris Hanshue, and the Lozier, No. 12, driven by Harry Michner. The Apperson made fine spurts toward the last in trying to overtake the Pope-Hartford, but did not succeed in doing so. It led the Lozier, No. 12, by almost a lap at the finish.

The Apperson car, driven by Hanshue, won the second race, covering the 210 miles in 3h. 12m. 33s., and the Lozier secured second place in this race. The first race, consisting of seven laps, was won by the Pope-Hartford. Fleming also made by far the best time in the second race, but as he was not entered in this event it did not count. It was in the final event, the free for all over a course of 258 miles, in which the Pope-Hartford scored its triumph.

The race was marred by a number of accidents, at least one of which proved fatal. The Knox, No. 11, driven by Frank Free, left the course near San Leandro, and killed a spectator. Free and his mechanic, Joe Robinson, were thrown out and badly bruised. When the Sunset car rounded a turn, a metal tire retaining ring flew off into the crowd, fracturing the skull of a man named McKittrick. The Chalmers-Detroit, No. 7, struck a fence near San Leandro and turned turtle, but no one was injured in the accident.

#### Scarcity of Labor in Indianapolis.

Automobile factories in Indiana are confronted with an inability to get sufficient workmen for their plants. All Indiana industries are now working full time, while the automobile factories are practically all working overtime on 1910 cars. Although wages have been advanced, men cannot be found to fill waiting positions. The State statistician, J. L. Peetz, is conducting a free State employment bureau in Indianapolis and has received a request for 500 men from the Maxwell-Briscoe Motor Company, which has a plant at Newcastle. Probably 100 men experienced in automobile work could get positions in Indiana factories, it is said.

F. H. Sims has been named assistant secretary of the Columbus (Ohio) Automobile Club to succeed Mr. McIntire, who was compelled to relinquish the office because of a press of other business.

# A Fire Insurance Policy Does Not Cover Damage by a Collision Followed by a Fire.

A judicial decision in an insurance case which ought to be of considerable interest to all automobile owners has just been given in Fall River, Mass. The suit was brought by L. Clifford Bodge, of that city, against the Automobile Mutual Insurance Company of America. In June last Mr. Bodge's automobile, at a curve in the road at the approach to the Cole's River bridge in Swansea, Mass., left the road and collided with a tree. The car turned a complete somersault, caught fire and was completely destroyed so far as any further use was concerned. At the time of the accident the car was in charge of an employee of the Flint Motor Company, of Providence, at whose shop it had been overhauled and repaired. The driver and a companion were both thrown out and injured, but not seriously. Mr. Bodge had bought the car, a 30 horse power touring car of well known American make, from a former owner, and took over from him a \$3,800 fire insurance policy on the car in the Automobile Mutual Insurance Company of America, located in Providence, the policy having been taken out when the car was new. The owner of the car claimed practically total loss, and made claim for \$2,750. The insurance company, on the other hand, claimed that the greater damage was done by the collision, and offered \$1,000 in settlement, which was refused. A clause in the policy provided that in case of difference over a claim appraisers should be appointed, and this was done. The appraisers have just made a report recommending an award of \$810. Mr. Bodge, the complainant, has not yet decided whether to accept the award, as he also has an action pending against the Flint Motor Company in an endeavor to make them responsible for his loss, as he claims that the car was still in charge of the company when the accident occurred.

#### Revising Denver's Auto Regulations.

A committee from the Denver Motor Club, headed by President Ralph Smith, held several conferences with the fire and police boards for the purpose of drawing up a new ordinance code which will make the automobile laws and regulations uniform. The committee claims that the present code is inadequate. The attention of the boards was called to the trafficking of numbers, particularly by garage owners, who do not report the transaction, thus baffling the police in cases of accident. The committee also recommended that professional drivers of automobiles be examined by a board, to be created for that purpose, and that without a certificate from such

board a license should not be granted. A charge sufficient to cover the expenses of these examinations will be made. Taxicabs and their fares will be regulated, and a license fee will be imposed on all garages. The existing rules covering the display of numbers on the front and rear of machines are to be enforced with increased rigor.

#### Failure to Have Lamps Lighted as Required by Ordinance is Negligence.

Under an ordinance making it unlawful to operate an automobile in the city between one-half hour after sunset and one-half hour before sunrise, without the proper lights, describing them, it was held that the failure to have lights, where a pedestrian was struck, was negligence. The court instructed that this established negligence, and it was not necessary for the plaintiff to make any further showing of negligence in order to recover. It was held that the omission to perform the duty required by statute "should contribute directly to the injury," otherwise no action for damages could be maintained. It was further held that the subsequent instruction set this forth, and, as a whole, the instructions were right. Judgment for plaintiff. Fenn vs. Clark, 103 Pac. 944 (California.)

#### Ohio Law Upheld.

The Ohio Supreme Court, in a decision handed down last week, upheld the constitutionality of the Ohio automobile law The constitutionality of the statute was attacked by T. M. Drolesbaugh, of Crawford county, when he was arrested for driving his car without registering it. He pleaded the arbitary discrimination of the law against auto vehicles in favor of horse drawn vehicles, and asked that the law be declared unconstitutional. He said it violated Art. I of Sec. 2 of the Ohio constitution. The decisions of the lower court, which were against the plaintiff, were upheld.

# Enacting State Law as City Ordinances in Wisconsin.

The recent decision of a Wisconsin court that the State law regulating automobiles supersedes any city ordinance to the same effect has led the common councils in a number of cities to adopt the State law as a city ordinance. This procedure permits the city attorney to conduct prosecutions, the resulting fines, if any, going into the city treasury. While the district attorney was the proper prosecutor, fines went into the State Treasury, in cases where the State law and city ordinance were at variance. The State law permits of a speed of 12 miles an hour in cities, and 25 miles in the country.

#### Legal Notes.

The Board of Aldermen, of the City of New York, on October 19, passed an ordinance appointing a number of taxicab inspectors, but did not provide any funds for meeting the cost of inspecting the cabs.

The city council of Chicago has adopted and Mayor Busse has signed an ordinance which prohibits the establishment of a public garage within 200 feet of a school or hospital. The ordinance was adopted with the immediate object of preventing the erection of a public garage near the Graeme-Stewart School.

The Ohio State Automobile Department has issued orders to police departments to see that all number plates are clean and legible at all times, or to arrest the driver. It is the intention also to put a stop to the practice of some owners of taking a hammer and battering the tags in order to make them illegible.

Dr. J. J. Kindred, superintendent of the Astoria Sanitarium, was rebuked by Magistrate Herrman in the Morrisania (N. Y.) Court last week for having driven at a speed of 25 miles an hour on Pelham Parkway. The doctor explained that it was absolutely necessary to get a patient to the hospital as soon as possible, but his chaufeur was held for trial.

The Massachusetts Highway Commission has withheld its approval of the special automobile speed ordinance passed by the selectmen of the town of Yarmouth. The commission is of the opinion that the State law recently enacted should be given a fair and reasonable trial, and no special regulations should be made by municipal authorities and approval by the board except under unusual circumstances.

The Florida Legislature has just passed an automobile law which does not establish a definite speed limit, but requires automobiles to be driven at a speed that is "reasonable and proper, with due regard to the use and traffic of the highways." All cars must be registered, and a fee of \$2 is exacted for the registration. Chauffeurs must also register. Non-residents registered in other States are exempt for thirty days.

Columbus, Ohio, Show Dates Set. The Columbus (Ohio) A. C. will hold a motor show in the Columbus Auditorium for eight days, excluding Sundays, beginning December 25. At a recent meeting of the club the date was decided on after consultation with Sidney Black, of Cincinnati. The hall has a larger floor space than any similar structure in Ohio. A committee consisting of Perin B. Monypeny, Herman Hoster, N. O. Aeby, Fred H. Caley and D. Kelly has been named to arrange the details. A general admission of 50 cents will be charged. Excursions will be run on all railroads and interurban lines entering Columbus.

The Toledo Motor Car Company, which is controlled by the Overland Automobile Company, has petitioned the municipal authorities of Toledo, Ohio, to vacate certain streets and alleys. The company owns all the surrounding property and plans to erect additional buildings.

The new State highway around Jacob's Ladder, in the town of Becket, Mass., is now open for traffic.

The Bartholomew Company, of Peoria, Ill., have begun the manufacture of cars in their new factory on Prospect Heights,

The Maumee Rubber Company, of Toledo, Ohio, have secured the exclusive agency for the Hoffecker speedometer in northwestern Ohio.

The Croxton-Keeton Motor Company, Massillon, Ohio, opened a branch store at No. 16 Columbus avenue, Motor Mart, Boston, Mass. This store will be in charge of L. F. Witherell.

H. S. Firestone, the tire manufacturer, on the basis of specifications of purchasing departments of automobile makers, estimates that 135,000 new cars will be produced next year in this country.

Chauffeurs in Reading, Pa., are planning to organize a union and establish a minimum wage. The chauffeurs of the Reading Taxicab Company are also planning to organize a club for purely social purposes.

The Los Angeles (Cal.) Automobile Dealers' Association, at a meeting held on October 12, decided by a very close vote against holding another show late this year. The meeting was held at the Franklin agency.

At the last meeting of the Automobile Dealers' Association of Pittsburg the following officers were elected: W. N. Murray, president; Frank Haupt, vice president; J. E. McKeogh, secretary, and G. P. Moore, treasurer

The run for the Brazier Cup, held by the A. C. of Philadelphia, on October 16, was won by G. B. Fletcher, who drove a Packard car., Mr. Fletcher's number was 13, and he also had 13 penalty points assessed against him.

The New Idea Spreader Company, of Coldwater, Ohio, announces that it will soon place on the market a business man's automobile, which will be simple in construction. The company has been making farming machinery.

A decree has been granted to dissolve the Carrico Motor Company, of Cincinnati, Ohio, upon an application of O. E. Walker and others, and R. A. Le Blond has been instructed to take charge of the assets and wind up the concern.

The chauffeurs of Atlanta, Ga., met in the Austell Building on October 17, and organized an association. It is planned to secure suitable quarters and to arrange for a course of instruction in automobile mechanics. The following officers have been elected: C. W. McDade, president; C. H. Walsh, vice president; E. L. McIntyre, secretary; Thomas Lane, treasurer; James R. Moore, conductor; Robert Schnore, warden; W. B. Maddox, inner guard; C. F.

Cavell, outer guard; H. L. Bell, chaplain; E. Walter Tripp, organizer.

The report of Ohio State Automobile Registrar Fred H. Caley for the month ending October 15 shows the revenue of the department for the month to have been \$5,039. There were registered with the department 685 new owners, 15 manufacturers and dealers and 125 chauffeurs. Renewals of owners numbered 256.

The new Atlanta speedway which has been constructed at an approximate cost of \$300,000 by the Atlanta Automobile Association, has been turned over by the contractors to the owners. A number of trials are this week being held on the two mile track to discover any possible imperfections before the first regular meet is held.

A chain of agencies is to be established in Wisconsin by the Wadhams Oil and Grease Company, of Milwaukee. The first tanks will be established at Two Rivers, Wis. The concern does a large business with automobile manufacturers and garages and will pay special attention to transient trade in the smaller cities of the State.

A factory to be devoted almost exclusively to the manufacture of automobile bodies is being erected in Milwaukee, Wis., by Fred C. Schueler & Brother, wagon and carriage makers, who some time ago started the production of bodies on a small scale. The factory will be 40x120 feet in dimensions, three stories high, and cost \$35,000.

The Pierce-Arrow Motor Car Company, of Buffalo, N. Y., will again this winter conduct courses of instruction for owners of Pierce cars, drivers, and dealers and repair men. Each of the courses will be of fourteen days' duration. It is likely that two class terms will be set aside for colored drivers, as has been the custom in the past.

The city of Milwaukee will next year treat all of the main streets, parkways and boulevards with asphaltoilene, as it has been found from exhaustive tests that a square yard of street can be kept dustless all season at an expense of about 1 3-10 cents. A mixing plant and tanks have been located in Riverside Park.

Owing to the fact that the confetti car got lost and one of the contestants followed it, the referee of the recent sociability run from Indianapolis to French Lick has decided to award two prizes. One of these will go to Charles G. Gardner, who followed the correct route, and finished within one minute and fourteen seconds of the secret schedule, and the other to Will A. Atkins, who probably would have made about the same time had he not followed the confetti car.

On November 1 the advertising office of the White Company will be moved fro. a its present location at 1402 Broadway, New York City, to the White factory, 800-898 East Seventy-ninth street, Cleveland. R. H. Johnson, who for the last six years has been in charge of the advertising and publicity affairs of the company, will continue his duties as advertising manager at the new address, Mr. Johnston will change

his place of residence from the Engineers' Club, New York, to the Hollenden Hotel, Cleveland.

A new type of automobile tire, claimed to be absolutely puncture proof, will soon make its appearance in Milwaukee, Wis. William A. Schoen, a manufacturer and president of the Milwaukee fire and police commission, announces that he has acquired an interest in the invention, and that a company will be organized to manufacture the tire in Milwaukee.

The Bosch Magneto Company have established a Western and Pacific Coast branch at 537 Van Ness avenue, San Francisco, Cal. The new branch will be equipped similarly to the Chicago branch, and will carry a complete stock of Bosch magnetos, parts and fittings. B. F. Brinkman will be manager of the branch, which was formally opened on October 20.

#### Crown Point-Lowell Grand Stand Taken Down.

The officials of the Chicago A. C. have given orders for the demolishing of the grand stand which was erected at Crown Point, Ind., last year for the Crown Point-Lowell races, and which has a capacity of 10,000. The wrecking work has already begun. It will be remembered that the race resulted in a deficit of \$30,000, and it was concluded that the club had abandoned the idea of holding another race on the course.

The officials of the club state, however, that the fact that the grand stand is at present being taken down does not indicate that the club will not repeat the race which it held on the Indiana circuit last summer. The grand stand, it is stated, was erected on a salvage basis by a Crown Point contractor, who has been endeavoring to get the club to make an agreement to use it next year, but the latter would not assume any obligation in the matter.

# Motor Speedway Planned for Detroit.

Plans are maturing for the construction of a model speedway in the vicinity of Detroit, Mich. The promoters are said to include "Bob" Oakman, and a leading automobile manufacturer in a city a short distance from Detroit. Options have been secured on two sites by the parties interested. Both of these tracts are located near the Grosse Point trotting track on East Jefferson avenue. One of the tracts has an area of over 400 acres and the other of 360 acres. The turns are to have a radius of 1,000 feet, and the straight-aways are to be similar to those of the Indianapolis Speedway. The course is to be laid out to the same general shape as the Indianapolis Speedway, making the distance around the outside between 21/2 and 3 miles, and the total distance around the outside and through the infield 5 miles. The outside circuit is to be paved with brick or creosote block.

# Garage Notes

TAYLORVILLE, ILL.—The Christian County Auto Sales and Garage Company are looking for a site on which to erect a one-story 40x125 feet building.

MILWAUKEE, WIS.—Koss Bros., Belleview place and Downer avenue, are building a \$10,000 addition to their garage. The addition has dimensions of 30x80 feet, one story high.

ROCKVILLE, IND.—S. F. Puett and Frank

ROCKVILLE, IND.—S. F. Puett and Frank M, Adams have purchased the F. R. Calvert garage west of the Parke Hotel. Mr. Calvert will go to Lake Charles, La., to conduct a garage business there.

BEAUMONT, TEX.—Louis Durango, manager of the Beaumont Motor Car Company, has purchased the interest of the Houston Motor Car Company in that concern, and is now looking for a suitable carrage.

a suitable garage.

EL RENO, OKLA.—John Ozum is to erect a 36x100 feet garage on Hayes street between Evans and Grand avenues. It will contain a first-class repair shop, over which Jim Gephart, of Oklahoma City, will have charge.

City, will have charge.

TRAVERSE CITY, MICH.—A. J. Peteryl, proprietor of the Traverse City Wagon Works, will remodel his two-story brick building on Union street as a garage. The lower portion of the building will be cement floored.

SAN FRANCISCO, CAL.—Hazlitt L. Pelton, one of the best known automobile dealers on the Coast, has assumed the position of sales manager for the Wagner-Reniff Motor Car Company, agents for the Auburn car, and will also handle the Columbia in northern California.

FALL RIVER, MASS.—Robert W. Powers, who has been the local representative for Peck & White, carriage and automobile dealers, for the past seventeen years, has secured control of the business. Mr. Powers will handle Peerless, Pope-Hartford, Buick, Oldsmobile and Oakland cars.

HOUGHTON, MICH.—The Northern Garage and Supply Company will open a garage on the water front, east of the Amphidrome. The building is a two-story 50x100 feet structure. A complete retreading and vulcanizing plant is to be installed. Ernest Hanson will have charge of the repair department.

RHINELANDER, WIS.—J. H. Morgan has organized the Morgan Garage Co., and has opened for business at 22 South Stevens street, Rhinelander. The electrical business conducted by W. H. Gilligan has been consolidated with the garage, and Mr. Gilligan will join the company as manager of the electrical department.

CHICAGO, ILL.—The local branch of the Overland Automobile Company will take over the entire equipment of the Auto Rebuilding and Machine Company, of 1720 Michigan avenue, and will move immediately to that address from its present location at 1413 Michigan avenue. John Phillapot, who was formerly connected with the Olds Motor Works, will be superintendent of the rebuilding and machine work department.

KANSAS CITY, MO.—An ordinance giving Theodore Winningham permission to erect a garage on South Main street, between 36th and 37th streets, was taken up for discussion by the fire committee, who recommended that the permit be revoked, as Mr. Winningham asked to build the garage flush with the street property line, while a special ordinance requires that all garages and livery stables be set back 16 2-3 feet from the sidewalk.

MILWAUKEE, WIS.—The main garage of the Jonas Automobile Co., one of the largest agencies in the Northwest, has been transferred from 726-728 National avenue to 417-421 Wells street. The Jones company, handling the Cadillac and Peerless, found the National avenue location to be too far removed from the business district. The Wells street garage was built last winter for the \* of the W. L. Hibbard Motor Car Co., which gone out of business.

# New Incorporations

The South Texas Automobile Company, Falls City, Tex.—Capital stock increased from \$3,000 to \$5,000.

The Oswald Motor Company, Goshen, Ind.— Increase of capital stock from \$30,000 to \$40,000. J. E. Newell, president.

Colonial Motor Car Company, Springfield, O.— Capital stock, \$3,000. Incorporators, W. L. Crist, J. A. White, Wm. J. McDaniel.

The Dover Inn Auto Club Company, Dover, N. J.—Capital stock, \$6,000. Incorporators, Fred Lyons, I. Strauss and Sarah Albers.

The Herold Reo Company, Cincinnati, O.— Capital stock, \$5,000. Incorporators R. Herold, T. M. Herold, John A. Smith and M. B. Smith.

The Payne Motor Company, Cincinnati, O.—Capital stock, \$10,000. Incorporators, R. S. Payne, E. E. Berry, A. M. Cohen and Alfred Mack.

Harriman Garage Company, Nashville, Tenn.—Capital stock, \$5,000. Incorporators, M. V. Thornton, M. Stover, F. M. Kennedy, L. O. Scott and J. W. Scott.

The Bowling Green Automobile Company, Bowling Green, Ky.—Capital stock, \$5,000. Incorporators, C. H. Smith, W. F. Toops, L. H. Conkin and Harry Ennis.

The Utah Motor Company, Salt Lake City, Utah.—Capital stock, \$1,000. Incorporators, D. C. Jackling, Chas. W. Whitely, Jos. W. Bidwell, John M. Hayes and W. P. Joy.

Elmore Mfg. Company, Clyde, O.—Capital stock, \$600,000. To manufacture automobiles. Incoporators, James H. Becker, B. A. Becker, M. A. Becker and B. H. Becker.

The Indiana Motor and Mfg. Company, Indianapolis, Ind.—Capital stock, \$100,000. Incorporators, Chas. B. Riley, John E. Matson, John C. Billheimer, C. C. Jones and others.

Knoxville Everglade Company of Knox County, Nashville, Tenn.—Capital stock, \$10,000. Incorporaters, W. D. Williams, J. W. Provost, J. M. Cassil, J. R. Williams and John W. Green.

The Anhut Motor Company, Detroit, Mich.— Capital stock, \$150,000. Incorporators, J. N. Anhut, Mayor Breitmeyer, H. H. Thorpe, John B. Chaddock, Thos. Ahern and John Gillespie.

Chaddock, Thos. Ahern and Join.

The Veerac Motor Company, Minneapolis, Minn.—Capital stock, \$400,000. Incorporators, Virgil Dillin, W. E. Decker, W. A. Zalondeck, F. K. Sullivan, W. A. Parjer, G. W. Buffington and F. H. Merrill.

American Automobile Aerial Road Company, Wellsburg, W. Va.—Capital stock, \$250,000. Incorporators, Assa G. Neville, F. A. Chapman, Assa A. Neville, of Wellsburg; Chas. L. Foreman, Steubensville, O., and John Ehmann, Cincinnati, O.

Boston, Mass.—V. J. Jacobs, Pierce.
Dallas, Tex.—Arthur Ove, Kissel Kar.
Atlanta, Ga.—Tyrus Cobb, Hupmobile.
Portland, Ore.—Fred Bennett, Renault.
Trenton, N. J.—Harry J. Stout, Pullman.
Trenton, N. J.—R. C. Manning, Autocar.
Atlanta, Ga.—Dr. H. K. Schwartz, White.
Luverne, Minn.—H. Bierkamp & Son, Buick.
Los Angeles, Cal.—Coney C. Slaughter, Stearns.
Houston, Tex.—Olds-Oakland Company, Rapid.
Cincinnati, O.—Imperial Motor Car Company,
Gaeth.

Osakis, Minn.—Guy Livingston, Jackson and Fuller.

St. Joseph, Mo.—Emmett Beckley, White steamer.

Washington, D. C.—L. P. Dorsett Company, Mitchell.

Dayton, O.—The Peckham Motor Car Company, Franklin.

Denver, Col.—Sanford Automobile Co., Crox-ton-Keeton.

El Paso, Tex.—Mosehart & Keller Automobile Co., Haynes.

Newton, Mass.—Evans & Warren, 24 Brooks street, Austin.

Houston, Tex.—Auto & Motor Boat Co., Franklin and Metz.

Oneonta, N. Y.—The Oneonta Automobile Garage, Buick.

Salt Lake City, Utah.—Booklidge-Gilmer Co., Croxton-Keeton.

Harrisburg, Pa.—C. C. Oyster, 9 North Market street, American.

St. Louis, Mo.—The General Motor Car Company, Hupmobile.

Seattle, Wash.—Overland Auto. Company of Washington, Overland.

Chicago, Ill.—United Motors Company, 1507 Michigan avenue. Sterling.

Minneapolis, Minn.—The Motor Sales Company, 409 Fifth street, S., Petrel.

Syracuse, N. Y.—Fred A. Marshall & Son, 231 Jefferson street, Hupmobile.

Walter C. Guilder, formerly engineer of the Plymouth Motor Truck Co., is now connected with the Garford plant in Elyria, Ohio.

George Soules, the well known racing driver, has joined the Overland Automobile Company, Toledo, Ohio, and will have charge of their testing staff.

Walter C. White, of the White Company, Cleveland, Ohio, will sail from New York on November 6 for his annual visit to the company's London branch.

Hayden Eames and Le Roy Pelletier, of the Studebaker Automobile Company, are at present making a trip to the branches of the company in the different large cities of the country.

G. H. Covert, Jr., has accepted the position of general manager of the Warner Motor Company, of Washington, D. C., succeeding A. Parker Warner, who will enter another line of business.

ner, who will enter another line of business.

H. W. Doherty, sales manager for the Cameron Car Co., Beverly, Mass., for the past two years, resigns his position with that company November 1. Mr. Doherty has not as yet announced his plans for the future.

The Toledo Times of October 17 contains a biographical sketch of President John N. Willys, of the Overland Automobile Company, who in a few years has built up one of the largest manufacturing concerns in the automobile line.

Charles R. Folsom has been appointed manager of the automobile fender plant of the C. G. Folsom Manufacturing Company, South Bend. Ind. The plant is located on West Sample street, near Union, and has been opened only recently.

Frank S. Davies has been appointed chief engineer of the Courier Car Company, of Dayton. Ohio. Mr. Davies was for several years chief engineer of the Pope Motor Car Company, of Toledo, Ohio, and then went with the De Luxe Motor Car Company, of Detroit.

A. D. Frost, formerly sales manager for the Harry S. Houpt Co., in which capacity he had charge of the distribution of the 1909 Herrestoff car, has been appointed sales manager of the Herreshoff Motor Co. of Detroit, Mich., whose output from now on is to be marketed direct from the factory.

W. S. Cranmer, who has been connected with various electric vehicle concerns for the past ten years, and lately with the Woods Motor Vehicle Company, of Chicago, has been appointed manager of the Woods electric department of the Moore Carving Machine Company, of Minneapolis, Minn. The company plans to install a full line of equipment for the care and repair of electric vehicles.

NEW YORK, NOVEMBER 3, 1909

**NUMBER 18** 

#### Calculation of Chassis Springs-I.

BY DAVID LANDAU AND ASHER GOLDEN.

One of the chief uses of a motor car is to give pleasure to its occupants. The occupants of a car do not derive any pleasure from its use unless they are comfortable, and nothing conduces to comfort so much as easy riding springs.

A great deal has been said and written on this important subject, yet it may be safely said that there is no other feature of the automobile about which so little is known. There are very few designers who can lay out a set of springs for a given car and feel assured that they will have the proper riding qualities; that is to say, that no alterations of any kind will be necessary after the springs are supplied by the maker from the designer's specifications.

When we speak of laying out a set of springs we mean to include, besides the data and dimensions usually found on blue prints, such other factors as the number of leaves, their thickness, the deflection under a given load (flexibility) and the material.

The data and dimensions usually found on blue prints which are supplied to the spring maker as working drawings are:

1. The projected length of the spring (main leaf) under load. 2. Opening or camber of the spring under load. 3. "Eccentration" of the spring centre; that is, the distances of the spring centre from the centres of the spring eyes. 4. Width of the leaves. 5. Load on each spring or per three springs if of the platform type.

6. Various details, such as the form of the spring eyes, size of bushings, form and number of clips, etc.

This information is supplied to the spring maker, whose knowledge and experience are to dictate the missing factors, such as the number of leaves, their thicknesses and the flexibility. In a few cases engineers attempt to take the spring maker by the forelock and specify the number of leaves, their thickness, the deflection desired under a given load; also the material, which is invariably "spring steel."

In many cases an order for springs is accompanied by a note to the spring maker to this effect: "We prefer to leave the number of leaves and their thickness to your judgment." The engineer would seldom include this note if he knew that the average spring maker knows very little more about such matters than he

does. This statement may seem to some to be very sweeping. That it is true will be seen from extracts of letters received from a number of spring makers in answer to inquiries for complete characteristics and prices of springs intended for a certain car. These letters of inquiry were sent out in the regular way by a well known automobile manufacturer in the effort to procure a good spring. These letters show that spring designing is a difficult art. The specification of the characteristics was evaded by the spring makers in practically all cases, and it was only after repeated inquiry that two or three specified the weight of the springs and nothing more. Such an important matter as the flexibility was not even mentioned.

The following are some of the replies received. We have italicized the important parts:

"In making springs we reserve the right to a difference of fifty pounds in carrying capacity of springs on account of the in-

"Your blue prints call for no particular carrying capacity, but we presume that these springs are wanted for a car of somewhat similar proportions to the X car. These springs, we expect, will weigh about 45 pounds per pair for fronts and 125 pounds per pair for backs.

"We are now making springs for the X people of dimensions similar to the ones you have submitted to us for their five-passenger touring car. If we have guessed rightly, our quotations will stand."

It must be remarked here that owing to an oversight on the part of the engineering department the blue prints were sent out without specifying the loads on the springs.

"We note the weight given on both front and rear springs. From this we can figure, with tolerable accuracy how strong to make your springs, so as to have the front springs sufficiently strong to hold the front of the car well in hand so as to steer easily, and your rear springs with sufficient elasticity to make the car ride easily.

"This, however, is a matter of estimate only, which can be verified only by trying out the first set on the road. It may then be found necessary to add or deduct a little weight from the springs so as to get them just to your satisfaction.

"As to the material of these springs, it is a high carbon steel of the best make. We can give you these springs made of alloy steel, which we are importing from Germany. We do not know the tensile strength of these spring steels, nor the elastic limit when tempered. Nor do such figures give any assurance of freedom from breakage or settling so far as we know. The springs, however, when made up, have a greater elasticity—greater than is likely to be called for in practice. As for alloy steel, the elastic limit in the springs is still greater."

This firm professes to know nothing of the material it uses other than that it is imported from Germany. The elastic limit for alloy steel is stated to be higher in the finished spring, although such figures give no assurance of freedom from breakage or settling.

"We will be very glad to make up one or more sets of either of these steels or both, and submit for your testing, inspection and tryout. If we do not succeed in fitting your car directly, we should be very pleased to make a second effort if necessary, as we are as careful to have then thoroughly balanced, and a proper capacity before we say they are right, before we feel they belong to anybody except us, and until that time comes the springs are on approval thoroughly and fully.

"When they shall have been perfectly satisfactory to both you and us, all the deductions you will be pleased to make can be made at your factory, regarding weights, fronts and rears, severally and collectively.

"The weight of the front springs per pair will be 44 pounds for open hearth and 41 pounds for vanadium.

"Weight of the rear springs per pair will be 90 pounds in open hearth, 87 pounds in the vanadium steel.

"I figure this spring should weigh approximately 180 pounds."

The springs, as finally made by the foremost spring manufacturer, weighed 157 pounds per set.

TEST DATA CONVENTIONS.

A test of a set of springs made by one manufacturer was reported as follows:

FRONT.

"2x8x36 at 3½ inch out x 5½ inch out, fa centre bolt, 2-3-3-4-4-4-4 steel, 5½ inch bush, true sweep, lips 3, clip 3d and 5th, two leaves drawn to end, short plate 12 inch.

"Test at 31/2 inch out 700 pounds. 400 pounds per inch.

REAR.

"21/4x7/6x441/2 at 85/2 inch in to out x 7

inch bottom, 8 inch top, 5% inch CB top, 18 CB 18 out bottom, 1-2-3-4-4-5-5-5 steel top, 1/2 inch bush scroll end, 5% inch bush front end, lips 5 top, lips 61/2 bottom, clip 3d scroll end, top and bottom, clip 2d and 4th front end, 7 inch flat top countersunk, 72 degrees 21/2 inch drop.

"Tests at 85% inch to out 890 pounds. 200 per inch."

On the receipt of this edifying information, a letter was written to the spring maker inquiring what it was all about, and the spring maker sent the following letter of information:

"We are in receipt of your favor of the —— and have carefully noted same. Regarding our letter of —— and test sheet covering the X car, I have noted your remarks and unless you have any knowledge of springs, the proposition is Greek solution.

"Now in regard to the front springs, the two indicated on the test sheet is the width of the steel. We read in this way, width of steel, No. of plates, length, at height given, normal height, grading of steel Stubs English standard gauge, and so on. Now to go into this matter, would say that this specification reads as follows: Two inch wide, 8 leaves, 36 inches long, at 31/2 inches over all, and that the original opening of the springs is 51/4 inch, that it is graded one plate of No. 2, two plates of No. 3 and five plates of No. 5 steel, that the spring is put up on a true sweep pattern or a pattern forming a certain radius of a circle, that the springs have side lips to prevent the leaves from sliding, and that the springs when deflected to a position shown on your blue print of 31/2 inches over sustain a weight of 700 pounds. On the rear springs these are read practically the same way.

"The leaves are 21/2 inches wide, seven plates on the top and eight plates on the bottom, 441/2 inches centre to centre, that it is 85% inches from spring seat to spring seat, or inside to outside measurement, as we term it, that the original opening of the top is 8 inches and the opening of the bottom is 7 inches, that there is a 5% inch centre bolt in the top and a fa inch centre bolt in the bottom, is inch off centre, that the top half is graded one plate of No. 1, one plate of No. 2, one plate of No. 3, and the balance of No. 4 steel, and the bottom is graded one plate of No.' I, one plate of No. 3, two plates of No. 4, and the balance of No. 5 Stubs English standard gauge, that there is a 1/2 inch steel bush in the scroll end, and a 5% inch bush on the front end, and that there are lips on five plates on the top and six and one-half plates on the bottom, which, by the way, are to keep the plates from sliding sidewise, or commonly called lugs, that the springs are clipped third top and bottom on the rear end and clipped second and fourth on the front end, that the top part is 7 inches flat for the spring seat, and that when the springs are compressed to 85% inches from the inside of the top half to the outside of the bottom half, or from spring seat to

spring seat, sustains a weight of 890 pounds, or 200 pounds per inch deflection. The 2½ inches drop indicated on this test sheet is the drop that the front end of the rear spring has from the centre line of the spring.

"We trust that with this information you will understand what the test sheet means, and if not, come back to us and we will endeavor to straighten you out. I hope within a short time to have a plain proposition which will obviate a lot of this trouble we are now having."

#### TEXT BOOK ADVICE.

The method usually employed by the average engineer or the average spring maker for the "calculation" of springs is shown very well in Strickland's "Petrol Motors and Motor Cars." Referring to the index we find "Springs, Calculation of Dimensions, 219." On page 219 we come across the following painstaking "calculation":

"A car weighing 18 cwt., and built for four people, had springs as follows: Front springs, single elliptic, 3 feet 4 inches long, 11/2 inches wide, with four leaves 1/4 inch thick. Back springs, single elliptic, with cross back spring, side spring 3 feet long, 11/2 inches wide, and five leaves 1/4 inch thick. Cross back spring same dimensions as side springs. The springs were tempered fairly hard, and gave pretty easy running, but were too jumpy. They were softened till quite soft, and three leaves were added to each of the back springs. and two leaves to each of the front ones. The result was that the springs were just about as strong as before-i. e., gave just about the same amount under the same load. but the increase in comfort in the car was very great. It will be evident from the above that no formula can be given for the strength of springs, unless the exact nature of the steel they are made of is known. The above, however, proved very satisfactory."

We confess to our inability to see how, if the springs "gave just the same amount under the same load," the riding qualities of the springs were improved. In regard to the statement that no formula can be given for the strength of springs without a knowledge of the materials of which they are made, it should be remarked that a formula for the strength of a spring, like formulas for the strength of other parts, is not a function of the properties of the material, but depends on the shape of the section and the distribution of the surface of the section about the neutral axis. A formula for the strength of a spring is given in the course of this article.

At the July, 1907, meeting of the Society of Automobile Engineers, during the discussion of a paper on "Motor Vehicle Springs," one engineer remarked:

"There are almost no data in the text books or elsewhere that are of any real value in laying out a set of springs for a vehicle, and the quickest method I have found is to measure up the springs on a number of similar vehicles and then make a close guess, and afterward change them until you get them as nearly right as possible. I have talked with a number of engineers, and that seems to be the general practice. There is a great deal of doubt and haziness in regards to spring data and materials."

The engineer is very fortunate who can find vehicles similar in every respect to his own. Moreover, he must be an adept at the art of guessing right. Besides, what assurance is there that the similar vehicles will have good suspensions—some may be too hard, other too soft.

#### A SUCCESSFUL EXPERIMENT.

Our own experiments to find an easy riding spring for a certain runabout are of interest. During the early part of 1907 a number of sets of springs of the following dimensions and characteristics (all of which were specified and supplied to the maker) were ordered of a certain spring manufacturer, and one of them placed on a chassis for testing. After a fair run over rough roads it was reported that the springs were too stiff

	Front.	Rear.
Type of spring	Semi-elliptic.	Semi-elliptic.
Length under load	341/2	4134
Opening under load.	31/2	4%
Width of leaves	134	134
Number of leaves	5	5
Load on each spring,	-	
pounds	375	375

Thickness of leaves. { 9-32 in. top, re- 5-16 in. top, re- mainder, 1/4 in. mainder, 1/4 in. Material (as usual), "spring steel."

The front and rear springs were found to have a flexibility of .21 inch per 100 pounds and .398 inch per 100 pounds, respectively, as against .28 inch and .51 inch specified for the same car by a well known manufacturer. The latter flexibilities were assumed to be correct in order to give us a working basis for the determination of the flexibilities to suit our particular case.

Experiments were begun by removing the middle leaves of all the springs. The springs were then replaced and the car was taken out over the same roads. The springs were reported as being very satisfactory. The flexibilities were again measured and found to be .292 inch per 100 pounds for the front and .512 inch per 100 pounds for the rear. It was a happy strike that gave us, as the result of a single experiment, a flexibility which was practically the same as our basis. This simple test enabled us to specify the flexibility-practically the only unknown factor in the design of a springor, in place of this, the exact number of leaves and their thickness. There is no reason why the spring maker's experience should not have dictated the proper flexibilities from the data and dimensions which we submitted. We were surprised to find that on putting a second set of springs through the same test and removing the middle leaves the result was entirely different, so that the fault was evidently with the materials and the condition of the surfaces of contact of the leaves.

(To be continued.)

# GREAT QUESTIONS OF AUTOMOBILE ENGINEERING.

#### Introduction.

Despite the very strong tendency lately manifested toward uniformity of practice in automobile engineering the methods adopted by various manufacturers to accomplish the same technical ends still exhibit plenty of diversity.

These diversities in practice are the tangible expression of the fact that there are certain important engineering problems which are as yet unsettled, so that one engineer prefers a certain solution while his neighbor adopts a different or a contrary one.

Such alternative methods form the subject matter of endless discussions upon the part of all who are technically interested in the automobile, but it is hardly to be believed that the superiority of one method over another can ever be demonstrated on a priori grounds. Long continued "trying out" in everyday service must be the final arbiter, and, indeed, it is doubtful whether one method will ever prove universally to possess any intrinsic balance of advantages over the alternative practice, for circumstances of use and the manner in which each method is carried out may render one superior under one set of conditions and the other most satisfactory under its own appropriate circumstances.

In general, where alternative methods are in vogue, both answer the purpose in a fairly satisfactory manner, for were this not the case it is obvious that one method or the other would have become obsolete before this rather advanced period of the industry.

While it may be admitted that the final settlement of the superiority of one method over its alternative or alternatives is beyond the present ability of any engineer, and to be reached only through the results of future experience, it is possible to bring together, in compact form and in an impartial spirit, the chief arguments which are adduced pro and con. these alternative methods by their supporters and detractors, thus placing the matters in contention in such shape that the reader may weigh the evidence and form his own verdict as to which possesses the balance of merit, as viewed from his own standpoint.

It is exactly this which is attempted in this series of articles upon "Great Problems of Automobile Engineering."

## Air Cooling versus Water Cooling. By Albert L. Clough.

The ends which an engine cooling system is designed to attain are as follows:

- (1.) To maintain the cylinder and piston at a temperature at which the action of a reasonable quantity of oil will insure effective Inbrication.
- (2.) To prevent relative expansion and distortion of the piston and cylinder under

the heat of the combustion, which would result in undue friction, and to prevent valves from warping and pitting from the same cause.

- (3.) To limit the temperature to which the charge is subjected to a value at which self ignition cannot occur.
- (4.) To minimize the preheating and consequent reduction in energy value of the entering charge.

It is claimed for each system of cooling that all these ends are attained by it in a satisfactory manner. In a general way air cooling is claimed to secure the desired results in a simpler and more direct manner than does water cooling, while on the other hand the supporters of water cooling insist that their system insures much more reliable results and possesses a greater factor of safety to cover unskilled handling and excessively arduous service.

Among the points of superiority which are cited in favor of air cooling are the following:

That the directness of the system, attained by allowing the cooling medium to come directly into contact with the surfaces to be cooled and to abstract from them the necessary amount of surplus heat, permits of the elimination of considerable apparatus which otherwise is required. The radiator, with its fragility, liability to leakage, cost and weight, is dispensed with; the pump, with its driving mechanism, is done away with, and the equipment relieved of just so much complication and the operator of the required lubrication and repackings.

All water piping, with its tendency to leak and to render the parts of the motor less accessible, is avoided. No water jacket being provided, the cylinder casting is simpler and lighter and more readily inspected for defects.

Air is a cooling medium which is always at hand in infinite quantities, while water is only to be had at certain points, and the supply on hand must be maintained by the operator at some little bother.

It is claimed that by the adoption of air cooling the power plant is rendered more simple and lighter by the amount of the water carried, the pump, piping and radiator, and that the ability of the vehicle is consequently increased, while the operator is at once relieved of all care concerning his cooling system, since there is nothing to leak or boil away and require replenishment. No liquid being used as a cooling medium, there is nothing to freeze and burst the walls of the system, and thus the car may be used in any weather, no matter how cold, and may be stored in an unheated stable without any precautions being necessary.

The advocate of air cooling holds that the simplest method capable of affording satisfactory results is the best, and that the use of a water circulating system to convey the heat from the point of its development to a special radiator and there dissipating it is a sort of a mechanical journey "around Hobin Hood's barn."

He claims, furthermore, that while air cooling reduces the cylinder temperature to a perfectly safe point it does not overdo the matter, but keeps the walls at a sufficiently high temperature so that the heat losses therethrough are limited to a practical minimum. This results in the attainment of higher mean effective pressures and a much higher fuel efficiency.

It is asserted in this connection that a vehicle engine is most efficient when its cylinder wall temperature is about 350° Fahr., and that it is impossible to realize so high a temperature when water jacketing is adopted, since water boils at 212° Fahr.

As practical examples of the superiority of air cooling, its devotees point to a transcontinental record held by an air cooled car to the performance of "direct cooled" cars in Glidden Tours which have involved supremely arduous driving conditions, and also to the success obtained by a large numof private users who operate their cars in winter as well as in summer. They also cite the consistent victories of air cooled cars in the principal fuel economy tests.

Turning to the claims of the water cooled contingent it is found that they also present a strong case, among the items of which are the following:

That water cooling, so long as the system is rightly designed, kept well filled and an active circulation maintained, does not permit of the attainment of cylinder wall or valve pocket temperatures of more than a few degrees in excess of 212° Fahr., at which temperature neither faulty lubrication, binding of the parts nor self ignitions can occur. The water may gradually boil away, but no matter how unskilled the operator may be, how much he may run on an unnecessarily low gear, or how much he may mishandle his throttle and spark lever, the motor cannot be overheated to the point of serious reduction in power or complete "lying down." In other words, that a margin of cooling capactity is provided which is possible only in a system employing a circulating medium possessing a maximum attainable temperature, fixed by its physical properties.

There are two other claims based upon this assumption that a water cooled cylinder cannot greatly exceed the boiling temperature, namely: First, that a higher compression pressure may be carried therein than could safely be allowed did the temperature rise to higher values, as in an air cooled cylinder. This assertion is based upon the fact that the likelihood of self ignition at a given gas pressure is greater in proportion as the temperature of the gas

is higher. The advocate of water cooling takes the ground that the higher compression pressures practicable under his system are of decided thermodynamic advantage. Second, that with the cylinder walls maintained at a temperature hardly exceeding 212° Fahr., there is but slight preheating of the charge, as compared with the preheating suffered in the case of a cylinder operating at a much higher, variable temperature, and that consequently the water cooled cylinder draws nearly its full theoretical weight of mixture each stroke, and its output per cubic inch of piston displacement is thus greater than is that of the hotter cylinder.

It is also asserted that the water cooling system permits of more readily regulating within safe limits the temperature of the valves without recourse to unusual valve arrangements and special provisions for disposing of the exhaust. By water jacketing the valves it is claimed that greater reliability and freedom from distortion and burning is obtained than by a dependence upon air cooling.

As a practical indication of the superiority of water cooling, its supporters call attention to the fact that its use enormously preponderates over that of air cooling, that all speed records have been achieved by water cooled cars, and that a number of manufacturers formerly building air coolers have renounced the method and adopted water cooling.

The disadvantages of air cooling, as set forth by its detractors, include the following, and it is only fair to state that it is highly questionable whether they all apply to the better class of air coolers:

That while air cooled cars may be made to give excellent results in the hands of experts or skilled operators, the margin of cooling capacity is too restricted successfully to meet deranged conditions of the carburetor, excessively severe driving conditions in hot weather and the mishandling due to an unskilled operator. Under such abnormally adverse conditions it is claimed that the air cooled motor is prone to run too hot, and to preignite and to lose power through charge reduction.

The belief is also still held, in some quarters, that air coolers require an excessive quantity of lubricating oil to insure successful operation, the lubricant being more rapidly evaporated from the cylinder walls and ejected with the exhaust or burned as a component of the mixture than is the case with water cooled motors.

Greater liability to valve breakage, distortion and scaling are also vices which are still held to appertain to the air cooler, while it is furthermore asserted that the average air cooled motor is less quiet in operation than the average water cooler under similar circumstances.

The restriction of air cooled practice to relatively low compression pressures and the undue reduction of the charge ratio on account of preheating also constitute objections raised by the members of the opposing school.

Extreme sensitiveness to excess surplus heat given to the cylinder walls by slow burning mixtures and weak or unduly delayed ignition is also said to characterize the air cooler and to lead to its faulty performance under hard service.

The air cooled contingent reply to their rivals by asserting that the margin of cooling which its system affords is sufficient to meet practical requirements and that its use relieves the operator of all anxiety upon the score of cooling; that it is unnecessary to deal with objectionable cooling liquids or to take any other cold weather precautions. They assert that it is as foolish as it is unnecessary to cumber the car with a "plumbing job" and that the dead weight of the water cooling system is a serious drawback. They assert further that heat losses to a cold cylinder constitute a constant and very substantial demand upon the fuel tank which the air cooling system materially reduces, and they also cite figures from economy tests to prove that the assertion that an air cooled motor is in reality an "oil cooled" motor is a pure fabrication.

## Official Trials of Individual Cars by the Automobile Club of France.

The technical committee of the A. C. of France have decided to superintend trials of individual vehicles by manufacturers under conditions which the committee will determine after having been informed of the tests which the manufacturer desires to have carried out. The technical committee may designate official delegates for road trials who will be selected from a list of names established by them. These delegates will be furnished for each trial with a question blank which they must fill out, and the duties of the delegates will be limited to determining the answers to the questions contained in the blank. The delegates are not allowed to modify the questions in any way, which, moreover, must be accepted beforehand by the manufacturer. After having gone over the replies to the questions written out by the delegates the technical committee will draw up its report, which will remain the property of the manufacturer, and will be published only with his consent, and, after a decision to that effect has been taken by the committee, in the official bulletin of the committee. The expenses of the delegates during the time of the trial must be borne by the manufacturer. A charge of 50 francs per day is made for the delegate and 10 francs per day for the work of the committee in drawing up the report. During the time of the trial the delegate is considered in the employ of the manufacturer, and all civil and penal responsibility rest upon the latter. Such officially supervised trials have for years been conducted in England, and British makers and agents have frequently availed themselves of the opportunity thus offered.

#### Some Repair Shop Notes.

CHANGING INNER TUBES UNDER DIFFICULTIES.

While making a road test of a car to be used in a race the testing crew from one of the better known factories had the misfortune to get a puncture, and discovered that they had nothing to repair the damage except a spare inner tube—no tire tools, no jacks, and the nearest garage miles away. The tire was first worked off by hand and the car then blocked up with the aid of stones and a fence rail. The tire with the new tube in was then worked back on, and the return run was safely made, but on all succeeding trips a full set of tools and spares was carried.

#### DOUBLE GAS LINES TO HEADLIGHTS.

One of the firms which take part in twenty-four hour and other long distance races requiring driving in the dark finds it a great advantage to run duplicate gas tubes to the lights. In their past experience they have often suffered much inconvenience when the racing extended into the night, from accidents to the lights, and the liability of such accidents is greatly reduced by double piping. They also run the tubes exposed where they are easily accessible, and tape them so that even if a leak develops it may not put the line entirely out of commission.

#### REMAGNETIZING THE FORD MAGNETO.

The field magnets of magnetos occasionally become weakened, owing to road vibration or from other causes, and the Ford Motor Company has worked out a simple plan for remagnetizing the fields of its flywheel magneto when they begin to show signs of weakness. This consists in sending current from a 6 volt storage battery through the armature coil and taking care that the north poles of the fields are opposite the south poles of the armature. The current is not passed continuously, but the circuit is rapidly made and broken, and in this way, we are told, the field magnets can be restored to their full strength in about half an hour. Great care must be exercised to get the field and armature poles in the proper relation before applying the battery current, as otherwise the field magnets may be entirely demagnetized. The north poles and south poles of the armature and field can be determined by means of a compass.

#### A DISC CLUTCH REPAIR

In a certain make of car equipped with a disc clutch it is found that the operating fingers and pressure plates sometimes become worn at the points of contact, so that it is impossible to properly engage and disengage the clutch. This trouble has been remedied by a New York shop by tapping and drilling the operating fingers and inserting set screws. The set screws are provided with jam nuts, and the fingers are then easily adjustable for wear. The method has been applied to a number of cars, and is said to have proved entirely satisfactory.

#### New Article Series.

In the present issue we begin a series of articles under the heading "Great Questions of Automobile Engineering." This series covers such subjects as Air Cooling vs. Water Cooling, Shaft Drive vs. Chain Drive, High Tension vs. Low Tension, Ignition, etc. These articles are written, not with the intention of aiding the engineer in solving these problems, but for the benefit of automobile sellers and buyers-salesmen and their customers-in whose intercourse these questions come up for discussion every day. The articles are designed to acquaint the readers with all the strong and weak points of each system of construction and should prove invaluable to those intending to purchase cars the coming winter or spring, as well as to the sales-

The articles will be written from an entirely unbiased standpoint, the writers confining themselves to an exposition of the

claims made by the champions of the different systems, and of the objections raised by them to the rival systems, so far as these claims and objections have a semblance of validity. Although the discussion will be entirely non-partisan, in cases where objections have been made to one system or another, that never had any foundation in fact, or which no longer apply, this may be pointed out. In case a good point of any system should be inadvertently omitted or objections should be named which are obviously foundationless, our readers are requested to call attention to the fact.

#### International and Interstate Recognition of Automobile Licenses.

Several of the leading European nations at a convention held in Paris during the first half of the past month subscribed to an agreement whereby a motorist who has complied with all the legal requirements in his home country will be permitted to drive in any of the other subscribing countries without any formalities, provided he attaches to the rear of his car, in addition to his regular registration number tag, a tag bearing a letter designating the country of his residence. A complete report of the sessions of the convention was printed in our last week's issue, and the agreement is printed in full in this week's issue.

The matter is of direct interest only to a relatively small number of American motorists, but we believe that the agreement can be used to good advantagein furthering the movements in favor of Federal registration and interstate recognition of automobile licenses. It is interesting to note that the United States, although represented at the congress, did not subscribe to the agreement. Our delegate, W. S. Hogan, will make a report of the convention to the Government at Washington. There is, of course, some question as to whether the National Government can consistently enter into such an agreement. If it should do so it would be a recognition of automobile traffic as interstate commerce, and the action of the Government would at once sweep aside all objections which have hitherto been raised against a Federal registration law. If the Federal Government possesses the power to give permission to foreign motorists to drive in any State of the Union without registering in that State, then it certainly also possesses the power to grant the same permission to native owners of cars.

In view of the fact that only few Americans would be benefited, and the further fact that some rather delicate questions of jurisdiction are involved, it is very questionable whether the United States Government will subscribe to the agreement drawn up at the convention, especially as probably no particular pressure will be brought urging it to do so.

But the removal of the barriers to auto traffic at national boundaries in Europe ought to be an object lesson to those of our State Governments which still refuse to recognize the auto licenses issued by their sister States. If these different nations, between whom there are no particular ties, are willing each to admit the motorists of the other on the strength of the licenses which these motorists have procured in their own country, how much more willing should our State Governments be to accord the same courtesy to motorists registered in neighboring States! With the rules of the road the same throughout the country there is no more danger of accidents being caused by non-resident than by resident motorists, and the chances of abuse of the privileges accorded by such mutual recognition of auto licenses are certainly less here than in Europe.

# The Increasing Popularity of the Six.

Among the many new models which are being announced for the coming season there appears to be an increasing proportion of six cylinder machines. While the four cylinder motor will evidently, as in past seasons, be by far the most popular type, there seems to be a growing class which demands the luxury which the six cylinder construction probably gives in its fullest measure.

Theoretically the more uniform torque and the almost equal balance of the six cylinder motor make it a far better type than the four cylinder. As the standard of workmanship in our shops has increased, and as ignition systems have become more reliable, the chief former objection to the six cylinder motor, i. e., the difficulty of getting all six cylinders to work in synchronism, has, to a large extent, disappeared. While these same conditions have made it possible for makers to turn out better four cylinder motors, the improvement in sixes has probably been more marked, and has no doubt had its influence in deciding some makers to enter upon their manufacture. There is no doubt but what the six cylinder motor

can be satisfactorily run at a somewhat lower speed than can the four; probably it is also capable of somewhat higher speeds than the four without excessive vibration, since the resultant inertia effects do not increase so rapidly as with fewer cylinders.

But this latter quality is of questionable value, as the four cylinder motor will run fast enough without undue vibration for any reasonable use. Indeed, as far as vibration effects on the occupants of the car are concerned, there is at the present time little, if any, advantage in using six rather than four cylinders, unless the motor is unusually powerful in relation to the weight of the vehicle.

The advantages of the six must then lie entirely in its greater flexibility. And by "flexibility" we mean both the range of speed and the promptness with which the speed can be changed. Just how great the advantages of the six are in this respect is evidently a matter which can only be decided by the users.

When six cylinder motors first began to make their appearance several seasons ago it was freely prophesied that they were a fad and would soon disappear from the market. But the same thing was said about the four cylinder motor when it first began to come into competition with the two cylinder opposed. The four cylinder has greatly increased its popularity in spite of these prophecies, and the same may be said, though in a lesser degree, of the six. The automobile industry is still young. Many think that we will use motors with fewer cylinders in years to come; perhaps they are right. On the other hand there is no particular reason for stopping at six cylinders-the eight cylinder V motor is somewhat smoother than the six, and so on.

Each cylinder we add makes the motor somewhat smoother running, and at the same time somewhat more complicated. There is only one authority who can finally decide the balance of advantages and disadvantages of the different types, and that is the user. Evidently enough users think that there are advantages in the six cylinder machine to create an increasing demand for that type, but, as we said before, the popularity of the four is in no apparent danger.

#### Questionable Value of Rumors.

There are always a great many rumors going the rounds as to the new constructions which are being tried by various prominent companies. Unfortunately, these rumors are often used by the smaller com-

panies as the basis for much of their experimental work. As a matter of fact, the large makers, whose output is sufficient to warrant their spending considerable money in research, are constantly trying all sorts of constructions, some of them very unpromising, in the hope of discovering something of value. These experimental constructions are often reported to have shown a great deal more merit than has actually been the case, and the smaller makers, acting on these reports, often engage in costly experimental work which is largely wasted.

This is by no means intended to discourage experimental work, for the new things which are developed from day to day in that way add much to the importance of the industry; it is written rather with a hope of increasing the amount of consideration given a problem before the actual work is commenced. Often only a rough analysis of the conditions is needed to show that it will be useless to start the work. It is our earnest belief that most of the money spent in experimental work could be utilized to better advantage if more time were given to a preliminary consideration of the problems presented. Too much attention should not be given to reports whose optimistic tone is perhaps intentional.

#### Quiet Shifting of Clash Gears.

The noise accompanying the meshing of gears has always been very properly regarded as an objection to the sliding gear system of speed changing. Objectionable as is the noise per se, its most serious aspect lies in the fact that it is the audible indication of severe stresses and wearing actions within the gear box, which may in time lead to failure of the gear set.

Noisy gear changes do not seem to be a defect of cars of cheap construction only, but are to be noted in connection with cars of the highest grade.

Probably the skill of the operator is the most important factor controlling this matter of noise in gear shifting, for it is observable that an experienced operator can usually make all changes with very little clashing, while a novice is likely to make very noisy changes, no matter what car he is attempting to drive.

An enormous number of cars, equipped with sliding gear sets, have been produced this year, and a large proportion of these has been delivered to owners who either are new drivers or who have previously driven cars with planetary gears. Quite a large proportion of these operators are

rather slow to acquire the skill necessary to avoid clashing, which is a matter of simultaneously judging car and engine speed. It is no wonder that a good deal of decidedly nerve racking gear clashing is heard at the present time.

While it is doubtful if the sliding gear system can be "foolproofed" to such a degree as entirely to overcome the effects of unskillful handling, quiet gear shifting may be greatly promoted by care in the design and construction of the gear set and its connected parts, and it is certain that the sliding gear system may be so arranged that the skillful operator shall have no trouble in making noiseless changes.

In the announcements of 1910 models many references will be found to this matter, and many claims will be noticed that gear clashing has been rendered impossible through improved construction, from which allusions it is evident that manufacturers are giving earnest attention to the question.

The recent development of machine tools for accurately and inexpensively beveling the abutting ends of the teeth is proving of great assistance to manufacturers in rendering their gears more readily meshable, the process of beveling having previously been mostly accomplished by hand in a somewhat inaccurate and very laborious manner.

Renewed interest seems also to be shown in the clutch brake, the employment of which renders decidedly easier the change from lower to higher gears, and this device is being adopted by some manufacturers who have hitherto not employed . Designers also are doing away with the diagging" which is a defect of certain topics of clutch, and which is a serious clut quiet gear shifting, and at the the reduction of the moment of mertis of the member of the clutch which is upon the gear shaft is being carried as far as practicable, in order that the speed of the idle parts may be readily and quickly alterable to the proper meshing value.

These improvements are of the greatest value in the elimination of gear clashing, but the education of the operator is essential before quietness of gear changing shall become universal. Perhaps the driver will educate himself in the school of experience in time, but a little more careful instruction on the part of the agent or salesman than is usually accorded would tend to hasten the acquirement of the necessary skill. This would tend to save the gears and to obviate one of the popular objections to cars.

# The Vanderbilt Cup Race

#### and the Wheatley Hills and Massapequa Sweepstakes.

Harry F. Grant, driving an American built Alco six cylinder, 60 horse power stock car, won the fifth annual race for the William K. Vanderbilt, Jr., Trophy, on the Hempstead Plains circuit, on Long Island, on Saturday, completing the 22 laps, equal to 278.08 miles, in 4 hours 25 minutes 42 seconds, at an average speed of 62.8 miles per hour. This is within two miles per hour of the stock car record of the world. Only five minutes behind Grant was Edward H. Parker in a four cylinder, 45 horse power Fiat, whose time was 4 hours 30 minutes 57 seconds. Up to the very finish of the race it was expected that Parker would be the winner. At the end of the nineteenth lap it appeared from the announced times that Chalmers-Detroit, No. 7. with "Billy" Knipper driving, was in the lead, leading Parker in the Fiat, No. 14, by about five minutes and the Alco, which appeared to be in third position, by about fourteen minutes. When the Chalmers-Detroit failed to put in an appearance on its twentieth round it was officially announced that the Fiat was then leading and that its time for twenty laps was 247 minutes 12 3-5 seconds. Several private clockers had observed that the official timers had failed to catch Grant on the eleventh

#### SUMMARY OF THE RACE.

#### CIRCUIT.

Location of circuit, Hempstead Plains, Long Island. Length of circuit, 12.64 miles. Road surfaces, concrete, macadam and dirt road.

lap and set down his time for twelve laps as that for eleven laps. The time announced for Grant's tenth lap was 125 minutes 27 seconds, and for eleven laps 147 minutes 25 seconds, so that his time for this lap would have been 21 minutes 58 seconds. Grant made the next lap in II minutes I 2-5 seconds, or almost exactly one-half the time put down for his eleventh lap. When the matter was brought to the attention of Arthur N. Jervis, who was in charge of the Alco camp, he at once lodged a protest with William K. Vanderbilt, the referee. After a hurried consultation of the officials the protest was granted and the Alco was conceded one more lap than it had been credited with up to that time. Almost immediately after the protest had been allowed the Alco passed the grand stand and Starter Wagner gave Grant the signal for the "next to last" lap. This created much confusion in the grand stand and among the press representatives, most of whom had not yet heard of the protest and from the announcers' statements were under the impression that Grant had still two laps to complete.

If the fifth running of the race for the Vanderbilt Cup did not compare favorably with most of its predecessors, there are

SECTION OF THE COURSE, LOOKING TOWARDS HICKSVILLE.

a number of weighty reasons which account for the fact. In the first place, its entire character was changed this year; by the rules it was a national stock chassis event instead of an international racing car Derby, and the spice of patriotic sentiment was therefore lacking. Secondly, the date was set too late in the season for the race to be viewed by the spectators with any degree of comfort. The grand stand is evidently erected for summer use, with a roof designed to shield the occupants from the sun, but on Saturday a little sunshine was a real blessing, and those who had paid high prices for seats and boxes in the grand stand suffered more discomfort than those who camped in the open fields along the course. Finally, the time of preparation for the race was exceedingly short, the event having been definitely decided upon barely a month in advance, and the Motor Cups Holding Company, which conducted the race, was gaining its first experience, at least as an organized body.

In view of the late date the start of the races was set for 9 o'clock a. m., and this arrangement changed the entire aspect of the preliminaries to the race. Although all of the hotels in Garden City and the other towns along the course were crowded, there was little camping along the course during the night before the race that formed such a conspicuous feature of the previous Vanderbilt races. The night air toward the end of October is generally too chilly to make such an experience enjoyable and the late start rendered it unnecessary. But in the early morning hours the customary exodus to the race course started from New York and Brooklyn-by auto, by train, by carriage, and from the nearer points on foot. However, the attendance was by no means as large as during the past two years. It would be idle to speculate regarding the number of people

HARRY F. GRANT IN ALCO WINNING RACE. Showing the grand stand and pits.

who lined the course. The grand stand was approximately half filled at the time of the start, but many left it before the chief race was half completed, partly because the race itself was not sufficiently interesting and partly because of the chilly weather.

The start began promptly at 9 o'clock, the entrants in the two minor events being sent away first, at 15 seconds intervals. The contestants for the Massapequa sweepstakes contest were started beginning at 9 o'clock, those for the Wheatley Hills sweepstakes contest at 9:02 and those for the Vanderbilt Cup contest at 9:04. All of the entrants started with the exception of Willie Haupt, in the American, No. 2, who was prevented from taking part by an accident during practice on Friday morning

in which the crank shaft of his motor was broken.

Bert Dingley was replaced by "Billy Knipper as driver of the Chalmers-Detroit, No. 7. Dingley had an accident during practice one morning early in the week and received more or less severe personal injuries. He made a trial run on Friday morning, but found that he was not in condition to drive in the race, and Knipper was then assigned to his place.

The first car to complete the first lap was the Chalmers-Detroit, driven by Joe Matson, who started third. The second around was also a Chalmers-Detroit, that driven by W. R. Burns, who started first. The cars followed in quick successsion, and from that time on the bugle blasts announcing the approach of cars came at such frequent intervals that there were never any tedious waits. The best time in the first lap was made by Wishart (Mercedes), viz., 11m. 10s.; second best by Louis Chevrolet (Buick), viz., 11m. 21s., and third best by Joe Seymour (Isotta), viz., 11m. 30s. In the second lap Chevrolet obtained the lead. followed by Knipper in the Chalmers No. 7 and Wishart in the 1903 Gordon Bennett Cup winner, Mercedes.

The first car out of the race was the Simplex, driven by Mitchell. While on its third lap and in a position near the head the crank shaft of the motor broke and Mitchell was out of it. The accident occurred only a short distance east of the grand stand. It was Mitchell's first experience in road racing, and he was keenly disappointed at his early elimination.

The spectators in the vicinity of the grand stand had their first thrill when S. E. Wishard, in the Mercedes No. 16, overtook the Marmon No. 32 at the end of the fourth lap in front of the grand stand. A moment later a wave of enthusiasm was set in motion by the announcement that Louis Chevrolet (Buick No. 15) had covered his

START, VANDERBILT CUP RACE.

lap in 9 minutes 57 seconds. This if to a speed of 76 miles per hour.

31, the Marion entry in the Wheatley Sweepstakes, stopped at the end of its p at the pits in front of the grand owing to some trouble with the monich took 9 minutes to correct. E. A. e., the amateur driver of Fiat No. 4. If at the pits at the end of his second I was detained 4 minutes with engine

5 minutes to 10 the Atlas entry No. the Fiat No. 14 raced by the grand "neck to neck," the Atlas seemingly g its own quite well. This machine always be recognized as it approached ess stand before it could be seen by uliar exhaust noise. The exhausts of the cylinder two cycle engine came so ogether as to produce one continuous g noise in which one explosion could distinguished from the other. The carents the firm's first attempt in road

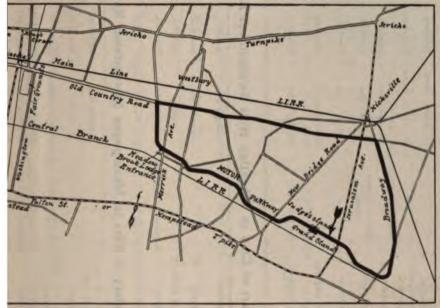

PARKING SPACE NEAR GRAND STAND.

A little later came the report that the Buick No. 15, driven by Louis Chevrolet, had ing point and viewed the rest of the race from the Buick pit.

At the end of the tenth lap the race seemed to lie between the two Chalmers-Detroit "Bluebirds," Nos. 7 and 9. No. 7's time for ten laps was 113 minutes 52 seconds, and No. 9's 114 minutes 36 seconds. Their nearest competitor at that stage of the race was the Apperson No. 6, driven by Hugh N. Harding, whose time for ten laps was 119 minutes 37 3-5 seconds; then came the National No. 11, driven by Charles C. Merz, and the Alco, driven by Grant. A short time later came the report that the Apperson No. 6 had turned over at Massapequa Lodge, but that no one was hurt, and the latter part of the report received confirmation later on by Harding appearing at the starting point.

No. 7, the leading Chalmers-Detroit, stopped at the pit at 11:15, at the end of its twelfth lap, and renewed both rear tires. A peculiar device was used for raising one end of the car instantly. It consists of a steel bar bent into such form that its two ends may be inserted under the ends of the axle and then by pulling down on the middle of the bar the end of the car is

blown out a cylinder at Middlebrook and was out. Chevrolet returned to the start-

and made a very good impression. is Strang had a thrilling experience the second lap. While driving at full at Meadowbrook a stone that had been n on the course by a spectator boundand struck his radiator, causing a Strang continued to the end of this d stopped at the pit, where an examiof the car revealed a broken steeruckle, which forced him to withdraw. Moon No. 34 stopped at the end of irth lap at the pit and put on a new of spare covers. It had been running consistently up to this time, covering st two laps in about 15 minutes each, e next two in about 14 minutes each. e later the Isotta No. 17, driven by eymour, was pushed off the course at rand stand with a broken steering It had completed six laps,

Marmon No. 12, driven by Harry Stillwas reported out of the race at 10:30 a broken steering knuckle. Stillman ampleted five laps in 63:34 2-5, which ponds to a speed of 60 miles per hour.

raised and the device serves as a prop. In this case, however, the car had been driven very close to the curb, and as the device lifts the wheels only very slightly off the ground it was impossible to get the near tire off until that side of the car had been further raised by means of an ordinary jack.

At the end of the thirteenth round the field in the Vanderbilt Cup race had been reduced to five contestants. The Chalmers-Detroit No. 9 blew out a cylinder between Westbury and Middlebrook on its thirteenth round. The National No. 11 also failed to complete its thirteenth round. The other National, No. 10, had lost a wheel at Middlebrook early in the race, but the fact was not announced at the grand stand until the leaders had completed five laps.

At 15 minutes to 12 the Atlas, at the end of its tenth lap, stopped at the pits and took on fuel, oil and water. The exhaust of this car, which is very characteristic when the motor is working under full load, is equally so when it is throttled down. The charge distribution then appears to be more or less irregular, and misfires alternate with explosions of considerably varying force, to judge by the noise of the exhausts. At the same time as the Atlas the Alco made a stop at the pit and put new tires on one front and one rear wheel. The demeanor of Grant during these stops at the pits differed considerably from that of the other drivers. He appeared to be absolutely cool, calm and collected, not at all in a hurry, and at his first stop for supplies some of the spectators got the impression that he was about to retire, so entirely devoid of any suggestion of rush were his movements, but when he passed the grand stand on his next lap it was quite apparent that he was still very much in the race.

At 12 o'clock No. 7, the Chalmers-Detroit, driven by Knipper, stopped at the pit to change a front tire. It had completed fifteen rounds at an average speed well below 12 minutes to the round, and had apparently a safe lead over its nearest competitor. In the rush to get off again it was forgotten to remove the special jacking device above alluded to, and had not some bystanders called the driver's attention to the oversight just as he was ready to let in the clutch the car would probably have moved off with the front on a sort of sleigh runner.

At 12:35 it was reported that the Knox No. 5, driven by Elmer Knox, was off the road at Hicksville, and it was then feared that this car, which had been running quite consistently during the first part of the race. though its speed was not quite high enough to give it a chance for the cup, might be out of the running. These fears were dispelled when the car came by the grand stand again on the completion of its tenth lap, for which it required 47 minutes.

The Alco made another stop for tires at 12:35, and a couple of minutes later the leading Chalmers-Detroit, No. 7, drew up to the pit again to replenish its supplies of fuel and oil. Time was now precious. The Fiat No. 14, second in the race so far as

then known, was only to minutes behind, and four laps still remained to be run. In a few minutes Knipper was off again. At this time five cars in the Vanderbilt Cup race were still on the course, namely, the Chalmers-Detroit No. 7, the Fiat No. 14, the Alco No. 8, the Mercedes No. 16 and the Knox No. 5. As the times were announced the contestants then followed one another in the order given, but making correction for the losing of one lap of the Alco by the

those most interested, and not the least among the photographers who had their cameras set in preparation for snapping the finish of the winner. Parker's time for the twenty-two laps was 4 hours 30 minutes 57 seconds. Immediately upon the completion of Parker's last lap the race was called off. Of the Vanderbilt contestants S. E. Wishart (Mercedes) and Elmer Knox (Knox) were still running.

Practically the whole interest of the

KNIPPER IN CHALMERS.

scorers the latter was already in second position. Knipper completed his nineteenth round in 2:30:43, and then was not seen again, nor was anything heard regarding the cause of his disappearance until the finish of the race. It was then learned that he was detained by a burnt out bearing, due either to an air lock in the oiler or to failure to replenish the oil supply in time.

The Alco protest and its allowance caused a big surprise to everybody and a great deal of confusion reigned for a while among crowds was monopolized by the big cars contending for the Vanderbilt Cup, and the finishes of the winners in the Wheatley Hills Sweepstakes and the Massapequa Sweepstakes were hardly taken notice of. Nevertheless, these cars, considering their limited cylinder capacity, achieved very high speeds, and what is more, there were proportionately fewer retirements among the contestants in these classes. Of the four cars competing for the Wheatley Hills Sweepstakes the Marmon was easily the

fastest, requiring about 12½ minutes to the lap, and as it ran with the regularity of clockwork it was an easy winner. The Columbia also ran well, but it required a shade less than 15 minutes to the lap. The Moon, No. 34, seemed to be the equal of the Columbia in speed, but it disappeared after completing six laps. The Marion spent considerable time in stops at the pits and completed only nine laps, although it was still running at the time the race was stopped.

For the Massapequa Sweepstakes there were six contestants, two Chalmers-Detroits, three Maxwells and one Hudson. All but the Maxwell, driven by Thomas Costello, and the Chalmers-Detroit, driven by B. Brown, finished this race. The event was won by Joe Matson, the Chalmers-Detroit driver, who won his first laurels in the Crown Point-Lowell race last June by winning the Indiana Trophy. His time for the ten laps was 2 hours 9 minutes 52 2-5 seconds. Matson drove a fine race from the time he was sent off by the starter to his crossing of the finish line. Second place was secured by Martin Doorley, driver of the 22 horse power Maxwell. No. 46, and third place by another Maxwell, No. 44, driven by Arthur See. The times of the two Maxwells were only about two minutes apart. The fourth car to finish in this race was the Hudson, No. 42, driven by George Ainsley, which made the excellent time of 2 hours 31 minutes 47 2-5 seconds.

The races were notable for the absence of all serious personal accidents, and the material damages to cars were also slight

Among the notable occupants of the grand stand were John D. Rockefeller and Sir Thomas Lipton.

Sharing in the honors of the race with the manufacturers of the winning cars are the Michelin Tire Company, of Milltown, N. J., whose tires were found on all of the winners, and the Bosch Magneto Company, of New York, with whose magnetos each of the three winning cars was equipped.

MARMON, WINNER OF WHEATLEY HILLS SWEEPSTAKES, AT WESTBURY.

#### ome Observations Along the Course.

point which was noticeable on the of the course outside of the Parkway he lack of large congregations of specat a given point. From the Hicksurn back almost to Central Park, the tors and the parked cars got thinner hinner, until the sight of a parked ot to be a rarity. Parking spaces d to almost go a-begging, some being for as low as one and two dollars. s were almost entirely absent. Even Hicksville turn, which was in the of the village and which was one sharpest on the course, the congesvas only moderate. At this point and Westbury turn the road was banked two to three feet high. However. of the drivers took these turns very vatively, so much so that the banking d entirely unnecessary. From the ville turn for about a half a mile along the back stretch or old country so called, the spectators and the d cars were fairly thick, but they ally thinned out from this point. One noticeable feature was the number of which were parked well back in the and on crossroads, where probably or no rent was charged.

side of the Parkway the congestion probably greatest from the intersecf the Merrick road with the course Westbury turn. At both these points ourse was well policed. This point ill as Hicksville was rounded with n by most of the drivers. At the on of the Merrick road and the course slight left and right jog at which of the drivers slowed up. From this to the turn there was a slight up of 2 or 3 per cent, which helped to he speed down. It was evident from ay that the crowd congregated that they wanted to see was the high made on the straights rather than e accidents at turns. During the p the machines showed a tendency bunched in the vicinity of the Hicksurn. In many cases two or three

machines would pass this point not more than fifty yards or so apart. Many of the spectators along this part of the course kept their score cards religiously, and without an exception these all agreed that Grant, in the Alco, was in the lead. On his second round, just before reaching the Hicksville turn, Knox, with his Atlas, stopped for some sort of engine trouble, probably dirty plugs, for as soon as this was fixed the engine started up readily and ran with great smoothness. This machine aroused considerable interest along the course and called forth much favorable comment on account of its performance, considering that it was comparatively untried. The sound of the motor was a continuous roar, and could readily be distinguished by most of the spectators before it came in sight. A comment which was freely heard along the course was that with a higher gear the performance would probably have been much better.

On his seventh round Grant, with his Alco, had a flat left rear tire at about the centre of the backstretch. This drew quite a crowd, as most everybody was interested to see a tire change made. The methods of carrying the tools very much facilitated

the change. The jack was carried in an upright position on the upper part of the footboard, the base being held in a Cshaped flat piece of metal attached to the horizontal part of the footboard, it being retained in position by a latch at the left hand. The mechanic had this in his hand ready to use before the car was brought to a standstill. While he was jacking up the wheel Grant took the brace from the footboard, where it was held in safety clips and used the same to expand the rim. As soon as he had the wheel jacked up the mechanic got a spare tire ready to replace the injured one. In the case of the Alco this was easy, as they were in a sort of a basket in the rear, without any straps to be unbuckled and buckled again. He then assisted in the removal of the old rim, and the replacement of the new rim on the wheel. While Grant was using the brace to contract the new rim on the wheel he replaced the injured tire in the carrier, removed and replaced the jack on the running board and was ready to start the motor. The whole operation did not take over a minute and a half. The steadiness of running and the consistency of the Alco were remarked upon by almost everybody. One noteworthy feature was that most of the spectators seemed to be pretty well informed about the details of the cars and discussed their performance with considerable intelligence; in fact, they looked on the technical side rather than the sporting side.

The Maxwell, No. 45, in the Massapequa Trophy race was out on its second round owing to loss of cooling water through a leaky water pipe. Lorimer's No. 9, Chalmers, just before entering the Parkway on its thirteenth round broke the retaining lugs which held the rear pair of cylinders to the crank case. The bolts between the two cylinders, on both sides, were pulled bodily out of the casing, and the webbing between the cranks was badly broken.

A rather curious accident happened to Columbia, No. 33. A small hole was made in the lower part of the rear crank case

MAXWELL No. 44 AT HICKSVILLE.

JOE MATSON (CHALMERS), WINNER OF THE MASSAPEQUA SWEEPSTAKES.

on the right hand side, and caused a loss of oil. Just how this was made is not quite certain, but it was thought that a stone was picked up by the flywheel, which was not protected by a dust pan, and worked in between the flywheel and crank case. The loss of oil was made good to a certain extent by the mechanic, who kept pumping constantly with his hand pump.

The Moon car broke its overhead cam shaft in two places between the second and third cylinders.

The Chalmers team had a score board about a quarter of a mile from the Meadowbrook entrance to the parkway, where the position on the last lap was announced by large numbers. This information was received direct from the grand stand by telephone. The number of the car was placed on top, then the lap, and below this the position. There were, of course, places for the announcement of four cars. The numbers were about 1 foot high.

A rather interesting detail was the fact that a large number of the cars were equipped with speedometers, which were used both in practice and in the race itself.

Among those in charge of the racing crews, Harry L. Bill, of the Chalmers-Detroit Motor Company and Arthur N. Jervis, of the American Locomotive Automobile Company, deserve particular mention for the efficient way in which they kept their respective drivers informed of their position in the race. Mr. Jervis also deserves credit for the effective manner in which he backed up his protest concerning the losing of one of Grant's laps by the scorers. At first the officials paid little attention to Mr. Jervis's complaint, but his persistence at last induced them to look into the matter, with the result that his efforts were rewarded, and Grant was declared the winner.

Among the prominent tradesmen noticed at the race by the representatives of The Horseless Age were the following: H. W. Chapin, W. S. Gorton, Benjamin Briscoe, Howard Marmon, C. M. Hall, Capt. Wm. Mitchell Lewis, Fred I. Tone, Elmer Apperson, Hugh Chalmers, Howard E. Coffin, H. W. Nuckols, Hauvette Michelin, J. C. Matlack, Horace De Lisser, Wm. E. Metz-

ger, A. C. Newby, L. J. Bergdoll, J. M. Gilbert, Harry Fosdick, N. E. Parish, Thos. J. Wetzel, D. J. Post, L. D. Rockwell, Thomas Miracle Forbes, E. R. Hollander,, A. G. Hoffman, E. V. Hartford and E. H. Broadwell.

At a meeting on Monday of the executive committee of the Motor Cups Holding Company, Mr. Vanderbilt, as referee of the event, reported that he had awarded the Vanderbilt Cup to the Alco, No. 8, driven by Harry F. Grant, and entered by the American Locomotive Company; the Wheatley Hills Trophy and \$1,000 cash to the Marmon car, No. 32, driven by R. W. Harroun, and entered by the Nordyke-Marmon Company; the Massapequa Trophy and \$1,000 cash to the Chalmers-Detroit "30." No. 43, driven by Joe Matson, and entered by the Chalmers-Detroit Motor Company. Mr. Vanderbilt further reported that the Fiat, No. 14, entered in Class I, was placed second, and that the Atlas, No. 5, and the Chalmers-Detroit "40" were still running when he declared the race off and that no award was made in Class 2. The referee further stated that a statement had been made and signed by the official timers and scorers to the effect that they had omitted to score one lap for the Alco, No. 8. Mr. Vanderbilt also reported that no protests had been filed.

A protest was lodged with the Motor Cups Holding Company following the publication of Mr. Vanderbilt's announcement, however, by the Atlas Motor Car Company, concerning the decision that no award should be made in Class 2 of the Vanderbilt Cup entries. The Atlas Company lay claim to first position in this class and to the award of the prize offered.

The following table gives the results of the four previous races for the Vanderbilt Cup, all of which were run on Long Island:

1904—Panhard (Heath), 302.4 miles; average speed, 52.2.

1905—Darracq (Hemery), 280.30 miles; average speed, 61.49.

1906—Darracq (Wagner), 290.70 miles; average speed, 61.43.

1908-Locomobile (Robertson), 258.06 miles; average speed, 64.38

#### Off for Atlanta.

A party of racing drivers in charge of Fred J. Wagner left New York over the Seaboard Air Line at midnight Wednesday for Atlanta, Ga. The party, which traveled in two special cars, comprises many of the drivers in the recent Vanderbilt Cup race. A. R. Pardington, second vice president and general manager of the Long Island Motor Parkway, will act as referee of the Atlanta races, and S. A. Miles and Alfred Reeves will act as judges. The Warner timing apparatus, in charge of C. H. Warner and A. J. Interrieden, will be used for timing.

# Manufacturers' Attitude Toward

In connection with the inquiry made by the Automobile Club of France among leading European manufacturers, as to whether they would take part in the Grand Prix race in 1910, it is learned that the firms of Panhard-Levassor, Renault, Brasier, Lorraine-Dietrich, Mercedes, Fiat, Napier, Peugeot, Berliet, Germain and Motobloc maintain an antagonistic attitude toward the race. Darracq suggests a convention of manufacturers and will abide by its decision. Benz will be guided by the decision of other German manufacturers, but has already engaged a number of well known drivers, including Hemery. The following firms are thought to be almost certain to take part in the race: France-De Dion-Bouton, Sizaire-Naudin, Delage, Gregoire, Cottin-Desgouttes, Rolland-Pillain, Corre-La Licorne, Rossel, Westinghouse and Lion-Peugeot; Italy-Spa; Austria-Laurin-Klement; Great Britain-Daimler and Vauxhall; Spain-Hispano-Suiza; United States-Simplex.

#### Butler to Succeed Hower (?).

It is generally understood that Chairman F. B. Hower of the A. A. A. contest committee will resign at the expiration of his present term, and that the officials of the association have been looking for a suitable successor. The name of Secretary S. M. Butler of the Automobile Club of America has been mentioned a number of times in connection with the position, and according to the latest reports Mr. Butler's appointment has been practically decided upon. This choice must be regarded as a very happy one. Mr. Butler has been managing the affairs of the Automobile Club of America since its organization, and has therefore had a great deal of experience in the line of work that falls within the province of the chairman of the A. A. A. contest committee. He is very popular in automobile circles in and around New York.

Plans are on foot for the manufacture of automobiles at the plant of the McGuire-Cummings Manufacturing Company in Paris, Ill. Cars are to be assembled from parts bought in the market.

#### The Phenomenon of Muffler Explosions.

BY ALBERT L. CLOUGH.

The complaint was recently made by the owner of a high grade, six cylinder car that it was very likely to explode most vehemently in the muffler, to the terror of all persons and horses within earshot, when the motor was started. A little inquiry elicited the fact that several other owners of six cylinder cars suffered rather frequently from this annoyance. Whether six cylinder cars are any more liable than fours to muffler explosions can hardly be stated with any kind of assurance, but there seems to be an impression current to that effect. The cars referred to above being all of the same make, it is not safe to draw any such conclusion from the data at hand.

#### A CASE OF IMMUNITY.

When one considers the subject one is likely to be rather surprised, not that these explosions sometimes occur, but that they do not occur oftener. The four cylinder motor on the car which the writer drives can be cranked over indefinitely, with the throttle say a quarter open and the spark cut off, and still there will be no muffler explosion when the ignition is immediately thereafter thrown on and the engine starts on the spark. One might think that the exhaust manifold, the exhaust pipe and the muffler would be filled with gas after such a procedure and that the first explosion in a cylinder would send a flame into the manifold and fire the gas therein. This does not happen, however, although the carburetor may be heavily flooded before cranking.

The same motor is habitually used as a brake for considerable periods when the car is running down hill, the throttle being set in the idling position and the spark shut off, but a muffler explosion has never taken place when the ignition was switched on, although one would expect the exhaust system to be completely filled with gas of the same quality that the engine "idles on" and on which it will even carry the car at a low speed on the level.

A number of times the experiment has been tried of opening the throttle wide while the engine was acting as a brake and then throwing on the magneto while the throttle was thus open, but no muffler explosion has resulted. This was tried with the ignition early and as late as the magneto afforded.

## CONDITIONS NECESSARY FOR A MUFFLER EXPLOSION.

It is pretty obvious that, in order to obtain an explosion in the exhaust system, the gas in the manifold must be in an explosive condition and that it should be reached by gas from the engine at a temperature above its point of inflammation. The richness of the gas entering the exhaust system when an engine is cranked is usually not very great, as the speed is low. Still it is rich enough to fire promptly in the cylinder which is within spark range,

although this cylinder is under only very light compression. Is the fact that the gas in the cylinder is slightly compressed, while that in the manifold is not, the determining factor?

It seems altogether more likely that the reason why no explosion occurs is that no flame passes the exhaust valwe of the cylinder which starts upon the spark, at the piston speed attained by the explosion which starts the motor, or even by cranking; the period between ignition and exhaust valve opening is probably long enough to cool down the burning charge below the temperature of ignition before it leaves the cylinder. The cylinder wall, furthermore, is in a cool condition.

It is not plain, however, why there is no muffler explosion in the case of a running engine with wide open throttle and the ignition suddenly switched on, as mentioned above. One would expect that flame would pass the exhaust valve and fire the gas promptly, and it is a fact that this actually occurs with many motors at times.

It is reasonable to suppose that a late spark, early exhaust release, hot cylinders and a rich mixture, or perhaps, one should say, a slow burning mixture, are conditions which favor these explosions.

Just what part, if any, the tightness of a muffler or its construction in general plays in this connection may be worthy of consideration.

#### AFTER STOPPING MOTOR.

When a motor is stopped by throwing off the switch, the throttle is generally opened quite widely and the motor usually makes quite a number of revolutions before it stops. This must leave the exhaust system full of unburnt gas. A gasoline mixture is somewhat more dense than air at the same temperature, and the muffler is usually lower than the exhaust manifold. Is there, on this account, a tendency for pure air to replace the gas in the system by a sort of "hydrostatic action," assisted by the ordinary effects of diffusion? If this is the case, does the exhaust system become purged of gas or the richness of the mixture become greatly reduced after it has been stopped for some time? In the case of the six cylinder car referred to in the beginning of this article muffler explosions have occurred after the motor has been still for quite a few minutes when the motor was "sparked" up. This particular car and others of the same make are not very economical of gasoline and seem to operate with rather rich mixtures.

There is a difference in the action of a four and six cylinder motor which may have some bearing upon their relative liability to muffler explosions.

#### IN FOUR CYLINDER MOTORS.

When a four cylinder motor is "sparked up" the exhaust valve of the cylinder which should have fired just before the one which starts the motor is open and has been open during the time that the motor has been at rest. The explosive charge in its cylinder has thus escaped to the exhaust manifold and may have been diluted by the process above spoken of. The exhaust valves of the other two cylinders are closed at the time of the opening of the exhaust of the firing cylinder.

#### IN SIX CYLINDER MOTORS.

With the six, the conditions are somewhat different, as two, cylinders are at times performing their corresponding strokes of the cycle simultaneously. Two cylinders are thus upon the firing stroke at the same time during four periods, which aggregate about one-third of the entire cycle. A motor of this type, although it may stop at almost any portion of the cycle, when the switch is thrown off, is pretty likely to come to rest during one of the six periods in the cycle when but one cylinder is performing compression. At such a point two cylinders are on the working stroke, the first cylinder in firing order being pretty well down on this stroke and the second cylinder in firing order being in the earlier portion of its working stroke. If the spark is set somewhat late it will be too late to fire the first of these two cylinders, but is likely to "catch" the second one and ignite it. Very shortly after this second cylinder explodes and before it has finished its stroke the exhaust of the first cylinder opens and discharges its unburnt charge into the manifold. While it is still doing so the exhaust of the cylinder which is firing opens, and, if the temperafure of the issuing gases is sufficient, the fresh charge from the first cylinder, possibly under a little pressure, may be ignited and its explosion may detonate the gases in the muffler even if they are rather too poor for ordinary ignition to effect their combustion. The same conditions prevail when the car is cranked. The cylinder which should have fired just before the one which actually fires first pours its charge into the manifold during and after the power stroke of the firing cylinder and is discharging unburnt gas when the exhaust at the firing cylinder opens.

Whether this difference in the action of the two types of motor renders the six more liable to muffler explosions is a "conundrum." It may be that this entire matter of muffler explosions is a simpler one than it has been made to appear here, and they are caused by "choked up" mufflers, an excessive richness of the charge at stopping, by unduly delayed combustion in the starting cylinder and similar causes. It is a fact that some chauffeurs leave their cut-outs open when about to start in order to avoid them.

This remedy is, however, productive of nearly as much noise as the phenomenon it is intended to avert.

About 60 miles of good roads have been built in Michigan since July 1 by forty-six counties.

#### International Road Traffic Agreement.

The International Road Traffic Convenvention, in Paris, completed its labors on October 11, the last session being attended by the French Minister of Public Works. Millerand, who in a brief address complimented the delegates and the Governments they represented on the results achieved. The following agreement was made, which was immediately signed by the representatives of France, Germany, Italy, Belgium, Bulgaria, Servia, Roumania, Montenegro and Monaco. The other delegates are obliged to report to their respective Governments.

#### I. CONSTRUCTION OF CARS.

Every automobile in order to be admitted in international traffic on public roads must either have been found suitable for the purpose in a test by the competent authorities or belong to a type which has been admitted in a similar manner. The trial must bear especially on the following points:

- I. The mechanism must be perfectly reliable and so arranged as to minimize the danger of fire or explosion, that saddle horses or driving horses may not be scared by the noises produced, and that the cars will not constitute the least danger to other traffic, nor seriously inconvenience pedestrians by the emission of smoke or steam.
- 2. The automobile must be equipped with the following devices:
  - a. With a reliable steering gear, permitting of steering the car easily and safely.
  - b. With two independent and sufficiently powerful brakes of which at least one is capable of being applied very quickly, and operates directly on the wheels or on brake drums directly secured to the latter.
  - c. With a device which even on heavy grades prevents all backward motion, if one of the brake systems should fail.

Every car weighing, empty, more than 350 kg. (7,770 pounds) must be provided with a reversing gear which can be put into action from the driver's seat.

- 3. The control devices must be so arranged that the driver can manipulate them with certainty without being obliged to take his eyes off the road ahead.
- 4. Every car must be provided with a name plate containing the name of the firm which manufactured the car, the serial number of the chassis, the horse power of the motor, or the number and bore of the cylinders, and the weight of the vehicle, empty.

#### II. REQUIREMENTS MADE OF DRIVERS.

The driver of an automobile must possess those qualifications which are a sufficient guarantee for the safety of the public. As far as international traffic is concerned, nobody can drive an automobile who has not first procured from the competent authorities, or from the authorized associations, after an inquiry as to his

competency, a certificate or driver's permit. Such a permit cannot be issued to persons under eighteen years of age.

#### III. DEPOSITION AND RECOGNITION OF INTERNA-TIONAL ROAD CERTIFICATES.

In international traffic, in order to give proof that the requirements made in Sections I and II have been met, international roads certificates will be issued according to a plan attached to the present agreement. The recognition of these international road certificates can be refused (1) when it is obvious that the conditions under which they were issued do not correspond to the principles of Sections I and II; (2) if the owner or the driver of the automobile does not belong to any of the nations subscribing to this agreement.

## IV. METHOD OF CARRYING REGISTRATION NUMBERS ON CARS.

No car will be permitted to pass from one country into another which does not carry at the rear, plainly visible, in addition to its national number tag, a distinguishing tag with a letter designating its nationality. The form of this tag and of the number, as well as their size, will be defined in a table attached to the present agreement.

#### V. SIGNALING DEVICES.

Every automobile must be equipped with a deep toned horn for the production of warning signals. Outside of built-up districts it is permissible to make use of other warning signals which are in accordance with the regulations and customs of the respective countries. Every automobile must be equipped after dark with two forward lamps and one rear lamp, which latter illuminates the marks on the tags. The road ahead must be illuminated for a sufficient distance, but the use of glaring headlights in cities is prohibited.

#### VI. MOTORCYCLES AND MOTOR BICYCLES.

The provisions of the present agreement are applicable to motorcycles, bicycles and tricycles, with the following exceptions:
(1) The device which according to paragraph 2 of Section I, under letter c, is to prevent backward motion, is not required, nor is a reverse gear obligatory; (2) only one lamp is required, which must be carried in front; (3) the nationality tag needs only be 18 cm. wide and 12 cm. high (7.2x4.8 inches); the letters must be 8 cm. (3.2 inch) high, with a 10 mm. (3% inch) stroke; (4) the horn of motorcycles must produce a high note.

VII. PASSING AND OVERTAKING OF VEHICLES.

In passing and overtaking other vehicles, drivers of automobiles must strictly comply with the local regulations of the district in which they are driving.

#### VIII. ERECTION OF ROAD SIGNS.

Every one of the contracting states agrees to see to it as far as possible that for the purpose of giving warning of dangerous places along the roads, only those warning

signs which are attached to the present agreement are used. It is not excluded, however, that through mutual arrangement of the Governments interested in the agreement, changes may be made in this system of road signs. There should be added to this system of signs a sign designating customs offices and the stop required at these, as well as a sign for road toll stations and octroi stations. The Governments in addition must enforce the observation of the following principles: (1) In general it is not necessary to demarcate road obstructions inside of built-up districts by warning signs; (2) the road signs must be erected about 250 meters ahead of the road obstruction, unless local conditions do not admit of this. If the distance of the sign from the obstruction differs considerably from 250 meters, special arrangements must be made. (3) The road signs must be erected vertically to the road.

#### IX. GENERAL REQUIREMENTS.

The driver of an automobile in any country is obliged to comply with the laws and regulations concerning traffic on public roads in force in that country. An extract of the laws and regulations can be issued to the motorist upon his entrance into a country through the bureau at which the customs formalities are attended to.

#### SUPPLEMENT C.

The nationality tag must consist of an oval shield 30 cm. wide and 18 cm. high (12x7.2 inches), bearing one or two letters in black script, on a white background. These letters must be capitals in Latin script. They must be at least 10 cm. high and possess a width of stroke of 15 mm. The distinguishing letters for the different countries are as follows:

Holland, N. L. France, F. United States, U. S. Portugal, P. Great Britain, G. B. Russia, R. Roumania, RM. Germany, D. Austria, A. Greece, GR. Sweden, S. Italy, I. Spain, E. Switzerland, C. H. Belgium, B. Montenegro, M. N. Monaco, M. C. Hungary, H.

#### To Write Auto Insurance Only.

The Automobile Insurance Company of America has been organized in Indianapolis, with an authorized capital of \$1,000,000 to write automobile insurance exclusively. D. M. Parry, president of the Parry Automobile Company of Indianapolis, is president, and L. M. Littauer, a former member of Congress from New York, is vice president. This is the first company organized for underwriting automobiles exclusively.

At the annual show of the Tristate Vehicle and Implement Dealers' Association, which opened in the Armory Building in Cincinnati, Ohio, on October 25, there were nearly as many automobiles exhibited as carriages. It was explained that many carriage makers are going into the automobile business.

# New Vehicles & Parts

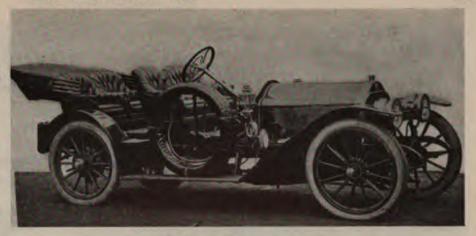

#### The Studebaker-Garford "Forty."

There are several minor changes in the Studebaker-Garford Model G-7 for 1910. The chassis is made at the Garford Company's plant at Elyria, Ohio, and the bodies and equipment are made by the Studebaker Company, of South Bend, Ind. The principal changes are as follows: The fan is mounted on an independent bracket instead of a bracket cast integral with the crank case. The universal joints on the propeller shaft are made larger, with greater wearing surface. The gear case is of entirely new design, of different shape from last year's case, and has the speed lever mounted on top of it. The sliding gear selective type of change gear is retained, however, and another speed forward has been added.

The muffler cut-out, which was formerly on the toe board, is now located on the heel board, and the floor boards, which were formerly aluminum castings, now consist of wood boards mounted in aluminum castings.

The motor is a four cylinder, four cycle and water cooled one, of 434 inches bore and 51/4 inches stroke. The cylinders are gray iron castings and cast in pairs, with intake and exhaust valves on opposite sides. They are carefully bored, reamed, ground and then lapped with clear oil with the pistons and rings in place. The water jackets are spacious, allowing free water circulation throughout. These jackets taper so that the greatest amount of water is at the top, where the temperature is the highest. The large openings over the water jacket provide for a careful inspection, and a certain removal of core sand, and are covered with aluminum plates. The small openings at the ends allow easy cleaning of the water jacket at any time, and are covered by cast iron plates.

The pistons are of the same material as the cylinders and are long, with four ec-

THE STUDEBAKER-GARFORD MODEL G-7.

centric rings ground on three sides, with step joints. There are also three oil grooves below the piston pins to provide for thorough distribution of oil on the cylinder walls. The hollow piston pins are Its inches in outside diameter and 45% inches long.

The connecting rods are I section drop forgings of 50 point carbon steel. They are 111/2 inches long. The upper connecting rod bearing is bushed with tool steel, hardened and ground to size. This bearing is 11/8 inches diameter and 21/2 inches long. The lower end bearings have die cast bushings of white bronze; these are 134 inches in diameter and 3 fe inches long. The top of the connecting rod is milled out to quite an extent, to form a basin in which to catch oil from the splash to lubricate the pins. The top bearing, however, instead of being milled like the connecting rod, is drilled with several small oil holes, which, being staggered, do not take away any of the bearing surface of the bush. The valves are single piece, drop forgings of 50 point carbon steel. They are 23% inches in diameter with 7-16 inch stems, and 36 inch lift. The lower end of the stem is hardened to prevent rapid wear. It is slotted to receive a flat key. which retains the valve spring cup. The cup is counterbored and drops down over the key and holds the key in place.

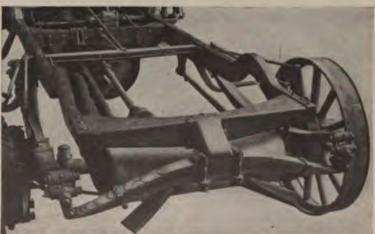

The valves are operated by valve lifters

of the roller type, these rollers being ground all over to size. The lifters work in brass guides and are provided with coiled springs to keep the roller continually pressed against the cam, thus preventing the possibility of slopping. The cams are of 20 point carbon steel, hardened and ground internally and externally. The external grinding is done with the aid of a master cam, so that every cam must be like every other. The cams are fitted to the cam shaft by means of keys and pins. The cam shaft is 3% inch diameter and of high carbon steel, hardened and ground, with three bearings, the two end bearings being 3 inches long and the centre 3th inches long. The cam shaft gears are of fibre and they mesh into the steel crank shaft pinion. The crank shaft is a 50 point carbon steel drop forging, hardened and ground. The main bearings are 118 inches in diameter and of various lengths, the front one being 35% inches long, the centre one 31/2 inches long, and the rear one 434 inches long. The extreme rear end acts as a pilot for the clutch. The crank shaft is provided with rings to catch the oil thrown from the ends of the bearings and carries it by centrifugal force to the hollow crank pin bearings. The flange to which the 17 inch cast iron, solid web flywheel is bolted is forged integral with the crank shaft.

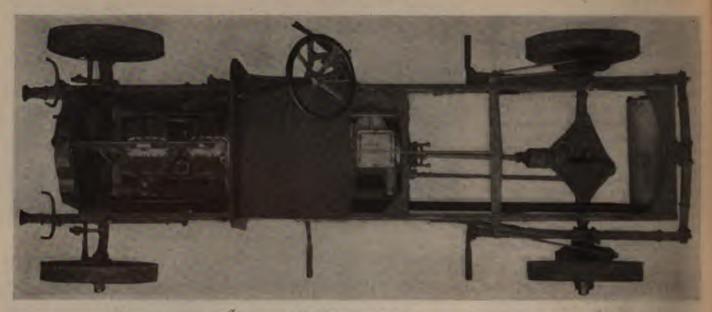

The crank case is an aluminum alloy

REAR VIEW OF CHASSIS SHOWING BRAKE AND PLATFORM SPRING.

PLAN VIEW OF CHASSIS.

casting in two separate pieces, the upper portion containing all the crank shaft bearings, of which the lower portion is entirely independent. The lower portion holds the oil for the splash lubrication and is supplied with oil by a gear driven Lavigne oiler with three main leads, one lead to each of the three crank shaft bearings. The lower case is provided with an oil drain cock, which governs the oil level.

The cam gears and magneto and pump shaft gear are all contained in an oil tight compartment at the front, and run in an oil bath.

Cooling is effected by a cellular radiator, a gear driven centrifugal pump and a ball bearing fan, driven by a 1 inch flat belt at 2½ times the motor speed and mounted on a bracket secured to the top of the gear compartment. The top of the fan bracket is provided with an eccentric for adjusting the tension of the belt.

The carburetor is of float and needle type and embraces the Venturi tube principle. It is located on the left hand side of the motor, midway between the cylinders, and connects to the inlet chambers by means of a Y shaped copper manifold of liberal diameter.

Ignition is by means of Bosch magneto and magnetic spark plugs.

The cone clutch is carried on the end of the crank shaft on a bronze bearing. It is 14% inches in diameter, with eighteen cork inserts and seven flat springs, to insure smooth action. The end thrust of the clutch spring is carried on a ball thrust and the clutch release collar is provided with a ball thrust bearing of large diameter. Between the clutch and the change gear is a double universal joint of block and trunnion type enclosed in a grease tight hardened and ground square sleeve.

The change gear is four forward speed and reverse selective type, with the gear lever working in an H slot quadrant. The direct drive is obtained on the third speed,

and the fourth speed is geared up. The transmission shafts are carried on annular ball bearings, and the forward end of the direct drive shaft is carried on an annular ball bearing in the direct drive gear. The gear case is barrel shaped, with an end plate at the rear end, the front end being solid, except where the bearings are inserted. The direct driving gear is mounted on two annular ball bearings. The propeller shaft is provided with a Cardan and cross universal joint back of the gear case, and a block and trunnion universal joint at the rear axle. These joints are all provided with pressure grease cups for lubrication. The drive bevel pinion is provided with annular ball bearings on both sides. The rear axle is of the full floating type, with the differential, which is of bevel pinion design, carried on cup and cone adjustable ball bearings. The wheel drive clutch plates are pressed on to the squared ends of the inner axle. The car load is carried on the heavy tubular axle housings. The spring pads are provided with a bearing and a grease cup, so that the axle may work without torsional strains on the springs.

The rear axle or bevel gear casing is a malleable iron casting, and is provided with a large cover, so that the differential can be removed without jacking up the car. Radius rods from the rear axle to the frame carry all the driving strains, while a pressed steel torque rod, supported on spring cushions, takes the torque strains. The rear wheels ride on cup and cone adjustable ball bearings.

The front axle is a one piece drop forging, with spring pads forged integral. The steering knuckles are carried on ball thrust bearings, with pressure grease cups at the top of the pivot bolts. The wheel spindles are fitted with cup and cone ball bearings.

The steering gear consists of a worm and gear, with ball thrust bearings above and below the worm. The worm gear is carried in eccentric phosphor bronze bearings which allow of adjustment. The 18 inch steering wheel is of mahogany fitted on a solid rim bronze spider. The spark and throttle control levers are located on a stationary quadrant above the steering wheel. The steering reach rod has ball and socket joints at both ends, which are fitted with spring cushions on both sides of the ball. The speed control and brake levers are drop forgings, and supported by a manganese bronze bracket.

The brakes are external contracting and internal expanding. The internal brake shoes are fitted with cork inserts. After the brake shoes are assembled they are ground concentric with the rear axle spindles to obviate the possibility of dragging. The brakes work through bar equalizers, and are operated by the usual pedal and hand lever.

The frame is of cold pressed nickel steel, of channel section, with a sub-frame on which are carried the motor and gear box. The frame, instead of being dropped, is arched over the rear axle to give a low suspension. The springs are semi-elliptic front and rear. The front springs are 40 inches long, 2½ inches wide and have seven leaves. The rear suspension consists of three point suspension platform springs. The side members are 50 inches long, 2½ inches wide and have nine leaves. The cross member is 36¾ inches long, 2¼ inches wide and has seven leaves. Every chassis is equipped with shock absorbers in front.

The gasoline tank is located underneath the front seat and holds 14 gallons. The wheel base is 118 inches. The standard equipment consists of two gas headlights two oil side lights, one oil tail light. Prest-O-Lite tank, robe rail, foot rest, tire irons, full set of tools, jack and tire repair kit.

Oscar Bergstrom, of Minneapolis, Minnahas invented and placed on the market a tire pump operated from the wheel hub. It is to be known as the "O-B" pump.

#### The De Dion Three Ton Truck.

This machine, which for the most part is built on standard lines, possesses some features which are characteristic of De Dion construction, but which are modified for the requirements of this paraticular class of work.

The wheel base is 146 inches and the tread 66 inches. The wheels are 32 inches in diameter, shod with solid rubber tires, twin tires being fitted in the rear. The chassis frame is of armored wood. The rear springs are semi-elliptic and the front springs three-quarter elliptic, insuring freedom from vibration of the motor and dri-

The change speed is a three speed and reverse selective, similar to the four speed used on their eight cylinder, 50 horse power car. The change speed lever works in a straight slot. The lubrication is by a geared oil pump within the gear case. The final drive is a slight modification of the regular De Dion construction employing Cardan driving axles. In this case the driving axles are connected to pinions which mesh with gears on the wheels, both the pinions and gears being enclosed in dustproof cases. This construction gives not only the necessary reduction of engine speed for the comparatively slower moving truck, but also al-

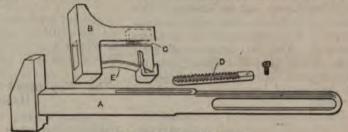

hand. The advantage of having one hand free while working with the wrench is ob-

In the accompanying cut, A is the bar which forms the handle and head; B, the jaw; C, the pawl, set into jaw; D, the rack which when the wrench is put together is set into the bar and held in place by set screw; E, the spring.

When the wrench is put together the jaw slides up and down on the bar, after being released by a slight pressure of the thumb on the back of jaw. When the jaw is adjusted to fit the nut the pressure is taken off the spring and immediately the

PARTS OF WRIGHT WRENCH.

ver's seat. The motor, which is located under the driver's seat, as is now well nigh universal practice in truck construction, follows the regular De Dion practice. It is a four cylinder of 25 horse power, fitted with magneto ignition. Both inlet and exhaust valves are mechanically operated. The carburetor is of De Dion make, and is of that type which employs a very small tube around the jet, thus forming a very rich mixture, which is afterward diluted by the air admitted through an auxiliary port of large size, controlled by an automatic valve. It is claimed for this type of carburetor that it is less likely to catch fire than the ordinary automatic type.

The clutch is their regular plate pattern.

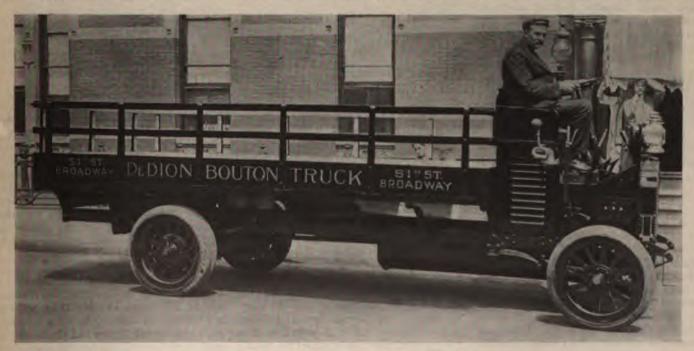

lows of much smaller driving axles than would the ordinary type of live rear axle.

# The Wright Wrench.

The Wright monkey wrench, manufactured by the Wright Wrench Manufacturing Company, of Canton, Ohio, while designed to do the work of the ordinary wrench is a radical departure from other wrenches in construction. It is made without a screw and is adjusted to fit the nut by means of a slight pressure upon the jaw with the thumb of the hand holding the wrench. It will thus be seen that but one hand is required to adjust and operate the wrench, leaving the other free for other purposes. It can be used equally well with either

pawl engages the rack, holding the jaw firmly in position. The pawl and rack each have a set of ratchet-like teeth which fit into each other and prevent the jaw from having any play after it is once set. The jaw is instantly released from the nut, however, by a slight pressure upon the spring. While the wrench is in use the spring has no strain upon it.

The Regal Automobile Company, of Detroit, have completed arrangements for the establishment of a \$100,000 plant in Windsor, Canada, to supply the Canadian trade. The plant will have a capacity for an output of five machines a day. Building operations will start in a week or two.

TWENTY-FIVE HORSE POWER DE DION TRUCK.

#### The Lansden Truck.

In order to reduce the ton-mile cost of goods transportation by motor wagon it is necessary to keep the trucks in operation as much of the time as possible during the working hours. This means, among other things, that the time taken for loading and unloading should be as little as possible, and any method which reduces this time is a means toward the desired end.

The Lansden Company, of Newark, N. J., realizing this point, have designed and manufactured a four wheeled electrically propelled truck for the purpose of transporting goods from one point to another in large warehouses and on wharves. This was specially built for the service, and was adapted to turn practically on its own centre as a pivot. They have lately brought out a three wheeler of smaller capacity than the four, designed for similar use, and also for the handling of baggage in large railroad terminals.

The maximum speed of the machine (4½ miles per hour) is purposely made very low. The mileage is about 18 per charge. This means about four hours of continuous running, but owing to the fact that the battery may be partially recharged while the truck is being loaded and unloaded at various points, and also to the fact that it, of course, is not in continuous use all the time, it can be run through an ordinary working day on one charge. The wheels are made small, the drivers being 24x6 inch, with solid rubber tires, and the steering wheel being of cast steel, 18x6 inches. The wheel base is 5 feet and the tread 52 inches.

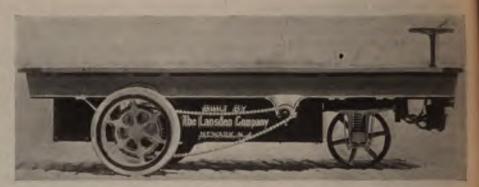

The platform load carrying space is 10x4 feet. The height from the ground to the platform is only 28 inches, which permits of easy loading and unloading. These machines have already been successfully used for baggage trucks in depots, as well as for dock work. Another field of usefulness would be as a substitute for industrial railways in large manufacturing plants, mills, etc.

# The Eureka Self Closing Nozzle.

The accompanying cut represents the Eureka self closing nozzle, handled by Geo. Grosselfinger, 192 Front street, New York. This nozzle is designed for garages, livery stables, and in fact anywhere that large quantities of water are used. When this

nozzle is used there is no waste of water while turning on or off at the end of a 25 or a 50 foot leugth of hose. It is so constructed that the valve closes when released or when the hose is dropped. Water is turned on and shut off by the closing and opening of the hand. This nozzle is rubber covered and has a flexible rubber tip for spraying purposes. Consequently, the high-

LANSDEN DOCK TRUCK.

ly polished surface of the automobile will not be scratched or damaged by coming in contact with the same. It is made in three-quarter and I inch sizes.

# The "Keystone" Safety Starting Handle.

A safety starting crank, which, it is claimed, cannot rotate backward more than a few degrees if the engine backfires, has been brought out by the Keystone Starting Handle Company, of Philadelphia, Pa. The ordinary form of this device contains three essential parts. A central portion I is

THE KEYSTONE SAFETY STARTING HANDLE.

rigidly fastened to the car, and provided with a ball race or notches in which a pawl may engage; an outer portion 2 is free to turn forward, but a pawl, ball or roller 3, ordinarily idle, serves to lock it to part I against reverse rotation. On part 2 is a cam A, shown in the cut, which ordinarily is carried along with the handle when cranking. In case of a backfire, however, the cam, being a portion of part 2, cannot rotate backward. The handle starts to turn backward, bearing against the edge of the cam, which is so shaped that handle and starting shaft are forced ahead and the clutch between the engine and handle shafts is thus disengaged. Under ordinary conditions when the engine is started this cam does not interfere in any way and the handle is thrown out as usual.

A second form, brought out for use where it is not desirable to have the starting handle bear directly against the cam, is made in four parts. A central portion I is attached to or made part of the handle shaft, and is provided with a ball race or notches; a second portion surrounds the

first and is limited to slight rotation. A pawl, ball or similar piece 3 unites the first two parts in such a way as to permit forward rotation, but to lock them if the handle starts backward. In the latter case a cam on part 2, which bears against a fixed projection 4 on the car, is so shaped that in a few degrees rotation it is forced ahead, carrying with it the starting handle and shaft and disconnecting them from the engine shaft.

## Two Clark Models.

The Clark Motor Car Company, of Shelbyville, Ind., are at present putting through two series of cars, one a 30 horse power touring car, to sell at \$1,400, and the other a 40 horse power touring car, to sell at \$1,750. The 30 horse power car is equipped with a 4x4 inch Rutenber motor, 34 inch wheels and 31/2 inch tires. It has a wheel base of 110 inches. The equipment includes five lamps, a Prest-O-Lite tank and a Remy magneto. The 40 horse power car is equipped with a 41/2x5 inch motor and has 34 inch wheels, with 4 inch tires. The wheel base is 118 inches. The equipment is the same as that of the 30 horse power. Both cars are fitted with five passenger bodies.

Meixell-Downing Company, 505 Odd Fellows Building, Indianapolis, Ind., are general sales agents for these cars. It is stated that deliveries will begin on December 15.

# The Continental "35," a New Car.

After considering a number of names, the Indiana Motor and Manufacuring Company have decided to name their car the Continental. The company was recently organized by Indianapolis men, and a factory has been established at Franklin. The product will be distributed by the Indiana Motor Sales Company, of Indianapolis, who inform us that they have placed an order for 1,000 Continental "35" cars for the season of 1910. It is a five passenger touring car, and will sell for \$1,400.

Frank D. Moon has secured a lease on a corner property at Lawrence and Clifton avenue, Edgewater, Ill. Mr. Moon will begin immediately the erection of a fireproof brick and cement factory and showroom, to cost about \$20,000. He expects to place on the market a business runabout and a light truck.

# What Makes For Hard and Easy Steering.

Editor Horseless Age:

If Mr. Sharples will take an ordinary bicycle and study its steering he will get some facts about steerings that will materially help him on the auto steering problem. A cycle wheel has the pivot or centre on which it turns in the plane of the wheel. The pivot line if extended will strike the ground directly ahead of the point of contact between the tire and ground. This is true of any caster, so the cycle wheel forms a caster and steers itself. If the line hits exactly as it should the cycle will easily be ridden hands off. But bend the forks to one side so as to throw the line to one side and the wheel will run to one side. But which side is the question. If the pivot is vertical, or nearly so, as in a caster, the wheel will run farther away from the straight ahead direction. But if the pivot has much rake to the rear at the top the wheel may run toward the straight ahead line. In auto wheels the pivot lines are usually nearly vertical, and they strike the ground inside the wheels. Disconnect the tie rod and the wheel will usually swing around to the rear and stand crosswise the line of motion. The tendency of one wheel to do this is balanced by the opposite tendency of the other one usually. So the trouble Mr. S. is having is not a matter of sidewise position of the pivots. If the pivots have some rake and point forward at the bottom, as does the cycle wheel, the vehicle will tend to steer itself, and will straighten up when power is being applied. Run the vehicle backwards and the erratic action of the steering will be at once apparent. In Mr. S.'s rig the pivots need to be raked forward at the bottom further. They probably strike the ground behind the point of wheel contact and the rig will steer better when running backward than when running forward. This condition may have been brought about / by running the rig against some curb or wall. In a cycle wheel the axle is much ahead of the steering pivot line, which shows the position of the axle has nothing to do with it. Some of the Stanley steamers were built with a very great rake and could run at speed with no danger of deflection. In fact, it took a strong pull on the lever to get them out of their course at speed.

In your able article on selling commercial vehicles at dull seasons of the year you overlook another rig that is in season when the usual pleasure vehicle is not. I refer to the motor buggy. This rig has hard tires and is usually air cooled, and so is not likely to give its user trouble in bad weather. It can stand up when the horse slips down on the ice, and is most needed when the

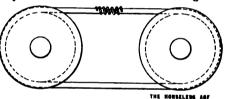

days are short and the busy doctor has not time enough to get around to his patients. It does not sell to the man who wants a conventional rig, but to a different class of buyers; and each buyer of a motor buggy will want a luxury rig some day, so it educates up to the better class of goods. It cuts into the horse carriage business, but helps the auto business. Many dealers turn up their noses at the idea, but they have some things yet to learn.

CHAS. E. DURYEA.

# Trouble from Belt Slipping. Editor Horseless Age:

The pumps in the mechanical oiler of my car are run by a round leather belt, with a section of about one-quarter inch diameter. running on two brass sheaves of about 4 inches diameter and I inch apart. I find great difficulty from this belt slipping owing to its stretching and absorption of oil, which it is impossible to keep away from it. I will be greatly obliged if you can advise me of any other kind of belting which would overcome this. Would a short, stiff spiral spring (as shown on sketch), substituted for the ordinary staple connection in the helt, answer, or is it possible to apply any dressing to the leather to prevent the loss of friction by the oil? BEGINNER.

[We do not believe that a short length of

coiled spring would be of much use in keeping the belt taut. Special piano wire coil belts are made for such purposes, and we would recommend that you get one of these, which can be obtained from any of the large supply stores. Usually these belts are about five-sixteenth inch in diameter, but you may be able to spread the flanges on the sheaves sufficiently to make the five-sixteenth inch belt keep on the sheaves.—Ep.]

# Magneto Ignition of Motors at Slow Speed.

Editor Horseless Age:

Referring to your recent editorial remarks on the insufficiencies of magnetos for motors when driving in dense street traffic on the high gear, your strictures cannot be held to apply generally.

The writer can vouch for it that there is one magneto at least on the market which will give a spark of full value when turning over only thirty-five times per minute. For a four cylinder motor the magneto speed is also that of the crank shaft, so that at only thirty-five revolutions per minute of the motor full ignition is had with this magneto.

Now 3 miles per hour is certainly a very slow speed in dense traffic or elsewhere; for 32 inch wheels that means thirty-two revolutions per minute of the rear axle. There are probably no cars in which the direct

reduction to the rear axle is less than 2 to I, which would give a magneto speed of sixty-four revolutions per minute, or much more than the thirty-five at which the Hess-Bright gives its full spark.

The writer has the best of reasons for knowing whereof he speaks; these reasons are most exhaustive, and long continued tests of day in and day out continuous running on the test stand, not only at this slow speed of thirty-five but also at the very trying higher speed of 3,300 revolutions per minute.

This slow speed coupled with an ability to retard the spark clear back, without changing its value from the maximum that is constant through a complete range of 55 degrees, is of value, not only for slow running but quite as much because it permits an easy cranking of the motor directly on the magneto, and without any complications by special mechanisms, and combines this with absolute safety while cranking.

These tests referred to, supplemented by the records of use by many builders of European automobiles, cabs and trucks, coupled with a constant spark for all positions of advance and retard, induced the writer to acquire the control of this magneto for this continent. Henry Hess, For the Hess-Bright Manufacturing Company.

[We would like to know what Mr. Hess means by "a spark of full value." He certainly cannot mean that his magneto will generate as large a spark at 35 r. p. m. as it will at any higher speed of revolution. Are we to understand that at 35 r. p. m. the magneto will generate a spark of sufficient volume to ignite a charge just at the limit of ignitibility; that is to say, a charge so poorly dosed and so much contaminated with spent gases that it is barely possible to ignite it by the most powerful spark?—Ep.]

# Auto Insurance in Mexico.

Editor Horseless Age:

Owing to the fact that there are no insurance companies in Mexico that will take risks on automobiles, we are writing to you with a view of obtaining information in this line.

Any information with which you may furnish us in the line of insurance companies in the United States that will take risks on automobiles in Mexico will be greatly appreciated.

McKie Walker.

[We have been in communication with practically all the companies represented in New York, and were informed that none of them write automobile insurance in Mexico, practically all confining themselves to the United States and Canada. It was suggested by one company that possibly the Lloyds of London would accept the risk, but their representative in this city could not confirm this, as all insurance matters are handled from London directly. We would therefore advise you to write to the company in London.—Ep.]

# Overcoming Need of Frequent Valve Grinding.

Editor Horseles Age:

Having noticed the article by W. R. Van Brunt, describing his troubles and the necessity of the frequent grinding of the valves of his car, let me say that Dr. Edward G. Acheson has run a Packard "30" fully 19,000 miles, and not a spark plug in it has been cleaned or a valve ground. This car has at times attained a surprising speed, indicating a large increase in power. Oildag is the lubricant used in the cylinders, and to this lubricant are attributed the results obtained. I may add this car is making 750 miles on a gallon of Oildag, whereas I believe the makers of the car advocate running such cars 150 to 200 miles on a gallon of oil. O E DUNLAP

## New Officials of American Federation of Motorcyclists.

Fred I. Willis, president of the Federation of American Motorcyclists, has announced the following appointments for the ensuing year: Membership committee: E. M. Estabrook, Bangor, Me., chairman; George W. Sherman, Chicago; W. F. Hapgood, Springfield, Mass.; F. B. Hart, Chicago, and W. F. Remppis, Reading, Pa. Competition committee: Dr. J. P. Thornley, New York City, chairman; Will Douglas, Louisville; F. L. Valient, New York City; J. S. Patterson, Chicago and Stephen Mc-Iver, Riverdale, Cal. President Willis is secretary and general manager of the Hearsey-Willis Company, automobile and motorcycle dealers, Indianapolis.

# Detroit Motor Club to Affiliate with A. A. A.

The newly organized Detroit Motor Club held a meeting in the Hotel Tuller on October 12, at which a resolution was passed to apply for admission to the A. A. A. through the Michigan State A. A. The proposed constitution and bylaws were provisionally adopted, and will be incorporated in a booklet to be published shortly. The club is carrying on negotiations with the Canadian Government for an arrangement by which members will be given visitors' privileges in Canada, and not be required to put up a bond. The club has its headquarters at the Hotel Tuller, and John Gillespie is secretary.

# Automobile Track Planned for Little Rock, Ark.

Announceemnt has been made at Little Rock, Ark., that Clinton Park, the local race track formerly operated by the Tilles-Celta Syndicate, will be remodeled for an automobile course. Little Rock capital is behind the project, and it is planned to hold a meet early in the spring.

The Interstate Auto Company, of Muncie, Ind., are building a 430x66 foot addition to their plant. The company expect to manufacture 2,500 cars in 1910.

# American Road Makers in Convention.

That all States should adopt the policy of giving State aid to counties in improving the highways of the country was the consensus of opinion of the 2,500 delegates who attended the good roads congress held in Columbus, Ohio, closing October 29 after a four days' session. Speakers representing the highway commissions of about a score of States, and delegates representing thirty-three States and Territories, attended the convention, which was probably the largest and most enthusiastic ever held in America.

One of the features of the meeting was the address of Samuel H. Hill, a relative of J. J. Hill, the railroad magnate, who attended from Seattle, Wash. Mr. Hill is one of the original good roads campaigners of the Pacific Coast. He advocated the employment of convicts in road building.

At the meeting of the Ohio Good Roads Federation a resolution was adopted favoring the Alsdorf bill, which provides for county aid, with perpetual maintenance by contractors. The congress voted to cooperate with the Daughters of the American Revolution in securing a boulevard from Yorktown to Jamestown, via Williamsburg.

Officers of the American Road Makers' Association were elected as follows: James H. MacDonald, Hartford, Conn., president; Samuel H. Hill, Seattle, Wash., vice president; E. L. Powers, New York, secretary, and Joseph W. Hunter, Harrisburg, Pa., treasurer. The executive committee will meet soon to decide the place for the 1910 convention. Columbus, Ohio, Omaha. Denver, Rochester and St. Louis are desirous of entertaining the association. James H. McDonald, Samuel H. Hill, E. L. Powers and A. C. Campbell were named delegates to represent the association at the international road congress to be held in Brussels in July.

# A. A. A. State and Club Membership.

In preparation for the annual meeting of the American Automobile Association. which will be held at the end of November, Secretary Frederick H. Elliott has been compiling a complete list of State associations and clubs affiliated with the National body. The growth in State associations during the past year has been particularly marked, there now being associations in thirty-one States, this including, however, the Hawaiian Association. In respect to membership the New York State Association leads with 4.518 members, the Pennsylvania Motor Federation coming next with 3,113, and the Associated Automobile Clubs of New Jersey, third, with 2,156. Six organizations have a membership of over 1,000-Minnesota, Ohio, southern California, Illinois, Massachusetts and Connecticut. Among the large number of clubs affiliated with the national body the latest statistics show that forty have a membership of over

100. The Automobile Club of Buffalo heads the list with 1,827 members, followed by the New Jersey Automobile and Motor Club with 1,274, while the Automobile Club of Philadelphia is just short of 1,000. The automobile clubs of Chicago, Minneapolis, Cleveland, Long Island and Rochester each have over 500.

# Circuit of Shows Planned for Central New York Cities.

The Binghamton (N. Y.) A. C. will hold an automobile show in the State Armory, February 21-26. A plan is on foot between the automobile clubs of Buffalo, Syracuse and Rochester, with the object of holding a circuit of shows in regular succession in the big cities of central New York, and inducing the leading firms in the industry to patronizz all of the shows. The Buffalo show will be held February 14 to 19. In Rochester a show will be held probably the first week in March, and in Syracuse the second week in March.

# E-M-F Canadian Company Organized.

The Everitt-Metzger-Flanders Company is organizing a subsidiary company, to be known as the E-M-F Company of Canada, for supplying the Canadian, British and British Colonial trade. The plant of the Globe Furniture Company in Walkerville has been purchased, and will be equipped for the manufacture of automobiles at once Among the stockholders of the Canadian company are Fredk. H. and J. Harrington Walker, of Hiram Walker & Sons Company, Walkerville. Both the E-M-F "30" and the Studebaker-Flanders "20" are to be manufactured in the Canadian plant.

# Packard Philadelphia Branch.

Packard cars will hereafter be sold in Philadelphia and surrounding territory by the Packard Motor Car Company, of Philadelphia, which has purchased the business of the Keystone Motor Car Company. The business will be conducted at the same store, 216 North Broad street. M. J. Budlong, who is president of the Packard Motor Car Company, of New York, is also president of the Packard Motor Car Company, of Philadelphia. Mr. Godshalk, who retires from the business on account of this purchase, was one of the earliest Packard dealers and introduced the Packard to Philadelphia in the season of 1904.

## General Motors Stock Dividend.

The General Motors Company has declared a stock dividend of 150 per cent. on its common stock, which will be payable November 5. The company recently increased its common stock from \$5,500,000 to \$40,000,000, and the stockifolders will therefore receive a portion of the newly issued stock. Since its organization about a year ago the company has paid a dividend of 7 per cent. on its preferred stock, but no cash dividend has yet been paid on the common stock.

# New York-Atlanta Good Roads Tour.

The New York Herald tourists started on the third day of their journey from Gettysburg at 7 o'clock last Wednesday morning, and traversed the southern section of Pennsylvania, crossed the narrow eastern creek of Maryland and the northeast corner of West Virginia, then dropping into the historic valley of Virginia. This was the longest day's run.

The contestants encountered roads of all sorts and conditions, and yet but one competing car was penalized for being behind the schedule, while another met with an accident which put it out of the contest, though luckily neither of the two passengers was seriously injured. In addition penalties were imposed on four contestants for yielation of road rules.

Near Middletown, Va., about 16 miles southeast of Winchester, where the noonday halt was made, the Oldsmobile, entered and driven by Frederick Weis, of Brooklyn, N. Y., in seeking to pass the Craig automobile, crowded close to the edge of the highway, and as it came abreast of the latter's machine Mr. Weis's car struck a big stone flanking a culvert at this point, causing it to skid violently against the Craig. One of the rear wheels on the Oldsmobile snapped off and the car was thrown into the ditch.

Though the bad roads encountered during the morning between Gettysburg and Winchester caused much tire trouble and tried the springs of every car, only one other contestant besides Mr. Weis suffered a penalty through belated arrival at Staunton, Va.

Thursday's run covered the 92 miles between Staunton and Roanoke. The start was made at 8 o'clock sharp. The route led through the historic city of Lexington. All but one of the thirty-five contesting cars rolled into Roanoke on schedule time, and not a single penalty was imposed. The car that failed to arrive within the allotted running time was the Thomas, entered by Mrs. F. De Giers, of New York city. This contestant had the misfortune to break a steering knuckle in the run from Gettysburg to Staunton. More than three hours was occupied by a village blacksmith in making a repair. A penalty of 636 points was im-

posed on this car, which already had 67 points against it.

Friday's run took the tourists from Roanoke to Winchester, N. C., a distance of nearly 126 miles. The start was made at 7 o'clock, as the course was over hills and across many fords. Thirty-two of the contesting cars arrived at Winston-Salem with clean scores, while four cars failed to arrive within the allotted time. One car had broken down near Stoneville, a village 43 miles from Winston-Salem. Another contestant, F. D. Hughes, of New York, driving a Chalmers-Detroit, wired that owing to illness he and his wife would spend the night in Martinsville, Va., where the noonday stop for lunch was made, and would join the party at Charlotte, N. C., where Saturday's run ended. The other entrants delayed in reaching Winston-Salem included Mr. and Mrs. F. J. De Giers, of New York city, who broke a steering knuckle on Wednesday; the Maxwell, entered by its makers, which was said to have broken an axle fording Big Chestnut Creek in Virginia with its muddy approaches, and the Franklin car, driven by George H. Storck, of Jacksonville, Fla.

At this stage of the tour the only cars actively in the contest bearing penalties were the Oldsmobile, entered by Henry J. Lamar, Jr., of Macon, Ga., which had 24 points against it, and the Maxwell, entered by the Maxwell-Briscoe Motor Company.

Saturday's run led to Charlotte, N. C., a distance of 137 miles, where the tourists rested over Sunday. Of the thirty-eight original contesting cars thirty-two checked out of Winston-Salem for Charlotte. Only one met with a serious mishap on the day's run, while another received a small penalty for lateness. On examining the official records it was found that twentynine of the entrants still had clean scores. Of the six cars that had dropped out, two had expressed an intention to continue to Atlanta. The Pope-Toledo, entered by the Chamber of Commerce of Lynchburg. Va., dropped out at Philadelphia, after the first day's run. The Oldsmobile, entered by Frederick Weis, of Brooklyn, N. Y., retired near Gettysburg. F. D. Hughes, driving a Chalmers-Detroit, wired Saturday that he must withdraw, owing to illness. Mr. and Mrs. F. J. De Giers, of New York city, wired that they had reached Salisbury, N. C., and would continue to the end. Joseph D. Boyd wired that be and the Maxwell would be in before the departure of the tourists on Monday.

A fire that broke out in the open air parking space in Charlotte came near to destroying the majority of the cars in the tour. The gasoline tank of the Selden car entered by Evelyn Harris, of Atlanta, had sprung a leak, and the fluid had spread over the planking on the ground, when a pedestrian lit a cigarette and threw the burning match into the gasoline area. There was a hurried call for the fire department, while willing hands pushed the blazing car away from its neighbors. The Selden car had to be rewired before proceeding on the tour.

On the Stearns car of Col. and Mrs. William L. Peel, of Atlanta, the steering gear broke just outside Roanoke on Friday morning. Temporary repairs were made, but another breakdown resulted near Salisbury, N. C. Dr. De Giers carried Mrs. Peel to Salisbury, while Colonel Peel and Mr. Tilt, with the aid of a blacksmith, repaired the damage, and telephoned later that they had reached Concord, N. C., 24 miles out of Charlotte.

On leaving Charlotte on Monday morning the procession headed for Greenville, S. C. Thirty-one contesting cars made the run without being penalized. Eleven miles out of Charlotte the cars were ferried over the Catawba River on a small floating barge propelled by the current and lashed by long ropes to a cable stretched across the stream. Only two cars could be carried at a time, and owing to the delay thus occasioned the contestants were not formally checked out until the further bank had been reached.

At this stage there was only one contestant in the run with a penalty against it, the Oldsmobile entered by Henry J. Lamar, Jr., which was penalized 24 points. Others who had suffered penalties, but still continued, dropped into the non-competing class. The Craig car, a non-contestant carrying supplies of the Ajax-Grieb Rubber Company, broke a steering knuckle near

THE BENZ CAR IN THE TOUR.

Kings Mountain, but the village blacksmith soon had it repaired.

Tuesday's run from Greenville to Commerce, a distance of 110 miles, brought several in the endurance run to grief. Twentysix entrants still retained their perfect scores, though accidents resulted in the penalization of two contesting cars that had previously escaped, while another withdrew, and the Jackson, driven by Jacques Futrelle, was so delayed that its withdrawal was expected. Near the village of Piedmont, 12 miles out of Greenville, the Jackson car bent its axle. A roadside blacksmith soon remedied the trouble, but later, 10 miles out of Anderson, S. C., in trying to avert a collision with a farmer's wagon, Mr. Futrelle ditched his car. He was pulled out by the Maxwell machine which became a non-contestant the day before. The strain was so great, however, that the "good Samaritan" sheared off its transmission shaft. The drivers of both cars expected to be in line for the start of the last day's run.

The White Star, built in Atlanta, withdrew from the contest at Anderson, the noon stopping place, owing to a twisted crank shaft. The disabled car was towed in by Mrs. Cuneo in the official car. The Knox, entered by W. A. Kelly, of New York city, broke a throttle lever rod and came in late, being penalized 148 points. The Studebaker, entered by the Board of Trade of Winston-Salem, N. C., snapped a rear wheel near Lavonia, S. C., but its passengers managed to repair it and reached Commerce with a penalty of only 27 points.

At the outskirts of Anderson, S. C., a banner conveyed the following information to the tourists: "Speed Limit 100 Miles per Hour. We Are Glad You Came, so Come Again."

Wednesday morning twenty-eight contesting cars checked out at Commerce, Ga., for Atlanta, 81 miles distant. Of these twenty-six finished with clean scores, and of the thirty-eight cars that left Herald square thirty-five safely reached the final destination on time. Only three cars were compelled to withdraw during the whole tour on account of accident. Of those who finished seven had formally withdrawn

from the endurance contest for the tour prizes, owing to delays which had resulted in heavy penalties. The following cars arrived at Atlanta still in the contest:

THE HORSELESS AGE.

No. 4 Thomas, No. 17 Thomas, No. 22 Oldsmobile, No. 23 Thomas, No. 30 Renault, No. 35 Matheson, No. 44 Benz, No. 54 Franklin, No. 48 White Steamer, No. 20 Premier, No. 25 Pennsylvania, No. 46 Oldsmobile, No. 52 Corbin, No. 39 Selden, No. 2 White, No. 7 White, No. 5 White, No. 10 Buick, No. 14 Studebaker, No. 16 Buick, No. 26 Maxwell, No. 43 Chalmers-Detroit, No. 28 Maxwell, No. 19 Studebaker, No. 31 Reo, No. 42 Regal, No. 28 Maxwell.

# Holding Pool for General Motors Stock Planned.

Holders of the preferred stock of the General Motors Company have received a circular signed by W. C. Durant, requesting them to co-operate in a plan to establish a holding pool for the control of the company's preferred stock for a period of fifteen months. In the letter it is explained that in comparison with other securities bearing the same interest (7 per cent.) this stock is selling at too low a price "for the reason that the market is now controlled by brokers acting entirely in their own interests and for their own personal gain." The stock now is around 881/2.

The letter continues: "I am very well satisfied that the real market value of this security cannot be established until the larger holders of this issue co-operate to the extent of having the offerings made through some regular and responsible channel, and with that in view I have arranged with a thoroughly reliable New York banking house to handle this business for us."

Dr. E. R. Campbell, of Flint, has the matter in charge and preferred stockholders are requested to make prompt return of an agreement that is enclosed with the letter. They are informed that this plan will at all times protect their interests, the sole object being a proper and comprehensive handling of offerings of stock, to insure the best possible returns for stockholders desiring to sell.

# Coming Events.

November 3-13-Salt Lake City, Utah, Outdoor

November 4-Tampa, Fla., Reliability Contest,

Tampa A. C.

November 6—Start of Los Angeles (Cal.)

Phoenix (Ariz.) Road Race, Maricopa A. C.

November 6-13—National Automobile Show, un-

der the auspices of the N. A. A. M., at Atlanta,

November 6-17-San Antonio, Tex., Race Meet, San Antonio A. C.

November 8-9-Savannah, Ga., Highway Reliahility Contest, Savannah A. C.

November 9-13-Atlanta, Ga., Track Races, Atlanta Automobile Association.

November 11-Phoenix, Ariz., Track Race Meet. Maricopa A. C.

November 14-17-San Antonio, Tex., Four Day

Track Race, San Antonio A. C. November 20-21-New Orleans, La., Two Day Track Race, New Orleans A. C.

November 22-Flag-to-Flag Reliability Run, from

Denver to City of Mexico.

November 25-Redlands, Cal., Hill Climb, Mile Hill Climb Association.

December 12-San Antonio, Tex., Annual Endurance Contest, San Antonio A. C.

December 25 to January 1-Columbus, Ohio, Automobile Show Auditorium,

December 29-30—Philadelphia (Pa.) Annual Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7-New York City An-

nual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

January 8-15—New York Annual Show, Madison Square Garden, Association of Licensed Association

tomobile Manufacturers. January 17-24-Philadelphia, Pa., Automobile

Show, Second Regiment Armory.

January 24-29—Detroit, Mich., Automobile Show,

Wayne Hotel Gardens.

February 4-6-New Orleans, La., Annual Mardi Gras Speed Carnival, New Orleans A. C.

February 5-12-Chicago, Ill., Ninth Annual National Show, Coliscum.

February 14-19—Buffalo, N. Y., Auton Show, Broadway Arsenal, A. C. of Buffalo. February 19-26-Newark, N. J., Automobile

Show, Essex Troop Armory. February 19-26—Salt Lake City, Utah, Antomobile Show, Auditorium.

February 21-26—Binghamton, N. Y., Automo-bile Show, State Armory. February 22-26—Kansas City, Mo., Fourth An-nual Show, Convention Hall, Kansas City Automo-

bile Dealers' Association.

Barney Oldfield has purchased from the Knox Automobile Company a six cylinder machine which he intends to drive in stock chassis events. He is making a circuit of the Western States.

TY COBB IN THE CHALMERS CAR.

35 HORSE POWER SELDEN CAR.

#### Motor Fire Apparatus in Small Towns.

BY W. V. WOEHLKE.

During the last two years three of the smaller towns of southern California have purchased and operated motor propelled fire apparatus, and, after a thorough test of the efficiency and cost of the apparatus, the experiments have proven that, for towns from 2,000 to 25,000 inhabitants at least, the self propelled apparatus is a success. The cost of maintenance, it was shown in all instances, was less than 75 per cent. of the expense caused by horse drawn apparatus. the radius of action was larger and the emciency, measured by the speed with which the motor apparatus would reach the scene of a fire, left the performance of the old style machines far in the rear. These results appertain only to combination chemical engines and hose wagons, however, no self propelled pump having seen service in the towns in question, though one of them, encouraged by the success of the chemicals, is preparing to add a pumping engine to its equipment.

For a year a combination chemical engine and hose wagon, with the usual equipment of ladders, axes, hose and tools, besides a carrying capacity of eight men, has been in operation in South Pasadena. The apparatus was built by a Los Angeles assembling firm on a stock chassis of 128 inches wheel base, with a four cylinder, water cooled motor, capable of driving the machine at 50 miles an hour. Before the purchase the town relied for its fire protection upon two hose carts pulled by the volunteer firemen. On long runs no team can keep up the pace set by the motor apparatus, though on short distance runs the advantage is not so apparent. During the year the cost of operation and maintenance has averaged \$8 per month. Included in this amount is the cost of gasoline and oil, of cleaning rags, polisher and two repair bills. No allowance has been made for depreciation. The apparatus is taken out by the driver every day, and averages about 125 miles per month.

In Hollywood, a town of about 4,000, near Los Angeles, the cost of operation and maintenance for a similar apparatus for two years has averaged \$4.63 per month. In cleaning the machinery, warming up the engine three times daily, and in testing the engine in daily runs averaging 60 miles per month, about 25 gallons of gasoline, costing \$3.85, were consumed, while the monthly gallon of oil averages 75 cents. Repairs have not been necessary except minor adjustments made by the driver.

Long Beach, a city of about 15,000, two years ago replaced two teams of horses by motor propelled combination hose wagons and chemicals, both of them built on tour-

ing car chasses. Owing to more and longer runs, the monthly cost for gasoline and oil has been slightly more than \$5 per apparatus, while tire expenses and repairs added about \$13 monthly, making a total cost per month of \$18 for each chemical. Long Beach used up a set of tires in two years, while the tires on the Hollywood apparatus seem to be good for another year after having served twenty-five months. In all of the four engines mentioned the tires are subjected to undue strains, owing to the faulty distribution of the weight. Since the wheel base of all the machines is comparatively short, the weight of the hose, the ladders, tools, chemical tanks and firemen rests mainly on the rear axle, while the front axle has to support but the weight of the motor and the driver and his assistant. By a lengthened wheel base and better load distribution the life of the tires could be increased.

Long Beach is the only town furnishing figures comparing the cost of maintaining and operating the two motor fire engines with the cost of the two teams formerly employed in doing the work. While the monthly cost per motor engine averaged approximately \$20, the teams made necessary an expenditure of \$31 per month each. For four horses the expenses in a year were \$758.80, divided as follows:

Depreciation and interest on the investment in both horses and motor apparatus are not included in the statement. The fire commissioners of the three towns all declare, however, that a charge of 15 per cent. on the original investment will cover depreciation, since the machines are well taken care of, inspected and tested for defects and weaknesses daily, and subjected to strenuous work but rarely. In consequence of the thorough test Long Beach intends to add a pump and a third combination motor to its equipment, while the town of Santa Monica is agitating for a bond issue of \$20,000 to replace its horse drawn apparatus with motor vehicles.

Conditions in southern California, however, are strongly in favor of the motor apparatus as against the teams. Feed, as seen by the statement, is exceptionally high, thus turning the balance of cost in favor of the motor. Though there are heavy grades to overcome, the motor apparatus is never hampered by snow drifts or icy surfaces, and even in rainy weather the oiled roads and streets of the smaller towns make possible high speed in responding to an alarm.

#### Commercial Notes.

The sheriff of Milwaukee County, Wis., is to have a new automobile, to cost \$4,000, under an appropriation just made by the Board of Supervisors. The car will be

equipped with an ambulance body, which has been sorely needed.

It is reported that Fire Chief Salter, of Omaha, Neb., intends to ask the city council to provide automobiles for himself and assistants.

T. J. Neville, Charleston, S. C., has started a "Seeing Charleston" automobile service. He is operating one car, which starts from the Charleston Hotel every day at 10 o'clock a. m. and 3 o'clock p. m.

The city of Milwaukee, Wis., has selected another Rambler for official use, the city engineer's office being given a Model 54, at \$2,500. Milwaukee now owns fifteen or more official cars, and has spent in 1909 alone the sum of \$30,000 for automobiles.

An automobile truck line for freight and passengers, to be operated on Saturdays and Sundays only, is the plan of County Clerk Henry Falk and Frank Day, a leading business man of West Bend, Wis. The line would run between West Bend and Hartford, Wis.

At the recent National Dairy Show in Milwaukee, a motor propelled milk wagon was exhibited, with a capacity for carrying 800 pounds over any kind of roads. The wagon is designed for carrying nine milk cans, and is said to be capable of a maximum speed of 30 miles per hour.

The Conrad Land and Water Company, of Conrad, Mont., who are using a twenty-two passenger motor bus in their land business, have fitted the car with flanges on the four wheels, so as to adapt it for use on railroad tracks. The experiment is said to have proven entirely satisfactory.

The Friendship Fire Company, of Phœnixville, Pa., has been supplied with a motor propelled combination wagon, which is to be housed in a new structure on High street. The combination wagon is of Knox make. It is equipped with chemical tanks, hose and ladders, and in addition will carry fourteen men. The car cost \$5,000.

Columbus, Ohio, will soon have a taxicab service if the promises of the Columbus Tax-I-Cab and Auto Livery, located at 37 South Scioto street, are carried out. It is announced that three taxis will be placed in service in a week and three more in less than a month. The taxicabs will consist of Stevens-Duryea chasses, with bodies manufactured by the Barndt-Johnson Company, of Columbus.

Barclay & Brandon, an undertaker's firm of Atlanta, Ga., have placed an order with Crane & Breed, of Cincinnati, for a motor propelled ambulance, equipped with a 30 horse power motor, and designed for a maximum speed of 30 miles per hour. A novel feature of the ambulance will be that it will not bear the name of its owners, but instead a series of name plates will be carried, including the list of all the hospitals in the city, and whenever a call is received to go to a certain hospital the name of that hospital will be displayed on both sides of the ambulance beneath the words Emergency Hospital.

#### Recent Decisions.

STATE ENGINEER CANNOT DEMAND DEPOSIT FOR USE OF ROADS.

Under New York Motor Vehicle law, prescribing the rate of speed, and Subdivision 6, authorizing local authorities to set aside for a given time a specified public highway for speed tests or races, and Section 12, authorizing the State Engineer to make such rules as are necessary for the protection of the highway, it was held that the State Engineer had no authority to make a rule requiring a deposit with the State Engineer and Surveyor of \$200 per mile for each mile of said road to be raced over for each day of said race. It was further held that the State Engineer could not revive the law which the Legislature had given the local authorities power to suspend, and which they had suspended. Where the local authorities gave their consent and imposed no conditions, there is nothing in the statute to show that the consent of the State Engineer and Surveyor had to be obtained before the race could be run, and he had no authority to exact a deposit.-Morrell vs. Skene, 64 Misc. 185.

VEHICLE HEIGHT LIMIT IN PARKS

Where a party drove a double-deck omnibus which exceeded the prescribed height by more than a foot, provided for by the ordinances and regulations of the public parks of New York, which prohibited the use of a vehicle measuring over 10 feet from the tread to the highest part, it was held that the regulation was reasonable and within the power of the Park Department, under the New York Revised Charter, to prohibit the same in the parks.—People vs. Shellenberg, 133 App. Div. 79.

CONFLICT OF EVIDENCE.

An automobilist was driving in a city at about 10 miles an hour and reached the junction of another street before another vehicle, after dark, and made the turn and collided with a horse and buggy. There was some conflict of evidence as to whether the auto kept to the right hand side of the intersection of the streets in making the turn, and whether or not plaintiff's buggy was in the proper place when the collision took place, and on this conflict of evidence the finding of the trial judge in favor of the plaintiff would not be disturbed.—Schoening vs. Young. Wash., 104 Pac. 132.

This was an action against the automobile owner for damages and judgment was for plaintiff.

# Joy Rider's License Suspended.

The Massachusetts Highway Commission has suspended the license of Alexander O. Anderson, a Boston chauffeur, for one month, as the result of a complaint made against Anderson by Thomas D. Claffin.

Mr. Claffin brought his car to a repair shop and gave explicit orders that it was not to be taken out of the shop for any purpose in his absence. Anderson put in the defence that he had the car out for a test, and that he did not know of the orders left by Mr. Claffin. The board did not see it that way, however, and issued the following opinion:

"The use of a motor car on a trip of 150 miles, mostly after dark, for the purpose of testing it, is not within the express or implied authority which can reasonably be attributed to persons intrusted with the repair of other persons' cars, and such a use is improper and unauthorized," was the comment made by the Highway Commission. Continuing further, the board explained its action as follows:

"The board imposes this light penalty because it is the first case of this kind which has come before it, and it realizes that many repair men and chauffeurs have thought that they had implied authority to use other persons' cars in this manner, but the board feels that this practice should be stopped, and that the testing of cars by repair men and others when the owner is not present should not be carried beyond reasonable limits, and that certainly a trip of 150 miles is far beyond a reasonable limit."

# Milwaukee Curb Standing Act Rescinded.

Automobiles may occupy Grand avenue and Wisconsin street, the main thorough-fares of Milwaukee, Wis., between the hours of 9 p. m. and 5 a. m., hereafter. The Milwaukee common council recently issued an order prohibiting any automobile from occupying any part of these streets longer than to let passengers alight or embark, but as traffic during the night is not heavy and the order caused much discomfort among theatregoers, taxicab operators and professional chauffeurs, it was deemed unwise to enforce the order during these hours.

Cushion Spring Patent Sustained.

The D'Arcy Spring Company, of Kalamazoo, Mich., have been granted an injunction against the Jackson Cushion Spring Company, of Jackson, Mich., restraining the latter from infringing Patent No. 785,410, owned by the D'Arcy Company. The injunction was issued by the United States Circuit Court for the Eastern District of Michigan, on October 6, 1909, after five years' litigation.

# Enforcement of Limited Non-Resident Exemption Clause Difficult.

Some apprehension is being felt in Pennsylvania as to the possibility of enforcing that section of the new law which goes into effect New Year's, which exempts non-resident motorists from registration in Pennsylvania, provided the home States grant similar privileges, for a period of ten days. The Highway Department, after securing legal advice, decided that all it can do is

to notify local authorities of the terms of the law, and leave its administration to them. How the local authorities are to determine whether a car has exceeded its period of grace is left an open question.

National Legislative Convention in Washington.

Charles Thaddeus Terry, chairman of the legislative board of the American Automobile Association, announced last week after a conference with the National Association officers that the first National Legislative Convention, under the auspices of the A. A. A., will be held in Washington during the middle of January. Plans are now under way to invite the Governors of all the States in the country, and in view of the increasing interest in the subject of good roads throughout the Southern and Far Western States it is believed that the delegations from these localities will be particularly large. It has been found that wherever the good roads subject becomes prominent it is at once followed by a demand for better laws regarding the use of the highways. The two chief matters that will be brought before the coming national convention will by the National Registration Motor Law and the Uniform State Law. The National Reg istration Act will be reintroduced into Congress by Congressman Cocks, who had charge of the bill last year, and it is proposed to secure a hearing upon the bill before the Judiciary Committee during the time of the convention in Washington.

## Legal Notes.

At a joint meeting of the St. Louis Automobile Dealers' and Manufacturers' Association and the A. C. of St. Louis on October 21 it was decided to jointly work for the adoption of the new traffic ordinance which was drafted by the club.

Attorncy General Byers of Iowa, in discussing his recent ruling that liability insurance for motorists is invalid in Iowa, states that motorists can get the same insurance as all other employers; that is, while they cannot insure themselves against liability for damages caused by their own recklessness, they can insure themselves against liability for damages caused by their chauffeurs.

## **Business Troubles.**

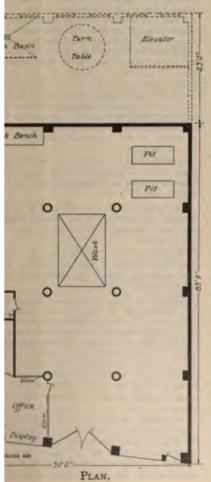

Suit for a receiver for the Auto Motor Company, of Cincinnati, Ohio, and for an accounting has been brought by William L. Divine, a stockholder. Complainant alleges that during the year ending January, 1908, the company did a business of \$100,000, but at a loss of \$8,000. Then a new board of directors and a new manager were appointed, and it was agreed, he alleges, that if at the end of six months the company was not being operated at a profit the manager should be replaced; nevertheless, although the company has ever since been conducted at a loss Reuben Payne has remained in charge.

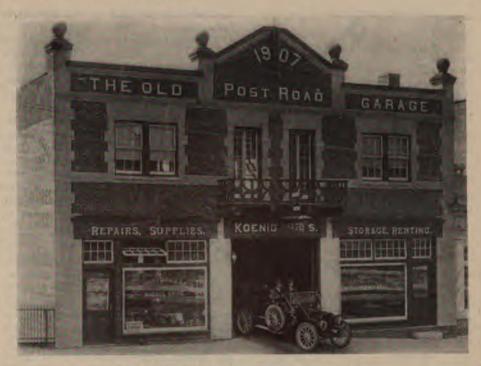

# Tarage Items

# Old Post Road Garage, Tarrytown, N. Y.

establishment, located on North lway, Tarrytown, N. Y., is one of the modern of the out of town garages s section of the country, and is cenlocated in that city, so that it is very nient for local patrons as well as for ts over the Old Post road leading New York to Albany. The cut shows scade of the building. The entrance ars is through large double swinging in the centre, and at either end are doors, the one at the left leading to airway to the second floor. The buildas two stories and basement, but at nt the second floor is unfinished. The is at the front, to the left of the en-, and is also used as a salesroom for es; it has a small display window deto accessories, and is very plain and esslike in its furnishings.

e building has brick walls and reind concrete floors and columns; it is 50 broad by 85 feet deep, but the propriepropose to make an addition to the 25 feet in depth, in the near future, it the same time increase the height by story. The windows at the front and car portion of the left side furnish am-

THE OLD POST ROAD GARAGE, TARRYTOWN, N. Y.

ple light during the day, and at night incandescent electric lights, liberally distributed, furnish ample illumination. The main floor is used principally for storage, and the two rows of columns shown in the floor plan divide this naturally into a central runway, with a storage space on either side. This floor will accommodate about thirty cars on storage, and in the basement about ten more can be taken care of. Very few cars are carried on dead storage, except in the winter. At the time of the writer's visit there were about thirteen cars on live storage, and two on dead storage, besides those in use.

The basement floor has an entrance for cars from another street, and about two-thirds of its space, at the rear, is devoted to repair work, and the remainder to storage. A steam heating plant is employed, there being wall coils near the floor around the entire main floor, and on the ceiling in the basement. The construction of the building being as nearly fireproof as can be imagined, the proprietors have not thought it necessary to install an elaborate fire alarm system, but a liberal supply of dry powder extinguishers and a few carbonic acid automatic extinguishers are distributed about the building.

Directly back from the office is a supply stock room, where a very complete line of tires and standard repair parts of all kinds is carried. A 1,000 gallon gasoline storage tank is located 4 feet below the basement floor, and is furnished with a Bowser pump for pumping the gasoline to where it is needed. Lubricating oil is kept in portable cans. Two grades, medium and light, are kept in stock.

At present there are two wash pits, one in the basement and one on the main floor, with overhead water connections. The repair shop in the basement is equipped for a variety of machine work. Power is supplied by a 5 horse power electric motor, and the tools include a 14 inch by 8 feet Flather tool room lathe, a No. 13 Garvin miller, an 18 inch Garvin drill press, a small Pratt & Whitney sensitive drill and two grinders. A small planer will soon be installed. A 4½x4½ inch Gardner air compressor with separate motor drive supplies inflating air through a 10 cubic feet storage tank. The proprietors make a specialty of tire repairs, and the equipment for this work includes a tube vulcanizer, a sectional vulcanizer and a steam cauldron, with a small vertical boiler

equipment for charging ignition batteries is provided.

No checking system has yet been used for supplies or gasoline, and the proprietors state that they realize that this is responsible for a very considerable loss. On repair work a duplicate check system is in use, and samples of the checks are shown herewith.

A considerable amount of renting business is done, three cars of the regular touring type having been used for this the past season. Provision is made for sending emergency repairs or supplies to customers who telephone in for the same. The Rambler cars are handled by the proprietors, Koenig Brothers, but no display cars are carried in stock.

# Brooklyn Dealers Plan to Organize.

Dealers of Brooklyn, N. Y., held an informal meeting for the purpose of organization at the Allen-Swan Company's establishment, at 1384 Bedford avenue, on October 27. A temporary organization was effected last year in order to give force to the dealers' opposition to the Long Island automobile show, then contemplated. The association has not been active since that time, but its officials presided at the meeting held last week, at which the proposal to make the organization permanent was discussed. A committee of three, consisting of C. M. Bishop, Lew H. Allen and I. C. Kirkham, was appointed to call on the regular dealers not attending the meeting and get them to join the organization. Another meeting is to be held at the same place in two weeks, when the organization will probably be completed and definite plans decided upon.

## Ohio Dealers Victims of Swindler.

William L. Offenbaugh and George W. Miller, proprietors of the Central Ohio Motor Car Company, of Columbus, Ohio, came close to being defrauded out of a motor car by a slick, paroled Mansfield Reformatory prisoner named James Fuller. Fuller represented himself as Jack Remington, son of wealthy parents, who desired to purchase a motor car. The proprietors defrayed his expenses to the factory at Pontiac, Mich., where a car was selected and a check tendered in return. Later, while attempting to purchase a diamond the identity of "Remington" was discovered. By quick work the car was kept from falling into Fuller's hands.

# Atlanta Garage Rates.

The garage owners of Atlanta. Ga., in anticipation of the coming show and track events there have reached an agreement with regard to rates to be charged for storage and supplies. The charge for storing a car for twenty-four hours is to be \$1.50; that for cleaning the machine \$1; gasoline is to be sold at the regular price of 15 cents per gallon, and oil and supplies are to be charged for at regular rates.

#### Garage Notes.

LAFAYETTE, O.—A concrete garage is being built for H. P. Maus.

GREENWICH, CONN.—A garage is being built on Campbell Smith's property.

PHILADELPHIA, PA.—F. A. Havens & Co. have filed plans for the erection of a garage on 48th and Chestnut streets.

ST. JOHNSBURY, VT.—Ground has been broken for the erection of a garage for C. H. Goss Company, on Central street.

NEW YORK, N. Y.—A new one-story garage is to be built for Engene Higgins at Nos. 182-184 West 230th street, to cost \$2,000.

West 120th street, to cost \$3,000.

TRENTON, N. J.—Harry J. Stout has bought the Central Garage, off East State street. He will handle the Pullman car exclusively.

PHILADELPHIA, PA.—Camille Gemehl has bought two garages at 1608-1610 Chancellor street from A. E. Borie for \$17,500.

PHILADELPHIA, PA.—Irwin & Leighton have obtained a permit for the construction of two large garages on Broad and Callowhill streets.

PHILADELPHIA, PA.—Work has been begun on a one-story garage for B. Ruckdeshel in the rear of 4034 Girard avenue, to cost \$5,000.

MANKATO, MINN.—D. D. Cummins & Ca, of South Front street, have moved their garage to W. H. Hammett's building on Walnut street. NEW BEDFORD, MASS.—Harold B. Grinnell,

NEW BEDFORD, MASS.—Harold B. Grinnell, 76 Cottage street, has applied for a permit to build a garage at the corner of Grove and Cottage streets.

MINNEAPOLIS, MINN.—E. W. Simpson has taken over the automobile repair shop and livery business located at Fourteenth street and Hempenin avenue.

PHILADELPHIA, PA.—Stearns & Castor have awarded the contract to the Wayne Construction Co. for a garage on Broad street, near Germantown avenue.

MINNEAPOLIS, MINN.—M. R. Waters & Son have obtained a lease on property at Laurel and Hennepin avenues on which they will erect an automobile building.

NEWARK, N. J.—The Square Garage Company of Brooklyn, N. Y., have opened a branch garage and repair shop at 489 Washington street, Newark, N. J. Ralph Blake is manager of the new branch.

CHICAGO, ILL.—The Anderson Carriage Company of Detroit have taken a fifteen years' lease on a two-story automobile building now in course of construction on Michigan avenue, north of a6th street. The front of the building will be of white enamel with green trimmings. It will cost \$40,000.

NEWARK, N. J.—Ground has been broken for the erection of a 70x130 feet pressed brick garage on Somerset and Barclay streets. Features of the new structure will be two large showrooms, a vacuum cleaning outfit, steam heat and all soders conveniences. Messrs. Paddock & Zuzi will secupy the new building, in addition to their present quarters on Clinton avenue.

SEATTLE, WASH.—The Couple-Gear Truck Co. are now located at 1927 First avenue South.

BALTIMORE, MD.—The Dixon C. Walker Auto Co. are having plans prepared for the erection of a garage at the southeast corner of Charles and 20th streets.

READING, PA.—H. F. Hoffer & Sons will conduct a garage and repair shop at 532 Cherry street in addition to their establishment at 126 South Tenth street and 422 Court street.

BOSTON, MASS.—The Regal Motor Company have taken possession of the salesrooms formerly occupied by the Auto Motor Company at 11 Park avenue. A. W. Mutty is sales manager.

avenue. A. W. Mutty is sales manager.
WILMINGTON, DEL.—A permit has been granted to C. R. Holt for the erection of a two-story 52x60 feet garage on Tatnall street, between 8th and 9th avenues. The estimated cost is \$6.000.

COLUMBUS, O.—The Maxwell-Briscoe Motor Company of North Tarrytown, N. Y., will open a garage at 62 East Spring street. The company intends to make Columbus one of its central distributing points.

tributing points.

BUFFALO, N. Y.—The Buffalo Auto Co.'s garage, at 1127 Main street, was damaged by fire on Oct. 20th to the extent of \$700. Spontaneous combustion in a pile of oil soaked waste is supposed to have been the cause.

ATHENS, GA.—Bishop & Flaton expect to occupy their new fireproof garage, now in course of construction on Washington street, about the first of the year. They will handle a full line of Maxwell, Pullman and Stoddard-Dayton cars.

INDIANAPOLIS, IND.—The Rambler agency in Indiana, which has been held by the Hearsey-Willis Co., has been taken over by the newly organized Rambler Auto Co., who are looking for a suitable location in the downtown district.

CHICAGO, ILL.—Plans are being prepared for the erection of a four-story building on the west side of Michigan avenue, south of 23d street, to cost \$100,000. The Baker Electric Vehicle Company will occupy the building after completion.

SEATTLE, WASH.—W. H. Heinzerling, formerly manager of the Fred A. Bennett Seattle branch, has bought out the latter's entire interest, and will locate at 1420 Broadway. He will handle the Renault, Reo, Great Smith and Rapid Commercial.

VINCENNES, IND.—J. F. Lanhan and B. T. Whitehouse have opened a permanent school of automobile engineering and instruction at the Wabash garage. J. F. Lanhan will give instruction in repair work, while B. T. Whitehouse will act as road instructor.

PHOENIX, ARIZ.—E. P. Stafford has severed his connection with the Central Auto garage and will establish a garage of his own at the corner of Second and Adam streets, in the building formerly occupied by Kunz Bros. He will conduct a general repair shop.

ALBANY. N. Y.—A garage is to be built for J. A. P. Ketchum, of Saratoga, on Washington avenue and Northern Boulevard. The plans call for a two-story building of marble and bronze, fronting 66 feet on Washington avenue, and 145 feet on the Northern Boulevard.

MARINETTE, WIS.—The Isham Motor Car Co. is the name of the reorganization of the Thayer-Isham Motor Co., agents for the Studebaker and Maxwell. Harry A. Thayer has withdrawn in order to enter business at Los Angeles, Cal., and O. R. Isham will continue the business.

SEATTLE, WASH.—The Woods Electric Vehicle Co. have entered the Seattle field, being represented by Carl J. Metzger, Jr., formerly sales manager for the Woods Company in Chicago. It is the intention of the Woods Co. to build a new brick garage in a fashionable residential section of Seattle, to be opened on or before January 15. I RUTLAND, VT.—The Rutland Garage Company are planning to build a three-story, 100x125 feet, reinforced concrete fireproof garage on the south side of Willow street. The first floor will be used for general storage purposes. The second floor, the entrance to which will be on Center

street, will have a large office, a show room, and a waiting room for patrons.

WILMINGTON, DEL.—Webb & Robinson are having a garage built on Railroad avenue.

WICHITA, KAN.—The Wichita Automobile Co. have purchased a 100 foot plot on the southeast corner of Lawrence and English avenues. HOUGHTON, MICH.—Plans are being drawn

for a new garage for the U. P. Motor Car Co., a branch of the Duluth Motor Car Co., Duluth, Minn.

WABASH, IND.—The Motor Inn Co., recently incorporated, will open a garage in the Mote Building. They have secured a five years' lease, and are remodeling the building.

CLEVELAND, OHIO.—Work has been begun on the Zimmerman Realty Company's garage on Euclid avenue and East Sixty-fifth street. The building is to be one story, 60x150 feet.

HOBART, OKLA.—D. A. Scott is president and general manager of the newly organized Scott Automobile Co., which will immediately erect a garage and conduct a general automobile agency and garage business.

WHEELING, W. VA.—E. J. Becker, who has severed his connection with the House & Becker garage, has joined forces with George Row, and will open a garage on Eleventh street, between Market and Main streets.

WALLA WALLA, WASH.—Mr. Hunt, of the Gilbert-Hunt Co., and B. C. Holt, of the Holt Manufacturing Co., both of Walla Walla, have tormed a copartnership for the purpose of handling the "Winton" Six in the northwestern part of Washington.

COLUMBUS, OHIO.—C. Roy Clough, manager of the Columbus (Ohio) branch of the Charles Schiaer Motor Car Co., has placed the following sub-agencies for the Hupmobile in Ohio: Wapakoneta, Hause & Bittle; Hamilton, Hamilton Motor Car Co.

CHICAGO, ILL.—A new automobile building, which when completed will be occupied by the agency for the Detroit electric car, is at present being erected on the local auto row. It will be two stories high, 45 feet wide and 190 feet deep, and have a façade of Florentine renaissance design.

FORT WORTH, TEX.—The Texas Motor Sales Co. will open a sales establishment here immediately after the Dallas Fair. They will handle the Cole "30" and the Marmon. H. E. Crowley is president of the company, Ira W. Word, of Senora, Tex., vice president, and J. O. Wright, of Dallas, secretary and treasurer.

DULUTH, MINN.—The Duluth Motor Car Co. have leased the ground for a new garage building to be erected this fall. The building will be two stories high, 50x140 feet, and will be complete in every detail, with chauffeurs' room and separate repair rooms for gasoline and electric cars. The location is on Superior street, and the estimated cost is \$30,000.

BOSTON, MASS.—Edward Paul, an automobile repair man, while taking a car up to one of the upper stories in the Motor Mart Building, inadvertently backed his car back into the elevator shaft, after having just left the elevator, and fell three stories, the car falling on top of him. Paul suffered numerous contusions and lacerations, besides a fracture of the left side of the skull, but it is thought that he will recover.

MARSHFIELD, WIS.—One of the largest garages in northern Wisconsin is now being constructed for Lang & Sherman, proprietors of the Marshfield Iron Works, recently appointed agents for the Maxwell. The garage will be 30x80 feet in size, with a capacity of twenty cars, the Maxwell order for 1910 delivery. The Iron Works manufactures the Paulson gasoline motor, and has produced several complete cars equipped with this motor.

OSHKOSH, WIS.—Zimmer & Malchow, who recently purchased the business of the automobile department of Gottfredson Brothers, wholesale hardware dealers at Green Bay, Wis., have organized under the style of the Green Bay Motor Car Co. The Gottfredson garage has been leased, and improvements are now being made which will make it 60x100 feet in size, with a repair shop of

21x44 feet. A large elevator will be installed in the building.

FLORAL PARK, L. I.—John Lewis Childs is building a concrete garage,

CAMBRIDGE, MASS.—The old Porter House is to be converted into a garage.

ELDORA, IA.—J. H. Hadley will soon erect a 50x120 foot cement garage and salesroom.

COLUMBUS, OHIO.—J. M. Hammil is having plans prepared for the construction of a garage in Bulitt Park.

SAGINAW, MICH.—The Buick Auto Supply & Garage Co., recently incorporated, have opened offices in the Bearinger Building.

BALTIMORE, MD.—The Motor Car Co. are preparing plans for improvements to their garage on Mount Royal and Maryland avenues.

HACKENSACK, N. J.—Charles Henderson is having a garage built on Prospect avenue and Golf place. The cost is estimated at \$8,000.

PITTSBURG, PA.—The William Zoller Co. have been granted a permit to build a one story brick garage in the rear of 346 Spring Garden avenue.

UNIONTOWN, PA.—The Tri-State Garage Co., newly organized, have leased the building formerly occupied by the Fayette Automobile Co. on Fayette street.

SAN ANGELO, TEX.—The Buick Auto Supply Co. will move from their present quarters in the Shubert Building to the Hatton & Riley Building this week.

LYNN, MASS.—Work has begun on the new Eastern Avenue Garage, next to Perkins' carriage factory. The structure is to be one story, 35x50 feet, with a concrete block front.

LYNN, MASS.—A garage is in course of erection for M. E. Sibley on land formerly owned by Henry O. Newhall. The building will be 71x101 and will contain a storage space and a repair shop.

WILMINGTON, DEL.—Clarence R. Holt, of East Fourth street, will conduct an automobile livery in addition to his hotel business. A garage to cost \$8,000 will be erected at 521 Tatnall street for the purpose.

GOSHEN, IND.—Teagarden & Putt have doubled their floor space by the addition of two more rooms. They will install a charging plant for electric machines. The north room will be used as a salesroom

TWIN FALLS, IDAHO.—T. W. Naylor, who has charge of the Boise (Idaho) branch of the Studebaker Brothers Automobile Co., has been in this city with a view to locating a branch here the coming winter.

the coming winter.

ALBANY, N. Y.—W. L. Schupp & Sons have let a contract for the erection of a two story brick addition to their garage on Bradford street. The lot is 43 feet wide on Bradford street by 52 feet deep. The plans provide for a driveway within the completed building from Bradford street to Central avenue. The first floor will be used for storing and cleaning, and the second will be equipped as a repair shop.

COLUMBUS, OHIO.—A. J. Pray, who has taken the agency for the Studebaker and E-M-F line in central and southern Ohio, and who has opened a salesroom on North Fourth street, Columbus, has closed sub-agencies as follows: Forsythe & MacElwane, Newark; Martens Hardware Co., Lancaster, and Turner & Rausch, Marysville. Forsythe & MacElwane, of Newark, are constructing a \$10,000 garage building on Tenth street in the rear of the Auditorium. They have now a temporary location, but are expected to occupy the new building about Christmes.

the new building about Christmas.

JAMESVILLE, WIS.—Robert Groshung was arrested here, charged with the theft of about \$100 worth of tires, spark plugs and other accessories from the Otto automobile supply store in Madison, Wis., which he sold to several Jamesville garages. The stolen goods are said to have been brought to Jamesville in an automobile by a man named Syke, and some of them are alleged to have been found in his room in the Y. M. C. A. Building, but Syke maintains that he was not aware how Groshung got possession of the goods.

The Midland Motor Company, Moline, Ill., have advanced the price of their Model L car from \$1.750 to \$1.800.

The new Atlanta (Ga.) branch store of Charles E. Miller is located at 66 Edgewood avenue, and was opened on November I. From this branch the Southern States are to be covered.

The Peru Auto Parts Company, Peru, Ind., a branch of the Salisbury Wheel Company, of Jamestown, N. Y., have secured a large order from the Overland Automobile Company, and will begin operations next month.

An addition has recently been made to the factory of the Woods Motor Vehicle Company in Chicago. Ill., which now has 160,000 square feet of floor space, and is claimed to be the largest factory devoted exclusively to the manufacture of electric vehicles.

The Sternberg Manufacturing Company, of Milwaukee, Wis., manufacturers of automobile trucks, will occupy its new factory, now under construction at West Allis, the manufacturing suburb, on May I. Contracts have been awarded for construction work. The plant will cost \$60,000.

According to a report from Chicago the loss ratio on automobile insurance is increasing, and the Lloyds of London, who have been holding aloof from entering into an agreement with the local companies regarding rates, are becoming disposed to cooperate with them in this matter.

The Lakewood Chemical Company, of Cleveland, Ohio, are manufacturing a preparation for removing the carbon deposits on combustion chamber walls and piston heads of automobile motors. S. W. Watterson, a member of the firm, is at present establishing agencies for the product in the East.

The Gibson Automobile Company, Indianapolis, has purchased the first automobile manufactured by the Premier Motor Manufacturing Company. It is a two cylinder, water cooled car, and was formerly owned by J. Edward Krause, an Indianapolis hotel man. The car has many of the features that are still retained in the Premier cars.

The vacation of certain streets and alleys asked for by the Toledo Motor Car Company (the Overland Automobile Company) has been conceded by the authorities of Toledo, Ohio. It is the intention of the Overland Company to erect additional buildings on these streets which run through the property of the company.

The Goodyear Tire and Rubber Company, of Akron, Ohio, have just closed with the Buick Motor Company, of Flint, Mich., what is considered to be the largest contract for tires that has ever been placed. The Goodyear quick detachable tire and rim will be the regular equipment on all Buick cars for 1910, and the contract covers the

entire complement of tires required for the whole 1910 Buick output.

The first car turned out by the Worth Motor Car Company, of Kankakee, Ill., a twelve passenger sightseeing vehicle, has just been completed and submitted to its initial road test.

The Studebaker Automobile Company are at present conducting a private 2,000 mile sealed bonnet endurance run in a Studebaker E-M-F 30 through Ohio and neighboring States, which will end in Cleveland.

From figures on collection of stable refuse in Milwaukee, Wis., the secretary of the health department estimates that 50 per cent. less horses are used in Milwaukee this year than in 1908. The advance of the automolife is given as the most likely reason.

The Bristol Engineering Corporation, of Bristol, Conn., which manufactured cars for several dealers as well as taxicabs, has passed out of existence, the business having been taken over by the parent concern, the New Departure Manufacturing Company.

The Court of Appeals of Atlanta, Ga., will not sit during automobile week, November 8 to 15, all cases set for that week having been postponed until a week later. The action is said to have been taken for the accommodation of the lawyers interested, who might have had difficulty in securing suitable hotel accommodations.

The Star Rubber Company, of Akron, Ohio, hitherto known chiefly as a producer of druggists' rubber sundries, will combine the manufacture of automobile tires and inner tubes with their present business. The company has increased its capital stock from \$100,000 to \$250,000, and is adding an additional three story factory building, the first two floors of which will be devoted to tire manufacture.

The first of the 500 new automobile freight cars of the Santa Fe railroad arrived in San Francisco on October 14 with a double decked load of automobiles, consisting of six large touring cars. The freight cars weigh 48,000 pounds empty, are 50 feet in length, 10 feet in height, and 9 feet in width. They have a steel roof support, a steel end door and diagonal side doors 10 feet wide and the height of the car.

The Indiana Motor Sales Company has been organized in Indianapolis for the purpose of handling the output of the Indiana Motor and Manufacturing Company, which was recently organized and has established a factory at Franklin, Ind. The distributing company is capitalized at \$10,000, and is composed of B. F. Meixell, Donald J. Hayden and C. O. Britton. Mr. Hayden is secretary of the automobile manufacturing company.

The Automobile Owners' Mutual Protective Association, of which James M. Pierce is president and W. H. Springer secretary, are seeking to amend the articles of incorporation, changing from Chapter 9, of the Iowa State Insurance Law to Chapter 7 of these laws. Chapter 9 covers the

field of liability insurance, and Chapter 7 that of accident insurance. The step was taken in consequence of the recent ruling of the Iowa Attorney General to the effect that liability insurance on automobiles is invalid in Iowa.

The Hartford Suspension Company, whose works are located at 150 Bay street, Jersey City, N. J., inform us that they have an autogenous welding equipment in their factory, and have done considerable work in welding since installing it, as it is the only equipment of the kind in the vicinity.

The R. L. Morgan Company, of Worcester, Mass., has increased its capital stock from \$300,000 to \$1,000,000, consisting of \$500,000 7 per cent. cumulative preferred stock and \$500,000 common stock. It is stated that the company has in hand orders for more than 100 trucks, and it is planning in future to manufacture all of the parts itself, instead of having them made by outside firms.

The petition of William J. Connell to have the Concord Motor Car Company, of Concord, Mass., adjudicated bankrupt under the section relating to manufacturing has been adversely decided by the Circuit Court of Appeals, which reversed the decree of the District Court. The Circuit Court held that the repairing of automobiles, in which line of business the company was engaged, is not a manufacturing pursuit in the meaning of the bankruptcy act.

Two hundred agents of the Studebaker Automobile Company held their annual convention in Chicago last week. General Manager Hayden Eames, Col. George M. Studebaker, president of the company and E. Q. Cordner, manager of the Chicago branch, were in attendance. A banquet at the Auditorium Annex and a discussion on trade topics at the local salesroom, with an address by E. Le Roy Pelletier, were some of the features of the gathering.

The municipal campaign in Indianapolis closed with a number of "whirlwind" tours. an innovation in political campaigns, and which proved very successful. On these tours the candidates for mayor rode in automobiles covering from nine to twelve meetings in an evening and making five minute speeches at each. In one instance a brass band riding in four automobiles preceded the arrival of the candidate at each meeting, played a selection, and then while the candidate was speaking hurried to the next meeting.

At the annual meeting of the Standard Roller Bearing Company, of Philadelphia, held last week, the following directors were elected for the ensuing year: Lenox Smith, Wm. D. Sloane, Isaac H. Clothier, W. B. Osgood Field, Henry De Forest Baldwin, Edwin Packard, Herbert Du Puy, Edward B. Smith, John C. Winston, George H. B. Martin, James Boyd, R. S. Woodward, Jr. These directors formally elected the following officers for the ensuing year: President, Lenox Smith; vice president, W. B. Osgood Field: vice president and general manager, R. S. Woodward, Jr.; secretary and treasurer, W. M. Baldwin.

# Club Notes

The Gloversville (N. Y.) Automobile Club has decided to affiliate with the New York State A. A.

The Huntington (W. Va.) A. A. has joined the West Virginia State Automobile Association. The Huntington organization has a membership of 160.

The Utah Automobile Dealers' Association, recently organized, at a meeting on October 19 decided to hold its show in the Auditorium on Richard street, Salt Lake City, February 19 to 26.

The Quaker City Motor Club, of Philadelphia, Pa., plans to acquire a clubhouse. L. D. Berger, the president, and Allen Shelden have been named to head a committee on ways and means of financing the project.

The A. C. of New Haven, Conn., has started upon the work of erecting road signs in that part of Connecticut. The club has had 100 signs made, and is soliciting suggestions from local owners for suitable points at which to erect them.

The Knoxville (Tenn.) A. C., at a meeting held on October 13, passed a resolution indorsing the action of the Birmingham, Ala., Chamber of Commerce in agitating the construction of an automobile route beween the latter city and New York via Knoxville and Chattanooga.

The contest committee of the Bay State Automobile Association at the last moment abandoned the two days' endurance contest which was to be held on October 21 and 22. Only 14 cars had been entered, and this was thought insufficient to warrant the committee in proceeding with the contest.

The Anniston (Ala.) Motor Club was organized on October 12 at a meeting held in the Chamber of Commerce with a membership of forty-five. The officers elected are W. H. McKleroy, president; J. C. Sproul, vice president; A. S. Johnston, secretary and treasurer. The club will affiliate with the State and national organizations.

The Louisville (Ky.) A. C. held a meeting on October 14, at which the prizes in the recent endurance contest of the club were awarded, except the trophy for endurance. Eugene Straus was elected president of the club, to succeed J. F. Ross, who resigned because he will shortly leave Louisville. Mr. Straus was formerly secretary of the club.

The Chicago A. C. has begun an investigation of the manner in which the money collected in fines by justices of the peace and other magistrates in Cook County is being spent. The Illinois law provides that the fines collected from automobile speed offenders are to be paid into the treasury of the highway commissioners of the township in which the offense is committed, and that all moneys so received shall be used

in repairing and improving the roads within the township.

The A. C. of Maryland, Baltimore, Md., plans to hold its second annual show early in the winter. The club plans to send a representative to the Atlanta Show to interest the Motor and Accessory Manufacturers in its exhibit.

The Asheville (N. C.) Motor Club held its second meeting on October 19, at which twenty new members were admitted and a board of governors elected. President Sawyer and Vice President Reynolds were instructed to look for permanent headquarters for the club and report at the next meeting.

The Scranton (Pa.) Automobile Association held its third annual meeting in the Board of Trade Auditorium on October 26. The following officers were elected: J. J. Germyn, president; Harry J. Carr, vice president; Thomas Sprague, J. L. Connell and Stéwart Scott, members of the board of governors...

A meeting of the executive committee of the Michigan State A. A. was held in Grand Rapids last week, the object being to consider a proposition to have the State Association and the Grand Rapids Club conduct jointly the Grand Rapids road race, in stead of having the race held by the Grand Rapids Club alone under a sanction from the State Association. It is considered that the proposed arrangement would bring greater support for the race, especially from Detroit manufacturers.

The A. C. of Delaware County. Pa., held its annual meeting in St. Philomena's Catholic School hall in Lansdowne on October 19. The club, which has been in existence for three years, has 410 members. All of the old officers were re-elected, as follows: J. H. Weeks, president; W. P. Anthony, vice president; J. E. Mitchell, treasurer; Dr. F. Marshall Harvey, secretary.

At a meeting of the Lowell (Mass.) A. C. on October 19 it was stated that after all bills in connection with the Lowell Carnival had been paid, there remained a surplus of about \$2,000. It was decided to distribute this among the parties who had raised the guarantee fund of \$10,000. The net deficit of the event therefore amounts to about \$8,000. It was decided to pay \$100 to Lieutenant John Crowley, who fell and fractured his left arm on the closing day of the carnival.

The Cleveland A. C. held its annual meeting on October 26. The secretary's report showed a membership of 792, as compared with 724 in 1908 and 631 in 1907. It was decided to change the club constitution so as to make the club year begin on January I, and with this object in view an adjournment was taken to November 2, to give constitutional notice of the proposed amendment. To fill the vacancies caused by the expiration of the terms of three members of the board of trustees, Harry L. Vail was re-elected and Fred J. Baird and M. Lawrence were elected members of the board.

Washington, D. C.—Royce Hough, Buick. La Crosse, Wis.—Alfred James, Franklin. Lancaster, Wis.—Stevens & Clark, Cadlac.

Wheeling, W. Va.—R. H. Mahlke, Stude-baker.

Cheyenne, Wyo.— F. R. Dildine, Stude-baker.

Grand Forks, N. Dak.—J. W. Lyons, Franklin.

Vinton, Ia.—Vinton Automobile Co., Mitchell.

Quincy, Ill.—The Collins Plow Co., Rambler.

Chicago, Ill.—The Tennant Motor Co., Marmon.

Philadelphia, Pa.-Wm. P. Berrien, Stoddard-Dayton.

Oklahoma City, Okla.—The Central Motor Car Co., Overland.

Chicago, Ill.—Ralph Temple Automobile Co., Baker electric.

Columbus, Ohio.—The Reese Motor Car Co., Detroit electric.

Milwaukee, Wis.—Geo. F. Gerlach, 1520 Grand avenue, Baker electric.

Kansas City, Mo.—The Genung Motor Car Co., 1710 Grand avenue, Fal.

Cincinnati, Ohio.—The Imperial Motor Car Co., Moon, Gaeth and White.

Minneapolis, Minn.—M. L. Hughes, 109 Sixth street, Rauch & Lang electric.

Philadelphia, Pa.—Prescott Adamson, Broad and Spring Garden streets, Reo.

Cleveland, Ohio.—The Euclid Sales Co., Firestone-Columbus and Columbus electric.

Wheeling, W. Va.—The Wheeling Automobile Co., South Side, Buick and Oakland.

Des Moines, Ia.—The Patton & Van Vliet Automobile Co., Grand avenue, Studebaker.

Washington, D. C.—Lester D. Moore, Jr., Reo. (Also nearly all of the State of Maryland, excepting Cecil County; the northern part of Virginia and eastern part of West Virginia.)

# Unlicensed Makers May Join New Patent Combination.

According to a trustworthy source a big combination among unlicensed automobile manufacturers is at present being formed in Indianapolis with a capital stock of \$4,000,000. The nucleus of the new combine is a rear axle patent, which is claimed to be fundamental. Three of the most prominent men in the unlicensed ranks have been represented at the meetings held in Indianapolis by counsel, and all three will be there personally next Saturday. One of the largest axle concerns in the country is also said to be interested in the new combine. The rights to the rear axle patents have been secured by two promoters who have been interesting the various parties above alluded to.

# New Incorporations

The Bemb Auto Sales Co., Detroit.—Capital stock, \$10,000.

University Motor Car Co., Detroit, Mich. —Capital stock, \$100,000.

The Capital Auto Company, Des Moines, Ia.—Capital stock, \$10,000.

The Automobile Exchange, Salt Lake City, Utah.—Capital increased from \$5,000 to \$50,000.

The Mitchell Motor Car Co., Racine, Wis.—Capital stock increased from \$1,000,000 to \$2,000,000.

The Wood-Kessler Auto Co., Toledo, Ohio.—Capital stock, \$12,000. Incorporators, George N. Fell and others.

The Star Carburetor and Supply Co.. Woonsocket, R. I.—Capital stock, \$100,000. Incorporators. John J. Lace and others.

The Buckeye Motor and Cycle Co.. Akron, Ohio.—Capital stock, \$5,000. Incorporators, Lucien B. Lyman and others.

The Piedmont Motor Car Co., Atlanta, Ga.—Capital stock, \$10,000. Incorporators, S. A. Wardlaw, Wm. D. Alexander and W. O. Wilson.

The Indiana Motor Sales Co., Indianapolis, Ind.—Capital stock, \$10,000. Incorporators, B. F. Meixell, D. J. Hayden and C. O. Britton.

The Central Motor Car Co., Oklahoma City, Okla.—Capital stock, \$10,000. Incorporators, John N. Shepler, J. Niblo and J. A. Niblo, Jr.

The Albany Motor Car Co., Albany, N. Y. —Capital stock, \$5,000. Incorporators, J. B. Wood, J. A. Wendell, F. S. Snyder and Frank A. Snyder.

The Carter Carburetor Co., St. Louis, Mo.—Capital stock, \$12,000. Incorporators. W. C. Carter, C. O. Baxter, Alden H. Little and W. C. Carter,

The Baker-Cameron Automobile Co., Dallas, Tex.—Capital stock, \$30,000. Incorporators, G. W. Baker, R. L. Cameron and L. E. Woodsend.

The Frank S. Bump Co., Binghamton, N. Y.—To deal in auto supplies. Capital stock, \$10,000. Incorporators, F. S. Bump, Austin S. Bump and Mona L. Bump.

The Harriman Garage Co. of Roane County, Tenn.—Capital stock, \$5,000. Incorporators, M. W. Thornton, M. Stowers, E. M. Kennedy, L. O. Scott and J. W. Scott.

Woodsdale Motor Car Co., Woodsdale, W. Va.—Capital stock, \$5.000. Incorporators Joseph Speidel, Jr., F. McL. Speidel, J. W. Speidel, B. S. McLure, and W. G. Caldwell, of Wheeling.

The Cushnoc Motor Co., Augusta, Me.—Capital stock, \$50,000. Incorporators, W. P. Cummings, Hallowell; C. B. Burleigh, Abner W. Nichols, P. H. Fitzgerald, Wm. Skehan, of Augusta.

The H. E. Wilcox Motor Car Co., Minvieapolis, Mir.n.—Capital stock, \$1,000,000. Incorporators, R. E., J. F., R. D. and F. E. Wilcox, G. W. Lewis and W. R. Cary, of Minneapolis, and D. H. Davidson, Jr., Carrington, N. Dak.

# Trade Personals

B. H. Pratt, of Fisk Rubber Co., who has had charge of the sales at Chicopee Falls, Mass., will in the future be manager of the Pacific Coast branch of the company.

W. G. ZAHRT, who has been manager of the general line sales department of S. F. Bowser & Co., Inc., Fort Wayne, Ind., has been placed in charge of the branch offices of that firm.

J. C. MATLACK, president of the Michelin Tire Co., of Milltown, N. J., has resigned. The resignation became effective November 1. Mr. Matlack will shortly announce his future plans.

J. H. McConnell has been appointed manager of the Fort Wayne general line sales department of S. F. Bowser & Co. Mr. McConnell was formerly assistant manager of this department.

HARRY BECK, Odd Fellows Temple Building, Broad and Exchange streets, Philadelphia, has been appointed secretary of the recently organized Philadelphia Garage Owners' Association.

A. E. VINTON has resigned his position with the G & J Tire Co., Indianapolis, with whom he had been for the past eight years. We understand that Mr. Vinton has several offers and will shortly announce his choice.

A. P. WARNER, president of the Warner Instrument Company, of Beloit, Wis., this week received his Curtiss aeroplane, purchased some time ago. He will make flights without expert assistance. The plane is the one used by Glenn H. Curtiss at the St. Louis centennial.

ERNEST A. Moross will sever his connection with the Indianapolis Motor Speedway Company, as director of contests, on November 14. It is reported that in the future he expects to devote his attention to promoting contests on various automobile courses, which his contract with the Indianapolis course prevented him from doing.

CAPT. WILLIAM MITCHELL LEWIS, president, and George B. Rogers, secretary of the Mitchell Motor Car Company, Racine, Wis., are on their way to Europe to attend the Olympia automobile show in London, following which they will tour the Continent and investigate the taxicab situation. They will also inspect the two European branches of the Mitchell, at London and Paris, which no member of the company has yet seen.

# Motor Vehicle Patents

Patents Issued September 7, 1904.

993,045. Water Circulating Pump.—Willian R. Andrew, Milwaukee, Wis., assignor to Interactional Harvester Co., a corporation of New Jesey. Filed March 25, 1909.

933,049. Vehicle Wheel.—Albert E. Beall and Charles F. Skellenger, Clinton, Ia. Filed June 19, 1908.

933,068. Power Transmitting Device.—Scend Fletchers, Traverse City, Mich. Filed March 13,

933,076. Shock Absorbing Apparatus.—Marie Houdaille, Paris, France. Filed March 1, 1995, 933,077. Gas Generator.—George F. Janhot, Paris, France. Filed April 28, 1908.

933,106. Tire Remover and Replacer.—Heary M. Owens, San Francisco, Cal. Filed June 16, 1908.

933,110. Tire Tread.—Charles L. Rempa, Akron, Ohio. Filed July 8, 1907.

933,115. Combination Spark Gap and Plag-Arthur L. Snyder, Pasadena, Cal. Filed May 15, 1907.

933,152. Tank for Storing Acetylene Gas-Percy C. Avery, Milwaukee, Wis. Filed August 27, 1906.

933,232. Power Transmitter.—Frank de Coligny, Chicago, Ill., assignor to Coligny Hydranic Transmission Co., a corporation of Michiga. Filed October 21, 1908.

933,233. Hydraulic Clutch.—Frank de Coligny, Chicago, Ill., assignor to Coligny Hydraulic Tranmission Co., a corporation of Michigan, Filed April 8, 1909.

April 8, 1909.

April 8, 1909.

933,293. Vehicle Axle.—Charles T. Cullison,
Worthington, Ind. Filed January 18, 1909.

933,320. Roller Bearing.—Onesime E. Michaud,

St. Louis, Mo. Filed December 5, 1908.
933,367. Governor or Speed Regulator.—Alberd
de Dion and Georges Bouton, Puteaux, France.

Filed February 9, 1909.
933,420. Lock Nut Device.—Julius S. Conradi.
Belvedere, Edward Tilston, Manchester, and Peter
W. Masson, Belvedere, England. Filed January

27. 1909.
933,467. Speed Indicator.—Carl Knopf, New York, N. Y., assignor to Hicks Speed Indicator.
Co., Brooklyn, N. Y., a corporation. Filed May 24, 1907. Serial No. 375,535. Renewed May 15

933.494. Friction Clutch.—Milton S. Slauda and Thomas J. Kelly, Everett, Wash. Filed Sep

tember 1, 1908. 933,496. Wind Shield.—James H. Sprage. Norwalk, Ohio. Filed January 28, 1909.

933,607. Acetylene Gas Generator.—William A. Woods, Watsonville, Cal., assignor to Harry D. Freiermuth, Watsonville, Cal. Filed March 19, 1908.

933,614. Headlight.—Charles L. Betts, New York, N. Y., assignor to R. E. Dietz Co., New York, N. Y. Filed April 23, 1908.

933,684. Hydrocarbon Burner.—George E. Whitney, Boston, Mass., assignor, by mesne assignments, to Stanley Motor Carriage Co., a corporation of Massachusetts. Filed August 9, 1960. 933,686. Block for Vehicle Springs.—Thoms. Wright, Jersey City, N. J. Filed April 6, 1909. 933,694. Means for Igniting and Controlling Vehicle Lamps.—Alfred A. Clark, Baltimore, Md. Filed April 24, 1908.

933,704. Lifting Jack.—Frank L. Gormley.
Boston, Mass. Filed February 15, 1909.
933,705. Lifting Jack.—Frank L. Gormley.
Boston, Mass. Filed February 15, 1909.

933.709. Mixing Attachment for Internal Combustion Engines.—John Illy, Jamestown, N. Y. Original application filed May 10, 1907.
033.715. Pneumatic Tire for Automobiles and

Other Vehicles.—Charles A. Lewis, Denver, Calassignor of one-half to William A. Diboll, Denver, Col. Filed September 28, 1908.

# The Horseless Age

First Automobile Journal in the English Language

**VOLUME XXIV** 

NEW YORK, NOVEMBER 10, 1909

NUMBER 19

# The South's First National Show.

Few there are who realize the full meaning of the National Automobile Show held in Atlanta, November 6 to 13. Few appreciate it from the South's standpoint. The great majority look upon it as a complete exhibit of automobile lines and accessories. Such it is, undoubtedly. Automobile authorities have so classed it, placing it in the same category with the three other annual national shows that have be-

come fixtures in the calendar of the North and East.

But the more astute and far seeing among the authorities see in the show another significance-a greater significance; that is, the essential element of the Southern appreciation of the big exposition. They see in it the manifestation of awakening of the South as a rich and practically virgin automobile market. They realize its deeper meaning.

RESULT OF LOCAL FIGHT.

From a combination of circumstances

grew the Atlanta Show. It had its beginning in a protest against further continuance of the annual State fairs that for many years had been held in Atlanta. A contingent of Atlanta citizens during the last fair held in the fall of 1908 put their objections in written form and signed them, and organized to uphold them. The result of a rather complicated local fight was that the annual State fairs were wiped off the slate.

A demand existed for something to take their place in bringing visitors to Atlanta. The capital city of Georgia has prospered by keeping open house during many years, and there was no logic in a sudden discontinuance of its liberal policy.

An automobile show was suggested, and the suggestion received immediate support. Euthusiasm grew with each reversion to the subject, and the Atlanta Automobile Trades Association was organized among the automobile business directors of the city to stand sponsor for the show and work out its details.

ORIGINAL PLANS MODEST.

Small beginnings are sometimes responsible for bigger results than are anticipated. The original project for the show was modest in its pretensions. The plan was to exhibit as many cars of 1909 as could

THE AUDITORIUM-ARMORY WHERE THE SHOW IS HELD.

be gotten together by the local dealers, wherever they could be presented, and as soon as possible. The use of the city's magnificent new Auditorium-Armory, then (in April) just completed, was desired, but the desire did not meet with a great deal of spontaneous accord by the Auditorium-Armory management.

The minor importance of such a show forced itself upon the realization of the moving spirits in the project, and they began to lose heart. Just then a voice that had been persistently insisting on "a national show or none at all" began to be heard more and more loudly. The slogan became a chorus, timid enough at first, but growing more vigorous each day.

"We can't get a national show," was the opinion generally expressed. "Only two are held each year, and the big cities of the East and North get those. Atlanta would not be considered. Manufacturers would

not show their 1910 models here before they show them up East. And we don't want to wait till everybody has looked them over elsewhere before we bring the new cars here."

"NATIONAL SHOW OR NONE."

But the "national show or none" slogan won out, and with many misgivings a committee of Atlanta men went to New York

to confer with show authorities and leading manufacturers. The manifold details of their work during tedious days and weeks of all sorts of discouragement are hardly worth the telling now. Their success shines upon it all. Suffice it to say that they were tenacious, and that they won. They enlisted the friendship of influential automobile men who knew the city and its spirit. They argued away all objections. For this bigger enterprise the Auditorium-Armory had been placed freely at their disposal, and they

presented its advantages convincingly as the newest, largest and most complete edifice in the South.

And finally they swept away the last barrier, and won. The word "success" that they put upon the wires thrilled the whole South. The seemingly impossible had been accomplished, and a national automobile show had been secured for Atlanta; the first ever held south of Chicago, and the first of the year for exhibition of 1910 models.

#### FUTURE MANAGERS ON THE SCENE.

On April 28, S. A. Miles and Alfred Reeves arrived in Atlanta to look over the field for themselves. They were to combine their experience in managing the show. As general manager of the National Association of Automobile Manufacturers and general manager of the Motor Car Manufacturers' Association, their visit to the city, and their inspection of the conditions af-

forded the first real official recognition to the project. They signed the contract with the Atlanta committee on April 29 for a national show to be held in Atlanta from November 27 to December 4, inclusive. Later these dates were changed to November 6 to 13, inclusive. From the moment of the signing of the contract till the brilliant opening of the show on November 3, there was no cessation in the busy preparation for the big exhibition.

The thoroughness of complete experience characterized the working out of all the many detailed plans for the show. No detail was overlooked. Expert minds made the last square inch of floor space available in the building, devoting finally to the show's purposes more than 60,000 square feet of floor surface; little enough, in comparison with some other figures, but admirably distributed, though every foot of it was taken and there was still demand for more.

Atlanta's newspapers, notably the Journal and the Constitution (pioneer workers in the movement, and consistently ardent supporters of it), cordially and absolutely pledged themselves to the success of the show. In complete harmony the Atlanta press worked and boosted. The time was ripe. The moment was psychological. The infection of acclaim spread rapidly through Georgia, and soon swept the South and found its reflection in the North. Immediately there was fruition in Atlanta. Associating automobiles with the incipient campaign for good roads, one newspaper secured the partnership of a New York daily, and together they launched a movement for a national highway to connect New York and Atlanta, and to be dedicated to the purposes of travel and the slogan of good roads by a time table tour from the former to the latter city. Another Atlanta newspaper followed suit with a manifold project for endurance runs from Georgia points. The automobile race bud bloomed, and the Atlanta Speedway was begun. The first of these three came to a successful conclusion three days before the show started. The second rivaled that success just after the commencement of the show, and the races brought their culmination to the whole, while the show was in full swing.

On the afternoon of Saturday, November 6, the doors of the show were opened. Robert F. Maddox, mayor of Atlanta, welcomed the exhibition's attending caravans of visitors, and gave expression to the city's best wishes for success of the show. Asa G. Candler, banker and capitalist, head of the Atlanta show committee, declared the show officially opened and pressed the button that threw the brilliant flash of life into the big exposition.

Most of the accessory exhibitors were assigned to space on the second floor of the armory section, or on the third level of the building's construction, the mezzanine floor intervening between them and the main floor of the armory into which the entrance opened. Access to this exhibit was to be had by a single flight of stairs. There was some complaint on the first evening of the show that this floor was not sufficiently lighted, and a petition signed by the exhibitors presented the matter to the show

authorities. A varied exposition of articles pertaining to automobiles was offered here.

#### Gasoline Cars.

PREMIER MOTOR CAR COMPANY, Indianapolis, Ind.-Two cars and a classes are shown here, and many noticeable features are seen. The make and break spark is used, and the spark mechanism is provided with a cushioning device which permits considerable wear without need of adjustment or delicacy of adjustment when made. The insulated electrode is well in toward the combustion space, so the gas travels past it and keeps it clean and cool as well as insuring that even at very low throttle the new gas will be in reach of the spark and sure to ignite. The cylinders are enameled with a high heat enamel They are capped by a ribbed sheet stell cap, with ground joints, which is flexible enough to prevent damage, even if the water is allowed to freeze. The incoming gases pass into a water jacketed chamber The fan has an eccentric adjustment, as has also the steering gear, so the lost mo-tion may be taken up. The motor and transmission rest on pressed sub-frame members, which join the main frame at the front to make a hollow box structure of great stiffness. This sub-frame continues back to a cross member and stiffens the main frame at the point where it is narrowed for roomy turning. A multiple disc clutch is used dry, and a telescopic shaft is used between the clutch and transmission, so either can be taken out without much trouble.

GENERAL VIEW OF A SECTION OF THE MAIN FLOOR.

VIEW OF ONE END OF THE MAIN FLOOR.

PIERCE ARROW MOTOR CAR COMPANY.

Buffalo, N. Y.—Pierce cars are shown in nothing but sixes. The 36 horse power car has had its motor bore increased from 318 inches to 4 inches, and the wheels are 36 inches instead of 34 inches. The tires have likewise been increased a half inch, being now 4 and 41/2 inches. The wheel base has been brought up to 1241/2 inches instead of 110 inches, and in other ways the car has been made to correspond to the increased power and length. A single vibrator with a six unit coil is used in the ignition system, and magneto and battery are both supplied. A gasoline gauge is supplied on the dash. Spencer power air pumps are also part of the equipment, and lessen the tire pumping nuisance. The 48 horse power has larger wheels and tires than last year, using 37 inch by 5 inch rears and 36 inch by 41/2 inch fronts, instead of 36 inch rears and 4 inch fronts. These larger wheels have been fitted with Timken roller bearings all around, instead of the ball bearings heretofore used. The base of the 48 horse power car has also been lengthened from 130 inches to 1341/2 inches, largely by bringing the front axle nearly to the front of the radiator. Grease cups are now fitted to the spring bolts instead of oil cups. The outlines of the top, and particularly the stationary part of the side curtains, are noticeable.

## POPE MANUFACTURING COMPANY,

Hartford, Conn.—At this exhibit are shown four cars, viz., seven and five pasenger touring cars, a pony tonneau and a four passenger roadster. Among the improvements made may be mentioned the adoption of distance rods for the rear axle instead of depending on the front end of the spring

to perform this service. The semi-elliptic springs now have shackles at both ends, and are free to extend under action in both directions. They are mounted to swivel around the axle, and are provided with bronze bushings made dust tight and oil retaining by felt washers. Last year the torsion was taken not only by the springs but by the single torsion rod provided, but this year a double or V rod is used with vertical spring coils at its ball end to take the shock and resist the torsion of the axle. The spring irons extend well to the rear, and permit the use of springs 56 inches long, with very easy riding effects. The bodies are deeper than last year, and are cut out under the seats to admit the higher fenders, made necessary by the use of 36 inch instead of 34 inch wheels.

## LOCOMOBILE COMPANY OF AMERICA,

Bridgeport, Conn.-Few changes are to be found in this well known design of car, as the makers claim they cannot better a vehicle which has proven satisfactory in all its details. The larger car is now fitted with slightly lower body to better the riding qualities, and give it a more rakish appearance. This lessens the wind resistance and also makes the body more nearly resemble that of the smaller car. The larger motor is 5x6 inch, while the smaller is 41/2 inch square. One of the special features is the crank case base of bronze which, although a little heavier, is tougher and more rigid than the usual aluminum base. In the carburetor the increased air supply is through a conical coil spring, the coils of which open as the air suction increases. Both a foot throttle and a hand throttle are provided. There is also a governor which controls the throttle at any desired point. One of the most noticeable features—since it is found on but few machines—is the make and break spark ignition. A simple magneto supplies the make and break plugs with current.

# THE PACKARD MOTOR CAR COMPANY,

Detroit, Mich., are showing a five passenger touring car, a limousine and a seven passenger touring car. The five passenger car and limousine are on the 18 horse power (French rating) chassis, while the seven passenger is shown on the 30 horse power (French rating) chassis. The principal change over the 1909 car is the use of a multiple disc dry plate clutch instead of the expanding one formerly used. The cylinders are cast in pairs, with the valves on opposite sides and operated by two cam shafts. The clutch, as above mentioned, is a dry plate. The crank case is in three horizontal sections. The lubrication is through a positive feed oiler driver by a worm on the exhaust cam shaft and splash from the crank case, where a constant level of oil is maintained. Ignition is jump spark, the current being supplied by an Eisemann low tension magneto and storage battery for starting the motor from the seat. The transmission gives three speeds forward, and is located on the rear axle. The front axle is tubular and the rear axle full floating. The brakes are internal expanding and external contracting, operating on the rear wheel brake drums. The wheel base on the "18" is 112 inches, and the motor has a 416 inch bore and 51/8 inch stroke, while the wheels carry 34x4 inch tires. The wheel base on the "30" is 1231/2 inches. The motor has a 5 inch bore and 51/2 inch stroke, the wheels carrying 36x4 inch front and 36x41/2 inch rear tires.

PREMIER MANUFACTURING COMPANY'S STAND.

THE WINTON MOTOR CARRIAGE COMPANY, Cleveland, Ohio, have on exhibition one five passenger touring car, one four passenger toy touring car and one stripped chassis, all on the 48 horse power, six cylinder, standard chassis. The cylinders are of 4½ inch bore and 5 inch stroke. These cars have the only self starting motors shown in the building. They have a multiple disc clutch and selective type transmission, with four forward speeds, and are the only \$3,000 cars shown with four speeds. The wheel base is 130 inches. A complete detailed description of these cars is to be found elsewhere in the paper.

MATHESON MOTOR CAR COMPANY,

Wilkes-Barre, Pa.-The well known Mathesons are made in seven styles, the torpedo and gunboat designs of body being new with them. Owing to limited space but two styles are shown. The Matheson Six has six cylinders, with valves in the heads and of a bore of 41/2 inches by a stroke of 5 inches. A double ignition system is used. The gasoline tank is pressure acting, and a pump is fitted on some models at the front of the driver's seat where it can be easily reached. The transmission is carried at the rear axle, forming a two unit construction, with long propellor shaft and consequent slight angle of the joints. The clutch is a multiple disc type, and has fiftyone discs. The motor has a wide range, and with a speed of 60 to 65 miles per hour can also run down to 4 miles per hour on the high gear. These cars are guaranteed to do at least 12 miles per gallon of fuel. Tire carriers, a trunk rack and similar fittings are part of the regular equipment. The rear springs are three-quarter elliptic and add to easy riding, while the low deep bodies of the torpedo and gunboat styles are largely exempt from wind resistance and ride comfortably at speed.

#### MITCHELL MOTOR CAR COMPANY,

Racine, Wis.—Three models of the Mitchell are shown. The roadster, with a 30-35 horse power motor and 100 inch base, had last year but 20 horse power and 92 inch wheel base. The five passenger touring car uses much the same motor, but the wheel base is 115 inches instead of 106 inches. Both of these use three-quarter elliptic

springs, and the touring car has a floating rear axle. On it the wheels are now of 34 inches diameter instead of 32 inches as formerly. Both of these are of the four cylinder type. The Model S is a six cylinder car, of 50 horse power and with cylinders of 41/4 inches by 5 inches. It is built either with seven passenger body or close coupled body for five. As the power increased from 40 of last year, so the wheel base increased from 124 inches to 130 inches, and the wheels from 34 inches to 36 inches. The sub-frame formerly used for the transmission has been left off and the appearance of the chassis has been much simplified. Now a torsion tube around the propellor shaft is used, and at the front end of this is the transmission, which is pivoted or yoked to a cross member of the frame. This arrangement avoids universal joints between the transmission and the rear axle, and simplifies the construction very considerably.

### MOON MOTOR CAR COMPANY,

St. Louis, Mo .- The Model 30 is a new car, selling at \$1,500, and fitted with a four cylinder motor of 41/4 inch bore by 5 inch stroke. The cylinders are T shape and have valves of 21/4 inches diameter. The transmission is at the rear, and gives three speeds forward and reverse, on the selective principle. The wheel base is 110 inches, and the wheels are 34 inches with 4 inch tires on the touring car and 31/2 inch tires on the roadster. Magneto and batteries are furnished, using a single set of plugs. Brakes are expanding and contracting in drums 12 inches by 2 inches face on the rear hubs. The control is identical with that of the Model 45, which has been marketed for the last six years. This is also shown in improved form for the coming year. Its wheel base has been lengthened from 112 inches to 120 inches, and 36 inch wheels are used with 41/2 inch rear tires and 4 inch front. The horse power of the motor has been increased to 45 instead of 30-35. as last year, by increasing the bore and stroke to 41/4x5 inches. The valves are in the head, with overhead shaft. Magneto, four speeds ahead and a special type of rear axle are some of the features. In the 30, the flywheel has fan spokes, which does away with the necessity for fan bearings. The clutch is a special patentel device used two seasons.

#### ST. LOUIS CAR COMPANY,

St. Louis, Mo.-The Standard Six is a new car with a number of good features The valves are in removable cages in the heads of the motor. The cylinders are cast in pairs and are 41/2 inches by 5 inches size. The valve action parts are all hardened Large hand holes are provided in the case for easy access to the connecting rod ends. Lubrication is by splash, with pump to maintain the level and dash sight to be sure of the feed. A noticeable feature is the three point suspension of the motor, which has two points fastened at the front, and the rear swivel in a large bearing so as to be free from any twisting motion of the frame. Magneto and battery are furnished. The clutch is of the inverted cone variety, with leather face and cork inserts. The transmission uses annular bearings, and the wheels employ roller bearings throughout The frame is raised at the rear, and carried there on platform springs, all the holts of which have grease cups. At the front the frame is narrowed to increase the wheel turning space. The wheel base is 124 inches and the wheels are 36 inches, with quick detachable tires of 4 inch section. The brakes are equalized, and the steering gear and segment are adjustable for wear.

## THE MARION MOTOR CAR COMPANY,

Indianapolis, Ind., show one Gentleman's speed car and one five passenger touring car. The motor is four cylinder, east in pairs, with valves all on one side and operated by a single cam shaft. A multiple disc clutch is used, together with a three speed, selective type sliding gear transmission. The discs in the clutch run in an oil bath. The rear axle is full floating type, while the front is an I section drop forging. Semi-elliptic springs are used in front and full scroll elliptic at the rear. Cooling is effected by a cellular radiator, a centralugal pump and a ball bearing fan. Ignition is by Splitdorf magneto and batteries through a single set of spark plugs. The wheel base is 112 inches and 34x4 inch tires are used on both cars.

#### THE MURA MOTOR COMPANY,

of Newark, N. Y., show a Mora Tonrer, he passenger; a Mora roadster, four passenger; a Racytype, with double rumble seat, and a Model 20 runabout. The motors in these cars have 41/2 inch bore, 51/8 inch stroke, cylinders cast in pairs, with the exhaust and intake valves on opposite sides, operated by separate cam shafts. All the motors are four cylinder. The motor, clutch and transmission are all protected by a cast aluminum pan. The clutch is of the inverted cone type, and leather faced. The transmission is three speeds forward and reverse, selective type sliding gear. The carburetor is provided with independent adjustments for slow and high speeds, and an

adjustment for regulating the height of gasoline in the float chamber, which latter is made of tempered glass, so one can readily see in case of trouble whether the level of gasoline in the float chamber is right or there is a stoppage in the supply line. The ignition is by jump spark, with magneto and batteries working through a single set of spark plugs. Each system is independent of the other. Lubrication is by a self contained oiler in the lower half of the crank case, the oil being pumped from the reservoir to the bearings and splash basins by a gear driven pump, maintaining a constant level of oil. Cooling is effected by a radiator of the vertical tube design, a centrifugal pump and a gear driven fan. Brakes are internal and external, operated in the usual manner. Wheel base, 112 inches, with 34x4 inch tires

#### CADILLAC MOTOR CAR COMPANY.

The demand for more power has resulted in the four cylinder Cadillac being made with a bore of 41/2 inches, instead of 4 inches as heretofore. The wheel base has been lengthened from 106 inches to 110 inches, and the wheel sizes from 32 by 312 inches to 34 by 4 inches. To accommodate these larger wheels the frame is raised over the axle, but drops down to the rear thereof instead of continuing back in the raised level as heretofore. Brake drums have been enlarged and the details of the brakes have been somewhat changed. The front axle is now an I beam. Magneto and also the Delco system, consisting of vibrator and relay, are used. The brake and clutch pedals are now made adjustable to permit fitting to the user's needs. Gas lamps are now a part of the regular equipment as well as oil lamps. Three cars and a chassis are exhibited, the chassis being fitted with glass sides to the engine case, and a glass top to the transmission and with electric lights therein, so the working of the parts may well be seen.

## THE FORD MOTOR COMPANY,

Detroit, Mich., are showing one roadster, one town car, one five passenger touring car, one tourabout and one coupé, all on their standard chassis. These different style bodies are interchangeable with each other, making it possible for a purchaser to provide a car for various purposes by buying the extra bodies desired. The motor is a four cylinder, cast en bloc, with 334 inch bore and 4 inch stroke. The power plant and transmission are a unit with three point suspension. The valves are all on one side and operated by a single cam shaft. The ignition is by a low tension magneto generator of Ford design. This magneto has no commutator or brushes, no gearing, no contact points, no moving contacts and no moving wires. The rotating member is a part of the flywheel. The stator carrying the coils in which the current is generated is a stationary spider permanently attached to the motor, and the whole thing carried in the flywheel casing. No battery is used in connection with the magneto.

The transmission is planetary, with full control by pedals. The clutch for high speed is a multiple steel disc clutch operating in oil. Cooling is by thermo-siphon circulation and fan. An entirely new design of float feed automatic carburetor, with dash adjustment, is used. There are two sets of brakes, a service band brake on the transmission operated by pedal, and expanding brakes in the rear wheel hub drums controlled by a side lever. The wheel base is 101 inches, with 30x3 inch front and 30x3½ inch rear tires.

#### REO MOTOR CAR COMPANY.

Lansing, Mich.—Reo cars have a worthy addition in a four cylinder chassis fitted either as a roadster or touring car at \$1.250. The previous models are continued, but their precedents are departed from in several important particulars. The new motor has 30 horse power, 4 inch by 41/2 inch cylinders, cast in pairs; inlet valves cast in the heads, exhaust valves on the right side, by which arrangement large valves are secured. The water piping directs the coolest water to the exhaust valves from a honeycomb radiator. The transmission is selective, the clutch multiple disc with positive release, and the shaft joints are encased in oil. Three speeds forward, large fuel capacity, double brakes, battery and magneto and similar up to date features mark the car. The wheels are 34 inches with 31/2 inch tires. The wheel base is 108 inches and the speed up to 50 m. p. h. The front wheels are ball bearing, the rears roller bearing, with balls at the gears.

# YORK MOTOR CAR COMPANY,

York, Pa.—These cars are shown with very little change from preceding years. The use of full floating axles is, perhaps, the most radical difference. The motor stroke has been increased from 45% to 43% inches, the bore remaining 4½ inches. The comfort of the driver has been helped by mak-

ing the steering wheel 17 inches in diameter instead of 15 inches as in the past. The brakes are now double on the rear hubs instead of one on the drive shaft. The fenders have been changed in design. On the Model 40 the cylinders are of 5 inch bore by 51/2 inch stroke, while on the Model 50 the bore is 51/4 inches by 6 inch stroke. Magnetos and batteries are used, and there are four speeds forward on the larger cars. Wheel bases run 108, 112 and 124 inches. The clutches are conical, with cork inserts. The wheels are 34x31/2 inches, 36x41/2 inches and 36x5 inches. The frames are raised at the rear to get over the axles and narrowed at the front. One of the special features of these cars is the casting of the cylinders separately, but with abutting sides of water jackets open. These are afterward bolted together and make practically a block casting, but with the advantage that the block can be separated at any time for cleaning or inserting a new cylinder, if this should become necessary. Offset cranks are used and double cam shafts, one on each side of the motor.

#### AUSTIN AUTOMOBILE COMPANY,

Grand Rapids, Mich.-The Austin cars do not show much change. Believers in color effects, they have stuck to an ivory white, trimmed with tan, for six years, and show a car of this finish; also one "all golden brown" which is very rich in appearance. In their Model 45 they have increased the motor to 41/8 by 51/4 inches, with considerable gain in power The wiring of the motors has been bettered also. The Model 50 is a new car, much like the 60-90, and like all the others having six cylinders. It has a motor 41/2 inches by 6 inches, claimed to be very economical and accessible. The cylinders in this car are cast separately and the crank shaft has seven main bearings. The clutch is multiple disc, the transmission has four forward speeds and annular bearings, and the rear axle

POPE STAND, SHOWING MURAL DECORATIONS.

is of the floating type, while the front is of I section. The carburetor is a special with usual automatic adjustment and special adjustment from the seat for slow speeds and starting. The wheel base is 134 inches and the tires 36 by 4½ inches, while on the Model 60 the tires are 37 by 5 inches. Two complete and separate ignition systems are furnished.

#### THE PEERLESS MOTOR CAR,

Cleveland, Ohio, show three machines, a close coupled, five passenger, touring car, a seven passenger touring car, and a demi limousine. This latter is somewhat of a novelty. There have been no radical changes in this make of car for the past three years, but this year there has been quite a crop of refinements. Among these may be mentioned the use of spiral gears in place of bevel gears for the fan drive; an oil reservoir cast integral with the crank case, and ready means for draining out and refilling the crank case from the oil reservoir; a spring connection between the pedal and the operating collar of the clutch greatly facilitates the easy engagement of the clutch in the hands of a novice. An eye affixed to the gear shift lever, and a corresponding one on the "gate" permits the gears to be locked in the neutral position by means of any ordinary padlock. Another minor but at the same time substantial improvement is an arrangement by means of which the foot brakes may at any time be taken up by turning a wing nut which may be got at by taking up one of the foot boards.

# THE F. B. STEARNS COMPANY,

Cleveland, Ohio, are showing one seven passenger "30-60," one "15-30" landaulet, one "15-30" toy tonneau and one "15-30" polished and spotted chassis. The seven passenger "30-60" is four cylinder, with the 5\%x5\% inch cylinders cast in pairs, and valves all on one side. The clutch is a multiple disc, and is used in connection with a four forward speed selective type transmission.

The drive from the transmission is through chains to a sprocket on each rear hub, or the car can be had with shaft drive. The ignition on the "30-60" is by two separate jump spark systems, each with its separate set of plugs. The current source for one system is a Bosch high tension magneto, and for the other batteries supplying a Connecticut coil. The wheel base of the chain driven car is 121 inches, that of the shaft driven car 124 inches. The "15-30" has its cylinders cast en bloc, with all valves on one side. A multiple disc clutch and a three forward speed transmission of the selective type are some of its features, and the car is very similar to the "30-60," except that the latter always comes with shaft drive. No changes of consequence have been made in the general make-up of these cars. The rear axle, however, is out of the ordinary, since it is a solid drop forging bored out to receive the differential and floating axle. The "15-30" has a Bosch dual system of ignition. All models are regularly equipped with Continental demountable rims.

THE APPERSON BROTHERS AUTOMOBILE COM-PANY.

Kokomo, Ind., are showing one toy tonneau Jack Rabbit, one gentleman's speed car Jack Rabbit, one seven passenger, 40 horse power touring car and one five passenger, 30 horse power touring car. The motors are all similar, except as to size, having four separate cast cylinders, with valves on opposite sides. The toy tonneau has a 40 horse power motor, with 434 inch bore and 5 inch stroke. The speed car has 534 inch bore and 5 inch stroke, while the 30 horse power has 43% inch bore and 5 inch stroke. All the cars are equipped with the well known Apperson contracting band clutch. The cooling is by a vane pump and fan. The double system of ignition with two sets of spark plugs, together with magneto and batteries, is used. The transmission is a three speed forward selective. The speed car and toy tonneau use chain drive, and the other cars the shaft. There have been no changes of any importance made this year, and those changes that have been made relate to minor details. The shaft drive cars are equipped with semi-floating rear axles. The wheel bases of the several cars are: Toy tonneau, 116 inches; seven passenger, 122 inches; five passenger, 112 inches, and speed car, 116 inches.

THE NATIONAL MOTOR VEHICLE COMPANY Indianapolis, Ind.—Two machines are on exhibition at this stand, a four cylinder, five passenger, and a six cylinder, seven passenger. Both are equipped with ton-neau bodies. No radical changes are made ir. this year's models. The four cylinder "40" has had its wheel base increased to 125 inches, and the power slightly increased The main characteristics of the four and the six are the same, the cylinders cast in pairs, with valves on both sides. The constant level force feed system of lubrication is used. Two complete systems of ignition are provided-Bosch magneto and a single coil and distributor. The clutch is of the self contained cone variety, with springs under the leather to facilitate easy engagement. The transmission is of the three speed selective gate change type. The cylinder dimensions of the "40" are 5x5 11-16 inches. They have two sizes of sixes, a 50 horse power, with cylinders 43/x414 inches and a "60" which is 5x5 inches.

THE ELMORE MANUFACTURING COMPANY, f Clyde, Ohio, are showing one seven pas

of Clyde, Ohio, are showing one seven passenger, 50 horse power touring ear, a five passenger, 36 horse power touring car, a demi tonneau car and a 36 horse power stripped chassis. The five passenger and demi tonneau are both on the standard # horse power chassis, and have a four cylinder, two cycle, thermo-siphon cooled motor. with the cylinders cast separate. The well known Atwater Kent ignition is used on all models. The clutch used on the different models is the Elmore expanding ring. and is bronze to cast iron. A selective type transmission is used on all models, as well as a semi-floating type of rear axle. The lubrication on these motors is out of the ordinary, inasmuch as the oil is fed into the intake pipe and is supplied through it to the inner chambers.

## THE BARTHOLOMEW COMPANY,

Peoria, Ill., showing the Glide, have one special 45 horse power, seven passenger, touring car and one four passenger, 45 horse power roadster. These two models use the one standard chassis. The motor is a four cylinder, with the cylinders cast separate and valves all on one side. The cylinders are of 434 inch bore with 5 inch stroke. The clutch is a multiple disc running in oil, with a three speed selective transmission located on the rear axle. The ignition is by a double jump spark system, with two sets of spark plugs, working with a high tension Eisemann magneto and a storage battery, respectively. The

THE REO STAND.

steering gear is quite different from the usual worm and gear type, consisting of a large bevel gear with double links connecting with the steering arm. The torque and driving strains of the rear axle are carried on a central cross member of the main frame through a tube and radius rods which run back to the brake drum flanges. The brakes are exceptionally large, being 16 inches in diameter, with 3 inch face. Besides the complete cars there are also on exhibition several groups of parts, such as the various parts of the steering gear, parts of the transmission and the complete rear axle, with the transmission and differential housing open to inspection.

#### THE DAYTON MOTOR CAR COMPANY,

of Dayton, Ohio, show five cars—a five passenger, 40 horse power touring car; a 50 horse power touring roadster, a 50 horse power, seven passenger touring car, and a limousine of the same horse power. The motor has undergone quite a few changes, which are rather interesting. In this year's models two rocker arms are used, one set to operate the exhaust valves and the other the inlets. These are actuated from separate cam shafts on opposite sides. Roller bearings are used on the rock shafts. The cylinders are cast in pairs as formerly The exhaust valve cages are held in position by a double voke which is retained by a castellated nut on a stud bolt. Two complete ignition systems are in use, a magneto system and the Dolce single spark system. Another special feature about the motor is the new Stoddard-Dayton carburetor, which is so arranged that as the auxiliary valve opens a second jet is gradually brought into action. Pressure feed for the gasoline has been adopted on this year's models. The bodies on these cars exhibit a number of interesting features. The runabout top is supported well forward and breaks just back of one of the rear stays. which brings the top when lowered well away from the rumble seat.

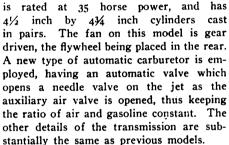

# THE NORDYKE & MARMON COMPANY,

Indianapolis, Ind.—Three Models 32 are shown by this concern, one a lead colored chassis, a runabout with elliptic gasoline tank back of the front seat, and a close coupled "suburban" car. The motor on this car has four cylinders, cast in pairs, with valves on opposite sides, the cylinder dimensions being 4½x5 inches. Bosch dual ignition is used. The clutch is of the cone type, faced with a special asbestos fabric with relieving spring. The lubrication is by a circulating system, with a hollow crank shaft, through which the oil is forced to the main bearings, as well as to the crank pins and wrist pins. The gear is of the three speed, selective type, and is located on the rear axle. A peculiarity of the construction is that the operating levers are housed in the hollow torsion rod. The rear axle construction is such that the differential and change gear can be removed through an opening in the axle casing, to the rear without removing the same from the frame. A very ingenious and simple take-up device is provided for both brakes, which are well equalized. Full elliptic springs are used in the rear.

#### THE STEVENS-DURYEA COMPANY,

Chicopee Falls, Mass., show a Model X, four cylinder touring car, and also a limousine on the same chassis; also a Model Y.

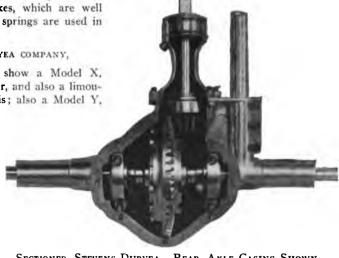

six cylinder, seven passenger touring car, and a Model X chassis. They have this year brought out a small six, known as the Model AA, which is shown with a touring car body. This has a wheel base of 128 inches, and 36x4<sup>1</sup>/<sub>2</sub> inch tires in front and rear. The motor

THE MAXWELL-BRISCOE MOTOR COMPANY. Tarrytown, N. Y., show their AA runabout, which, in the main, has not been changed from last year's model, it having a double opposed, 4x4 inch motor, with a wheel base of 82 inches and 28 inch wheels. transmission is of the planetary type, giving two speeds and reverse. The 1910 cars of this model will, however, be fitted with the combined battery and magneto ignition now used on all models of this make. A new car brought out this year is the Model Q. This has a four cylinder, 33/4x4 inch motor, with valves on opposite sides. The wheel base is 93 inches, and the wheels are 30x31/2 inches. A multiple disc clutch is used, and a three speed and reverse sliding gear transmission. The clutch and gear are interlocked so that the gear cannot be shifted unless the clutch is withdrawn, or the clutch engaged unless the gear is properly in mesh. The Model G is designed on similar lines, but with a 41/4 x 41/2 inch motor, a wheel base of 110 inches and 34x4 inch tires. The cooling of all models is by thermo-siphon circulation. On both these models the left hand pedal first releases the clutch, and then applied the brake.

# THE H. H. FRANKLIN MANUFACTURING COMPANY.

The main mechanical features of the 1910 models are the abolition of the fan at the front, and the use of a suction fan integral with the flywheel in the rear; the use of a horizontal partition and jackets which surround the cylinders so that the air is drawn downward through these, thus ensuring uniform cooling of every cylinder. The cooling fins have been made vertical to render

SECTIONED STEVENS-DURYEA. REAR AXLE CASING SHOWN.

this type of cooling more efficient. Two six cylinder Model H machines are shown, one with a close coupled body finished in golden brown, the other a regular seven passenger tonneau finished in maroon. These machines are rated at 42 horse power, and are fitted with multiple disc clutch and selective transmission, and otherwise follow the well known Franklin lines. The four cylinder, Model B, rated at 28 horse power, is also fitted with a selective transmission. This is shown in two touring car models. The G. rated at 18 horse power, is shown in a touring car and runabout model. This latter model is fitted with a progressive sliding gear. All models are provided with Bosch high tension magneto ignition, with governed spark, and with the regular Franklin carburetor; they are also provided with full elliptic springs, both front and rear.

#### THE CHALMERS-DETROIT MOTOR COMPANY,

Detroit, Mich., show both their "Thirty" and "Forty," with tonneau bodies. In addition to this, they have a "Thirty" chassis, with the cylinders and other working parts cut open so as to show the operation of the parts, the whole being driven slowly by an electric motor. There have been no changes on either of these models of anything like a radical nature. The horse power of the "Thirty" has been increased, the bore being now 4x41/2 inches; the wheel base has been increased to 115 inches, and the wheel diameter to 34 inches. The "Forty" remains the same as to mechanical details, with the exception that a magneto is now included in the regular equipment. However, the wheel base has been increased to 122 inches and the wheels to 36 inches.

#### THE OLDS MOTOR WORKS,

Lansing, Mich., have on exhibition a runabout, a six cylinder "Limited." The peculiarity of the so called "Limited" is the use of 42 inch wheels. They also show a six cylinder, seven passenger "Limited," and a close coupled four cylinder. In addition to this they show a six "Limited" polished chassis, and also their new four speed gate change transmission, which is used on all 1910 models. On this year's models they are using a carburetor of their own design, which is of the annular float chamber type, with auxiliary air valve. A special feature of this carburetor is the method of adjusting the needle valve, which allows of very fine adjustment. Bosch dual ignition is used on all models. A minor feature is the use of a petcock, with standpipe near the carburetor, which allows of drawing small quantities of gasoline for priming the motor, cleaning the hands or small parts, etc., and also for testing the condition of the pressure feed system.

#### THE PENNSYLVANIA AUTO-MOTOR COMPANY.

Bryn Mawr, Pa., are showing one seven passenger touring car, with 36 horse power, 434x51/4 inch four cylinder motor; one five passenger touring car, with 20 horse power, 41/4 x41/4 inch four cylinder motor, and one six cylinder chassis, with a 54 horse power, 434x51/4 inch motor. The cylinders of the several models are cast in pairs, with valves in the head operated through rocker arms from separate cam shafts on either side of the motor. The Bosch dual system of ignition is used on all models. The cooling is effected by a gear driven gear water pump, a belt driven fan and the radiator. Lubrication is assured by a pressure feed system. The clutches used are leather faced cone, with cork inserts and ball thrusts. The three forward speed selective type transmission is used on each different model. The front axles are I section drop forgings, while the rear are full floating. The brakes are internal expanding and external contracting, operated in the usual manner. The wheel base of the 29 horse power is 110 inches; weight, 2,300 pounds; the 36 horse power has a 114 inch whel base and weighs 3,000 pounds. The transmission on all cars is placed on the rear axle.

# THE HUDSON MOTOR CAR COMPANY.

Detroit, Mich., are showing two styles in their runabouts, but using the one chassis for both. One style is equipped with an oval gasoline tank attached back of the seat and the other with a single rumble seat at the rear. The motor is a 20 horse power one with the cylinders cast en bloc, and has 334 inch bore and 41/2 inch stroke. with the valves all on one side. The exhaust header and inlet manifold are separate castings and are free from sharp angles. In the chassis of this model, which is also being shown, can best be seen the arrangement of the leather faced cone clutch, with its slip springs underneath, and the three forward speed selective transmission. The lubrication might be termed a flooding system, as the oil level in the splash basins is kept constant by means of a plunger oil pump. Cooling is effected by means of a liberal sized centrifugal pump, fan and vertical tube radiator. Jump spark ignition with dry cells and coil is used, while provision is made for installing a

magneto. External and internal brakes act on rear wheel drums. The wheel base is 100 inches and the weight 1,700 pounds.

THE OVERLAND AUTOMOBILE COMPANY, Toledo, Ohio, show two types of body on their Model 38 chassis, one a runabout and the other a touring car. The motor is a four cylinder, cast singly, with valves on the same side, of 334 inch bore by 41/2 inch stroke. Ignition is by Remy magneto. The transmission is of the two speed and reverse planetary type, but the method of control is characteristic of the Overland, all three speeds being controlled by two pedals. The wheel base is 102 inches, and the tires are 32x31/2 inches. They also show their Model 40, the main characteristics of which are the same as those of the 38. However, the motor has been enlarged to 41/4x41/2 inches, and the wheel base lengthened to 112 inches, while the tires are 34x31/2 inches. They also show their Model 42 touring car, which is built on standard lines, with a three speed selective gear and a cone clutch with cork inserts. The motor on this car is 41/2x41/2 inches, the wheel base 112 inches and the tires are 34x4 inches.

THE GREAT WESTERN AUTOMOBILE COMPANY, Peru, Ind., are showing but one model, and that the Great Western "30," a five passenger car. They are also showing a cylinder with a part cut away to show the water jackets and the valve chambers; also a crank shaft showing its five main bearings, together with the clutch spring and thrust washer, and the lower portion of the crank case, with its oil pump for circulating the oil from the lower reservoir to the splash basin for maintaining a constant oil level. The cylinders on the Great Western motors are cast separately, with the exhaust in the head and the intake on the side. The exhaust valves, which are held in cages, are operated through rocker arms, the intake through push rods, and both are operated by the same cam shaft. A cone clutch and selective, three forward speed transmission are used, with a semi-floating type rear axle. The clutch has a composition covering, with a ball thrust releasing yoke. Ignition is by jump spark, magneto and dry cells, using a single set of spark plugs. The wheel base is 112 inches, with 34x3½ inch tires. Weight, 2,200 pounds.

#### CARTERCAR COMPANY,

Pontiac, Mich.—At the Cartercar booth five cars were shown. Two sizes of motor, the 25 horse power and the 30-35 horse power, are used, both four cylinder. With the smaller motors the natural circulation is used, but the larger motors are equipped with a centrifugal pump. The larger vehicles have a 110 inch wheel base, with 4 inch tires, while the others have a 100 inch wheel base with 3 inch tires, and all wheels are 32 inches. One of the vehicles shown is a taxicab. On a number of the cabs two cylinder motors are used. Very few changes have been made over last year. Magneto and gas lamps are included in the

equipment. The shifter bracket has been somewhat lightened and improved and the fibre or paper friction ring has been made sectional, so it can be removed and a new one substituted without taking down the drive shaft. The transmission is of the friction type, and the driven wheel is 20 inches in diameter, giving it a large leverage over the work to be done. The chain from the driven shaft is encased in an oil and dust tight case so that chain runs in oil, and it is, perhaps, the only car with chain as carefully encased as gears. The makers claim that a chain under such protection does not wear nor stretch.

#### COLE MOTOR CAR COMPANY.

Indianapolis, Ind.—These cars have cylinders cast separately, four of them making a 30 horse power motor. The valves, carburetors and exhaust are on the left side. The splash system of lubrication is used. Ignition is double, by magneto and battery. A Brown & Sharpe transmission, with selective rocker shifting lever, is attached to the engine case in such a manner as to fully enclose the flywheel. This makes a very strong arrangement, neat and clean, but the flywheel is of rather less diameter than usual. Another feature of interest is the mounting of the full elliptic springs on the rear axles by the use of rockers so the rear axle torsion is not taken by the springs. Distance or radius rods are provided, with springs on their front ends under compression, so that any twisting of the rear axle tends to shorten the springs, and they in turn tend to restore the axle to its normal position. To allow for the movement the slip joint in the propellor shaft has some 4 inches of length. The emergency brake is connected with the clutch so that application thereof pulls out the clutch. The rear axle is floating and the wheel base is 108 inches.

#### F A L MOTOR COMPANY,

Chicago, Ill.—The Falcar is claimed to be a new but standard construction wherein unusual features have been avoided. The horse power is 30, and the cylinders are cast in pairs, with 41/4 inch bore and 41/2 inch stroke. The valves are large, and at one side of the cylinder. Lubrication is by splash, with pump to maintain the level. Magneto and batteries are supplied for ignition. The clutch is conical, with a surface of asbestos composition. The transmission has ball bearings, while the running gear is ball and roller bearing. The steering gear is adjustable for wear. The wheel base is 110 inches, and the wheels are 34 inches in diameter, with 34 inch tires. The lighter rigs have 31/2 inch tires, but the heavier ones 4 inch, all quick detachable. The rear springs are three-quarters elliptic, and the speeds go up to 50 m. p. h. The tank capacity is 17 gallons. The brakes are equalizing, the service brake being lined with Thermoid, while the mergency brakes have metal to metal surfaces. The front axle is I beam. A button is provided for

starting on the switch. A roadster, two touring cars and a town car are made.

#### JEWEL CARRIAGE COMPANY,

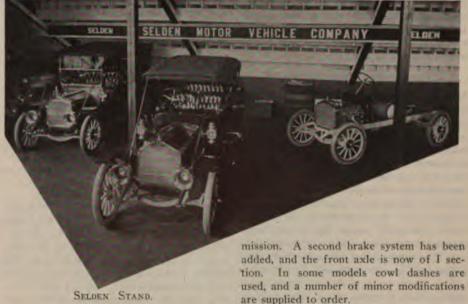

Cincinnati, Ohio,-This car is of 40 horse power, with four cylinders cast in pairs. The valve chambers and water jackets are integral with the cylinders. The bore is 41/4 inches; the stroke the same. The circulation is natural, with large tubular honeycomb shape radiator. A large, easily adjusted fan is provided. The splash system of oiling with pump circulation is used. A foot accelerator is provided in addition to the hand throttle. The clutch consists of five plates, of which two are bronze with cork inserts to easily take up the load. The springs are three-quarter platform in the rear. The front axle is I beam, and all wheel bearings are roller type. The wheel base is 115 inches, while the tires are 34x4 inches. The transmission is hung midway of the frame, with one universal joint between it and the engine and two on the propeller shaft to the rear. A special feature is a blind hinge to the hood, which makes it rain and wash water tight, and so protects the magneto and engine parts.

#### THE BRUSH RUNABOUT COMPANY,

Detroit, Mich., have on exhibition a racing car, with a reputed speed of 45 miles per hour, known as D-26; one regular runabout, D-24, and a double rumble seat, four passenger car, D-30. The racing car is the standard chassis, with a higher gear and an oval copper gasoline tank secured back of the seats. The seats are set further back to give greater rake to the steering gear. The improvements over the previous well known models are as follows: A 6 inch longer wheel base, more graceful and rakish lines, Mercedes type radiator, new selective control, universal coupling propeller shaft, improved commutator, multiple disc, low and reverse clutches, transmission control levers entirely housed and oil tight, and a more quiet muffler. The motor in these cars is a 10 horse power vertical single cylinder, with 4 inch bore and 5 inch stroke, placed under the hood with three point suspension. The transmission is of the internal gear type, with multiple disc clutches. The cooling is effected by thermo-siphon action, together with the radiator above mentioned. The frame is of selective wood. The spiral springs are located at the extreme corners of the car. The brakes are internal expanding in the rear sprocket hubs. The drive is through jack shaft and chains to rear wheel sprockets. The wheel base is 80 inches.

### THE COLUMBUS BUGGY COMPANY,

Columbus, Ohio, show their gasoline line, which includes their 7-A runabout, equipped with left hand control. The wheel base is 100 inches long, and the tires are 32x31/2 inches. The motor has 4x4 inch cylinders, cast in pairs, with all valves on the same side. Cooling is by thermo-siphon circulation. Ignition is by a dual magneto and battery system. Lubrication by a circulating splash system, with sight feed on dash.

SELDEN STAND.

A leather faced cone clutch is employed with a three speed selective, gate change gear. They also have their 6-B touring car on exhibition. The general features of this car are the same as the 7-A, except as regards dimensions and that a right hand control is used. The wheel base is 117 inches, and the tires are 34x31/2 inch front and 34x4 inch rear. The motor is 41/2 inches square. A rather interesting minor feature of both cars is a funnel carried on the radiator. When the filler cap is removed the funnel, which is carried inverted on the filler pipe, can be removed and placed in position thereon. The mouth of this is elliptic in form, thus allowing one to pour water from a bucket into the radiator with ease. When the funnel, which is a casting of polished brass, is replaced in its normal position on the radiator its use would never be suspected. Another feature of this make is the equipment of all models with electric lights and a 100 ampere hour storage battery for running them.

## STREATOR MOTOR CAR COMPANY,

Streator, Ill.-The Halladay Model 40 exhibits a few changes over last year. The wheel base has been lengthened 5 inches, and the wheels have been increased to 36 inches. To fit these changes the bodies have been made longer and more roomy, the frame has been raised at the rear end and the body sides cut into to make room for the fenders. By these changes a low hung, easy riding body is secured, and yet the road clearance has been maintained. Annular bearings have been fitted to the transmission, and the control levers are now of the rocking, selective type. The use of annular bearings all around is new, and the universal joints are fitted with grease cases which lubricate and exclude dust. The Model 30 is new, but is simply a reduction in size of the larger car. In the Model G a number of changes are found, such as larger radiator and water jacket capacity, larger and improved valve design and an additional speed to the trans-

# W. H. M'INTYRE COMPANY,

Auburn, Ind .- Four models of the McIntyre are shown. Of these three are built on the same chassis and differ in the bodies only, being for two, four and five passengers, respectively. These have 112 inch wheel bases, and the wheels are 36 inch, with 31/2 inch tires, but an option of 37x 4 inch tires is given at a cost of \$50 extra. The motors are T head type, with large valves, and a bore and stroke of 41/4 and 51/2 inch, respectively. The cylinders are cast in pairs and the motor is rated at 40 horse power. Double ignition is fitted, one set of plugs being fired by the battery, the other by the magneto. The clutch is an inverted cone, with leather face and cork inserts. The steering is adjustable for wear. The rear axle is of the full floating type and the front is an I beam. The lubrication is by pump to the crank case and splash lubrication therein. A small runabout at a moderate price is also shown. This has a two cylinder opposed motor in front and planetary transmission with shaft to the rear. It can also be furnished with chain drive if preferred. In this car the circulation is natural and the motor cylinders are 43/4×43/4 inches. The base is 90 inches and the tires are 30x3 inches.

# THE BLACK MANUFACTURING COMPANY,

Chicago, Ill., are showing three styles of the "Black Crow," one roadster, one toy tonneau and one surrey-all on the same chassis. The cylinders of the motor are cast separate, with the valves on opposite sides and operated by separate cam shafts. The bore is 33% inches, with 41/2 inch stroke. Lubrication is by self contained constant level splash system in connection with a gear driven pump. The clutch is of the multiple disc type, running in oil and working in connection with a three speed selective sliding gear. The radiator is of the honeycomb type, and the circulation is by thermo-siphon action. The rear axle is full floating type, while the front is tubular.

The brakes are internal expanding and external contracting, operated by the usual method of pedal and hand lever. The wheel base is 107 inches, with 32 inch tires. The weight is given as 1,840 pounds.

#### KNOX AUTOMOBILE COMPANY,

Springfield, Mass., are showing one Model R, five or seven passenger touring car, one Model R tonneauette and one polished power plant with one cylinder head removed and on exhibition, showing the valve arrangement. The only changes of note are the crank case and yoke, which carries the transmission. These were formerly integral, but the yoke is now separate and bolted to the case. Another change is in the water circulating pump, this having been changed from a gear pump to a centrifugal one. The transmission is of an entirely new design and is very compact. One feature of this transmission is that the shaft bearings are only 5 inches apart, thus making it very rigid. There is no telescoping hollow shaft employed, nor are there any nuts, bolts or cotter pins inside the transmission case. The clutch is of the three plate type, encased in the flywheel and fitted with cork inserts. The motor used in these models is a four cylinder, with cylinders cast separately, with both valves in the head and operated through rocker arms from a single cam shaft.

#### AUTOCAR COMPANY,

Ardmore, Pa., show one Type 22, five passenger touring car, one closed 11/2 ton delivery wagon, and one 11/2 ton open delivery wagon. The touring car is shown in deep Brewster green, which is their standard color. It has a four cylinder, water cooled motor with cylinders cast separate and the valves all on one side. One feature of this motor is the use of hand hole plates on the sides of the crank case. Many manufacturers do not seem to consider these necessary, while car owners complain because they are not there. The delivery wagons have double opposed motors of 43/4 inch bore and 41/2 inch stroke, with the valves on the upper side of the cylinder. The motor is placed crosswise of the frame in front and used in connection with a clutch and sliding gear transmission. All the cars are equipped with the well known Autocar floating ring clutch, consisting of a bronze ring with cork inserts.

### BUCKEYE MANUFACTURING COMPANY,

Anderson, Ind., are showing one Model 36, five passenger Lambert, in deep red finish and one Model 36 chassis. A belt running from the flywheel of the motor to an electric motor stayed to the floor keeps the motor and transmission in operation. Little or no change seems to have been made from former models. One feature, however, that strikes one on this car is the use of a Wilkinson mechanical motor starter, which is operated by a pedal resembling the brake pedal. When desiring start the motor one simply presses this

pedal forward and the motor is turned over. With this contrivance it is impossible to become injured by back kicking. The friction drive of the Lambert is too well known to require description. The motor is four cylinder, cast en bloc with 4½ bore and 4½ inch stroke. The valves are all on one side, and operated by a single cam shaft. The cooling is by a round tube radiator and fan. The wheel base is 110 inches. The Wilkinson starter comes as a regular equipment on the Model 36, but is an extra on all other models.

#### THE JACKSON AUTOMOBILE COMPANY,

Jackson, Mich., show a Model 50, seven passenger touring car, the extra seats being furnished for \$30; a Model 40, five passenger touring car, and a Model 30, five passenger touring car. Each of these several models is finished in black, and presents a very pretty appearance. All are four cylinder, with the same general construction. The motors have twin cylinders, with the valves inclined at 45 degrees in the cylinder heads and operated by an overhead cam shaft. A unit power plant is used, with self contained oiling system. The motor is water cooled, circulation being by the thermo-siphon system. The transmission housing is incorporated in the unit power plant. The multiple disc clutch runs in oil. There are three forward speeds, operated selectively. Ignition is by Splitdorf magneto and batteries through a single set of spark plugs. The "50" has a 434x434 inch motor, the "40" a 41/2 x 41/2 inch motor and the "30" a 4x4 inch motor. The respective wheel bases are 120 inches, 110 inches and 105 inches.

## PETREL MOTOR CAR COMPANY,

Milwaukee, Wis.-The Petrel cars are made in three styles, the touring car, a toy tonneau and a roadster, all built on the same chassis. The seats are low and the steering post is very flat, making the front of the vehicle quite long. The side lights, usually on the dash, are carried on the sides of the seats. The brake and gear shifting levers are quite short and not greatly in the way in mounting from that side of the vehicle. The wheel sizes have recently been increased from 32 inches to 34 inches, and 31/2 inch tires are used. Magneto and searchlights are included in the equipment. On the roadster a fuel tank holding 20 gallons is provided. The friction drive has adjustable springs to hold the discs in contact, but for emergency work a pedal can be used to increase the pressure. This preverts the operator carelessly setting the frictions together so tightly as to throw unnecessary wear on the bearings and require unnecessary power.

#### RENAULT FRERES SELLING BRANCH,

New York, show three models, including a 12-16 horse power chassis equipped with a touring roadster body. This has a wheel base of 116 inches, and the tires are 875x105

mm. front and 880x120 mm. rear. The cylinders are 31/4x41/4 inches. They also have a 14-20 horse power touring car on view. This latter has a wheel base of 120 inches, the tires being 875x120 mm. front and rear. The motor is 33/4x41/4 inches. This latter is equipped with a four speed gear. Besides this, they also show a 20-30 horse power limousine. This latter model has a wheel base of 128 inches and 920x120 mm. rear and 915x105 mm. front tires. The cylinders of this macnine are 4x53/4 inches. This model is also equipped with a four speed gear, and in addition with the Saurer pneumatic self starting device.

#### THE SULTAN MOTOR COMPANY.

Springfield, Mass., have on exhibition a light touring car and a town car. This chassis is especially designed for taxicab work to meet the requirements of the Scotland Yard authorities. The most striking feature is the completely removable power plant, the radiator, motor and transmission being mounted with the dash on a subframe, which may be disconnected from the machine and removed inside of thirty minutes. The motor is 3x43/8, cast in pairs, with all valves on the same side of the head. A Bosch magneto with fixed spark is used for ignition. Cooling is by thermosiphon circulation. The carburetor is arranged so that the mixture can be controlled from the dash, and high gasoline economy is claimed. The clutch is of the disc type, and the transmission of the gate change, selective type giving three speeds and reverse. The wheel base is 97 inches, and the tires are 32x31/2 inches.

#### MOLINE AUTOMOBILE COMPANY,

Moline, III.—The Moline cars have been changed very little for the coming year. The Model M touring car wheel base has been brought up to 110 inches from 107 inches. It may be used as a touring car, a roadster or even a business wagon by changing the body rears, thus meeting the needs of practical people fully. The power of the motor has been increased by making the bore 4 inches instead of 37% inches, the stroke remaining the same, 41/2 inches. For the coming season the magneto equipment is included in the regular equipment; gas lamps are likewise included. Natural circulation is used, and a very large radiator. A special feature is the mounting of the flywheel in between the arms of the frame of aluminum, which carries both the motor and gear case.

#### THOMAS B. JEFFERY & CO.,

Kenosha, Wis.—The Rambler exhibit includes three cars and a chassis. While few changes have been made, some are to be seen and are worthy of notice. The 45 horse power car uses an expanding clutch of special design instead of the cone clutch. The magneto has been set further forward to increase accessibility. The bodies are more commodious than heretofore. Spare wheels are fitted to all cars, as in the past

One of the special features is the fitting of the wheels to a square taper rear axle instead of to square straight stubs. This is a matter of durability particularly, for it permits adjustment, and the wheels may be kept free from looseness permanently. The, 34 horse power car is now fitted with magneto and battery ignition. It also has full elliptic springs instead of semi-elliptic. On this car the wheel base has been shortened from 112 inches to 100 inches, for greater handiness. A neat little fitting, which adds comfort and safety, is the placing of the horn bulb at the elbow with the support behind, so the horn may be blown by a slight movement of the elbow. The offset crank and the mounting of the transmission on the front end of the torsion tube are features worthy of notice.

#### STUDEBAKER AUTOMOBILE COMPANY.

South Bend, Ind.—At the booth bearing this well known name are several exhibits, the Studebaker limousine being new, as is the Flanders "20." This latter is particularly interesting, because of the price and the quantity which will be made before another year rolls around. It has four cylinders in block, with bore of 35% inches and stroke of 334 inches. The valves are all on one side, with a single cam shaft to operate them. A pressed steel cover closes a large opening in the water jacket on the head of the engine, rendering cleaning easy and freezing not dangerous. The valves are of 178 inches diameter and guided by removable bushings. The cams and valve lifters are ground to size, and a fibre block deadens noise. The clutch is of the inverted cone type, faced with leather. The noticeable feature of assembling is the unit idea. Thus the motor, with magneto, pump, carburetor, radiator, dash and steering gear, are all carried on a tubular sub-frame as a single unit. Four bolts permit the removal of this and the substitution of another. The transmission is on the rear axle, and ball and roller bearings are provided for the wheels. The body types are limited to two.

#### SELDEN MOTOR VEHICLE COMPANY,

Rochester, N. Y.—This car is shown in two models and a chassis, and is fitted with magneto on all models, instead of on part, as last year. The engines have been made more powerful by using larger cylinders. The transmission is of different manufacture, but with the same number of speeds. The timer is now on the end of the cam shaft, and the valves are on the left side of the engine instead of on the right. The belt for driving the fan has been brought to the right side instead of the left. The motor and transmission are carried on a sub-frame to avoid twisting strains. Four unit coils are used this year. The principal difference is the reversal of the engine with respect to the location of its main parts. The brakes are equalized, the spring bolts have grease cups, and the pedals are adjustable. Special attention is called to the torpedo body as of new design, and affording protection to the passengers from dirt and air resistance.

#### SPEEDWELL MOTOR CAR COMPANY,

Dayton, Ohio, show one Model 10-H roadster. with semi-racer torpedo body, with large oval gasoline tank back of the front seat and an artillery rear seat: one Model 10-C four passenger toy tonneau; one Model 10-F touring car, and a polished chassis. All these different bodies are fitted to the standard 50 horse power chassis, which has a four cylinder, water cooled motor, with the cylinders cast in pairs and all valves on one side. The cylinders have 5 inch bore and 5 inch stroke. A leather faced cone clutch is used in connection with a selective. three speed transmission. The rear axle is a one piece drawn steel tubing, split and shaped in the centre to admit the differential casting. The wheel base is 1211/2 inches and 36x4 inch tires are used.

#### HUPP MOTOR CAR COMPANY,

Detroit, Mich.-In this car are several changes of interest. The cone clutch has been replaced by a multiple disc, one having nine saw steel discs running in an oil bath in the gear case. The oiling system has been replaced by one which is positive in action, but is regulated by a connection with the throttle so that turning on more power insures that the engine gets more lubrication. It is well known that an engine running light is likely to smoke, and this arrangement not only prevents this, but effects economy of oil. The radiator capacity has been increased by a double row of tubes, and by an auxiliary tank of larger capacity. The drive ratio is now 4 to 1 instead of 31/2 to 1, an improvement for most American roads. The drive shaft has a ball bearing at the rear end to take the thrust and strain. The steps are further forward, with greater convenience in mounting, and are carried by two brackets instead of one. The front axle is I beam section instead of tubular. The fuel tank is now an oval cross section, with the longest diameter vertical.

## INTERSTATE AUTOMOBILE COMPANY,

Muncie, Ind.—The Interstate cars have been increased in size, and to meet the increased size by increased power the cylinders have been bored 41/2 inches instead of 41/4 inches. and have 5 inch stroke. The wheel base has been extended from 112 inches to 118 inches. This permits of a longer body, with more room, both front and back. clutch action has been improved, and the capacity increased by using sixty-three steel discs of tempered saw steel. Where formerly full elliptic springs were used now three-quarter elliptic are used on the Forty. The engine valves have been made larger. In these cars the transmission is rigidly carried at the front end of the torsion tube which surrounds the shaft, and the transmission frame is pivoted to the cross member of the main frame with only one universal joint between it and the engine. The main frame is reinforced where this cross member attaches, to make it able to carry the driving and reversing strains without sagging.

#### THE WHITE COMPANY,

Cleveland, Ohio.-While the White steamer is being sold in greater numbers than ever, the company are now in position to meet calls for a gasoline car, and particularly to meet that class of buyers who think that because the maker has but one kind which he wishes to sell, some other kind must be better. They offer this year a gasoline car. new to many, and embodying some interesting features. The cylinders, four in number, are cast in block, and are of 33/4 inch bore by 51/8 inch stroke. This is longer stroke in relation to bore than common. The makers have particularly aimed at simplicity and simple appearance. The wiring consists simply of four short wires from the distributor in the magneto to the four plugs, and two small wires to a switch on the dash. The water piping is unusually short, and the oil pipes are few in number. The inlet and exhaust pipes connect with passages forming manifolds in the cylinder casting proper, so they are less prominent than usual. Both the engine and the transmission are suspended at three points, and the transmission gives four speeds ahead, with direct drive on the third. The wheel base is 110 inches.

#### THE RAPID MOTOR VEHICLE COMPANY,

Pontiac, Mich., show a 5 ton, 60 horse power truck; one 3 ton, 45 horse power truck; four 2 ton trucks, two I ton trucks; one two cylinder, twelve passenger, 30 horse power sightseeing car; one four cylinder, 45 horse power, twenty passenger sightseeing car; one two cylinder, 24 horse power ambulance, and the I ton truck which went through the recert Glidden Tour and climbed Pike's Peak. The motors in the 5 and 3 ton trucks are four cylinder, with the cylinders cast in pairs, with the valves all on one side. The 5 ton motor is 51/2 inch bore and 61/2 inch stroke, while the 3 ton has 434 inch bore and 51/2 inch stroke. In the 3 and 5 ton trucks multiple disc clutches are used, with selective three forward speed sliding gear transmissions. The propeller shaft from the transmission connects with the jack shaft differential, and final drive to the rear wheels is by sprockets and chains from the jack shaft ends. The 2 ton truck and the 1 ton truck are nearly the same. except for a slight difference in wheel base and a one-quarter inch larger bore in the 2 ton truck. The motors used are double opposed, and on the I ton are 5 inch bore and 5 inch stroke, and on the 2 ton 51/4 inch bore and 5 inch stroke. Except on the two larger trucks the transmissions are planetary, with chain drive. The ambulance is very conveniently arranged, with stretcher for the injured or sick, seats for the attendants and lanterns and emergency medicines.

#### ACORN COMMERCIAL CAR.

This commercial car is not new, having been on the market for two years, but has not been shown at auto shows. It has a two cylinder opposed motor with shaft extended well to the rear. This shaft carries two small wide face friction pinions. A jack shaft across the car carries two conic faced discs, having three steps each, These may be separated to permit shifting the driving pinion to another step and then closed to give the proper driving friction. When driving, the contact is that of a perfect rolling cone, so there is no loss by slipping or unequal travel of the surfaces. as in most friction drives. There are three steps or surfaces on the large driven discs. providing three speeds forward. The reverse driving pinion can be pulled into place at the other faces of the discs to get a reverse direction. Since the driving pinion is between the driven discs these latter travel in opposite directions, and the motion of one is reversed by a pair of spur gears near one side of the chassis. Side chains carry the motion to the rear wheels. The centrol is on the left side.

# Electric Vehicles.

THE WAVERLEY COMPANY,

Indianapolis, Ind.—At this booth are to be seen three models. The 74 is an electric stanhope, especially adapted to doctors' use. It has a wheel base of 731/3 inches and a width of seat of 41 inches. The wheels are 32 inches diameter, and 3 inch front and 31/2 inch rear tires are fitted. These may be either solid or pneumatic. It is claimed that the new Waverley electric equipment is light enough to be carried practicably on air tires, and built strong enough to be safely and durably carried by solid tires. In all these cars an interlocking controller is used, which makes it impossible to accidentally do the wrong thing. Thus the switch key cannot be inserted if the power is turned on, but the power lever must be in neutral position first. Likewise it is not possible to reverse when the power lever is in full ahead position. This little precaution prevents accidents, such as have happened in the past by changing the direction of the current so suddenly as to turn the vehicle over backward or do some similar damage.

THE BABCOCK ELECTRIC CARRIAGE COMPANY are showing a gentleman's roadster, one victoria phaeton, a four passenger coupé and one runabout, especially designed as a doctor's car. These cars are all supplied with either steering wheel or lever guide, except the gentleman's roadster, which comes only with steering wheel. The gentleman's roadster is designed along the lines of a gasoline runabout, even to the filler cap at the top of what to all appearances is the radiator. This car has a forty-two cell battery divided between the front and back, and it is claimed to be able to ain a speed of 25 miles per hour. Each

of the other cars is equipped with a thirtysix cell battery, which is divided to equally distribute the weight. The gentleman's roadster has semi-elliptic springs in front and full elliptic in the rear, while the other cars have full elliptics all around.

#### WOODS MOTOR VEHICLE COMPANY,

Chicago, Ill,—The Woods electric vehicles have been built with special regard to practically everyday use, and so such features as solid tires are almost always used, the standard equipment including these in all cases. The same holds true of the battery, which is of forty cells instead of a smaller number less able to stand long hard service. The bodies are specially roomy, and the seats are claimed to be the widest used in any standard auto, measuring 46 inches. The motor is also believed to be larger than used on other electrics to ably carry the large body and battery. All of these vehicles are fitted with double chain drive, which secures flexibility, and annular ball bearings are used throughout. Four speeds forward are provided, which permits suiting the gearing to the work and power. Two coupés and two victorias are shown, one of the coupés being hazel and brown in color with dark brown trim, while the other is all black, with silver trim upholstered with gray and whipcord.

#### THE COLUMBUS BUGGY COMPANY,

Columbus, Ohio, besides their gasoline line, also exhibit two electrics, both of which are fitted with left hand control. One of these is the Model 1000, fitted with victoria top, and the other is the 1202, a coupé model, with enclosed control. A six speed controller is used this year instead of a five as formerly.

#### THE RAUCH-LANG CARRIAGE COMPANY,

Cleveland, Ohio, show one large extension, forty cell coupé, one roadster designed after the style of a gasoline roadster, and one victoria. The coupé has an 81 inch wheel base, and has, it is claimed, an average mileage of 75 per charge. The roadster has thirty cells, and gives an average of 65 miles per charge, and a speed of 25 miles per hour. It has steering wheel guide instead of lever, and has an 82 inch wheel base. The victoria has a wheel base of 76 inches. All models are equipped with electric brakes. The respective weights are 2,800 pounds, 2,000 pounds and 1,050 pounds.

# BAKER MOTOR VEHICLE COMPANY,

Cleveland, Ohio.—These well known electrics are shown in several styles and a chassis is mounted with its wheels off the floor, so it can be run to show the ease of operation. While in general these vehicles have been continued as in the past, the four passenger, extension front coupé is new and has been put out to meet a demand for a vehicle that can be driven from the inside. It is about 3 inches longer than similar chasses heretofore, and very commodious. The Model S runabout is neat, trim and speedy, being capable of

25 m. p. h., and well suited for business men. The roadster is on gasoline car lines, and has a speed of 30 m. p. h. It and several others have wheel steering, with the controller lever on the post, and are easily handled.

## Motorcycle Exhibits.

THE AURORA AUTOMATIC MACHINERY COMPANY,

Aurora, Ill., are the makers of the "Thor" motorcycle and parts, and show a line of these machines, both single and twin. equipped with both battery and magneto ignition. The distinguishing feature of these machines is the combined enclosed gear and chain transmission. They have on exhibition a new machine known as the Thor IV. This is somewhat of a departure from the regular lines. The motor cylinder and head are cast integral. This motor is guaranteed to give 4.7 horse power at the rear wheel. A special feature is the new automatic oiling device, of the centrifugal type. The motor is equipped with roller bearings on the crank shaft. Another special feature is a combined oil and battery tank. In this are carried 13/4 gallons of gasoline and 11/4 gallons of oil. When this machine is provided with battery ignition. a two unit coil is used. In this model the compensating sprocket is placed on the motor instead of on the rear wheel.

### THE HENDEE MANUFACTURING COMPANY.

Springfield, Mass., makers of the Indian motorcycle, show in all six machines, including three 234 horse power singles and three 5 horse power twins. Quite a number of new features have been adopted this year, including a new type of spring fork of the link type. The upright movable rods go up to a broad flat spring, which is used in preference to the usual type of coil spring. The main fork is now of the truss pattern. While the lubrication is on the splash system, an automatic pump driven off the crank shaft by a gear worm, which makes one stroke for about 36 revolutions of the motor, is used to feed the oil constantly to the crank case. The stroke of the pump can be adjusted. The whole device is no larger than the cam gear cover and is attached to the side of the crank case. The old hand pump is still retained for emergencies. A tubular stand is now made a regular part of the equipment of all the machines. All the twins of this make are now equipped with magneto igcition.

# THE N. S. U. MOTOR COMPANY,

New York, are exhibiting three models, a 3½ horse power single, a 3 horse power twin, and a 4 horse power twin. The 3½ horse power is equipped with what is termed an undergeared pulley; that is, a reduction is made to the belt pulley by a pinion on the motor shaft, which meshes with an internal gear on the V shaped

(Continued on page 547.)

# The Atlanta Show.

The first of the season's big national shows opened its doors at Atlanta, Ga., on Saturday last. Considering the relative newness of the Southern market it must be admitted that the industry is very well represented. The official list of exhibitors contains not less than seventy-five names of car manufacturers, which is more than have exhibitéd at any New York show for some years. In the Auditorium Armory Atlanta possesses a fine show building. Its central location and excellent railroad connections make it the natural distributing point for the South Atlantic States, and the energetic campaign for good roads and for the creation of automobile interest in that section. conducted by its leading citizens and its newspapers, certainly deserved recognition on the part of the industry.

The South does not have to pass through the same stages of automobile show development as did the big metropolitan cities of the North and the Middle West, where the earliest shows comprised only about a dozen different makes of cars each, and some cars about which the visitor was never certain whether they would actually run or not. Instead it can start with a show comprising every variety of motor vehicle, the products of a highly developed industry. That such a show is worth going a considerable distance to see by anyone at all interested in motor cars seems to be fully appreciated in the South, and judging by the attendance on the opening night the first Southern national show will be an all round success.

The plan of opening the new speedway or motordrome at Hopeville during show week and holding races there, including at least one big event every day of the week from Tuesday on, must be considered a very happy one. It gives the motor enthusiasts who come from a distance a chance of examining the principal cars now manufactured in this country, and at the same time view a series of races on a modern automobile track. That the races on the Atlanta track this week will be highly interesting may be inferred from the fact that what proved itself to be the fastest car in America the past season will there be pitted against the car which holds the world's record for speed. This should therefore prove a very strong attraction for all lovers of the sport.

The manner in which the show has been advertised deserves commendation, and the two great dailies of Atlanta, the Constitution and the Journal, deserve credit for the space which they have unstintingly given to the automobile and good roads movement during the past several months. The setting of the show and the decorations are excellent. Perhaps the only thing that stands in the way of a complete success of this Southern automobile week is the limited accommodations afforded by the hotels in Atlanta, but in this connection it is gratifying to note that the citizens and the authorities have done everything in their power to overcome this deficiency, even to the extent of suspending court sessions during the week, "because all hotel accommodations would probably be required by automobile show visitors."

# The Calculation of Chassis Springs.

In the present issue we print the second instalment of an article on chassis springs, by Messrs. Landau and Golden. From the first instalment, in our last week's issue, it

is quite evident that the manufacture of these springs at the present time is an empirical art. That is, the spring maker in selecting suitable springs for an automobile uses his judgment, is guided by the proportions of springs used on other similar chassis, and then tries and alters the springs until he finds a suitable combination. This method, it must be admitted, has led to excellent results in connection with horse carriages, and a proposal to calculate springs for horse vehicles from the modulus of elasticity of the steel, etc., would probably be scoffed at by a carriage builder. The motor industry, however, has materially changed the problems with which the spring maker has to deal. The greatly higher speed necessitates extremely sensitive springing, and the importance of light weight in a high speed vehicle makes the use of special steels almost imperative in the springs of high powered cars. The spring makers have had centuries in which to develop the carriage spring, while the automobile has progressed in a decade from a ten-mile-an-hour to a mile-a-minute vehicle, and the requirements with respect to the chassis springs have grown apace.

Carriage building is probably one of the oldest of the mechanical arts, and all its branches have been developed by cut and try methods. It was probably in connection with railroad engineering that modern engineering methods were first applied to the design of leaf springs. Most of the formulas for the calculation of leaf springs that are found in engineering handbooks, etc., were developed in connection with railroad work. The design of automobile springs involves undoubtedly still greater difficulties than that of railroad springs, for while the average speeds are not as great in the case of the automobile the amplitudes of the vibrations which have to be absorbed are far greater. That the problem of automobile spring design is susceptible of mathematical solution hardly admits of any doubt. We do not wish to be understood as claiming that any good mathematician can set to work and from the properties of steel alone design a proper set of springs for an automobile. A set of experience constants must undoubtedly first be determined by actual experiment, but after these have once been found they can be embodied in rational formulæ, which can then be used for the calculation of springs for any load and maximum speed. It is mainly these experience constants which have been lacking so far.

The article by Messrs. Landau and

Golden covers the subject quite thoroughly, and will, we are sure, be read with interest by every automobile designer and by many of the more progressive spring makers.

# Why the Carburetor Should Be Particularly Accessible.

In the struggle to attain accessibility of motor parts, which has been so successful in the main, and which has relieved the operator of a large part of the discomfort attendant upon the care of a motor car, the carburetor, it would seem, has not fared as well as most other motor elements. It is generally assumed that the carburetor should require very little attention, and that its adjustment, once perfected, should be satisfactory for long periods of time. However, in ordinary practice, carburetor troubles are rather frequent, or at least faulty operation of the motor is frequently referred to the carburetor. The recent very marked improvement in ignition apparatus has greatly reduced the attention required by this part of the equipment, so that carburetor derangements, at present, occupy a relatively larger place than formerly among the minor difficulties of motoring.

If weather conditions and fuel quality never changed, if perfectly clean gasoline were always obtainable, and if carburetor adjustments once made never worked loose or changed, there would be no real need of tampering with the carburetor. This is not to say, however, that it would be left alone by the average motorist. There are some deranged conditions of engine operation, the "diagnoses" of which are so close and difficult that an experimental change of carburetor adjustment is called for, although trial often proves that the defect lies elsewhere. The adjustments of a carburetor may thus have to be disturbed, although the adjustment may be all right. There is no doubt that wide changes of atmospheric temperature and pressure, affecting the height of the fuel level, the viscosity and rate of flow of the gasoline and the weight of oxygen per unit of volume in the entering air, do actually call for changes in adjustment. Then, too, carburetor float valves wear appreciably in service and cause changes of fuel level, lock nuts occasionally turn off and allow adjustments to become incorrect, and spring tensions vary in course of time. The circumstance which leads more frequently than any other to an unavoidable change in carburetor adjustment is the presence of foreign matter in the fuel. When dirt becomes lodged in the passage leading to the jet, by being caught under the needle valve, the natural way of removing it is to open the needle valve widely and to flush the obstruction out by "priming" or by allowing the engine to draw full charges and thus suck the dirt through the standpipe. Despite the use of chamois filters in filling funnels, settling pockets in the bottoms of tanks, separators and strainers, foreign particles are almost certain, at some time, to reach the carburetor and clog it. Dirty gasoline is still the source of a good deal of trouble, even for the most careful operators. and is the most common legitimate reason for the disturbing of carburetor adjustments.

Upon cars making use of gravity fuel feed, the carburetor is usually placed on one side of the motor at just as low a point as possible and clear the underpan. In modern cars of long wheel base, especially those with six cylinder motors and with the front seats located well to the rear (an extreme case being the six cylinder runabout), the gasoline tank under the seat is a long way from the carburetor, and when the car is ascending a steep hill, with the tank only partly filled, the gravity head supplying fuel to the carburetor becomes little or nothing. Thus the carburetor must needs be placed just as low as possible to encourage the flow of fuel. With the pressure feed system carburetor location is not restricted by any such considerations, but there is, very properly, a disinclination to employ it upon the part of manufacturers, on the ground that the complication entailed is not generally warranted.

Even though the carburetor has to be placed at the lowest available point, barely clearing the underpan, the situation would not be so bad were all adjustments capable of being made from above; but, unfortunately, a considerable proportion of carburetors have their needle valve adjustments protruding from the bottom of the vaporizing chamber. It is thus necessary to contort the hand into the dirty, oily space between the carburetor and the pan in order to turn the adjusting screw, and the operation is the more difficult because one cannot see what one is doing. A small section is sometimes cut out of the underpan directly beneath the carburetor so that from under the car the adjustment may he reached, but this is a poor remedy. One manufacturer has gone so far as to provide the needle valve stem with a small spur pinion and to mount upon the side of a carburetor a vertical shaft with a thumb piece upon the upper end and a spur gear upon the lower end, meshing with the gear upon the needle valve stem. This enables adjustments to be handily made from above. It is much better to so design the carburetor that the needle valve stem projects upwardly through the top of the vaporizing chamber, and it is believed that all carburetors should be built this way. The practice is by no means universal at present, however.

Whenever the carburetor has to be dismounted for a thorough cleaning or for any other reason, and whenever the strainer, which is sometimes placed at the entrance to the float bowl, has to be cleaned, the fuel supply pipe must be disconnected. Almost universally this pipe enters the fuel bowl at the bottom, and one works in the dark in a dirty and confined space to break the union. It would be much better were the fuel pipe permanently fastened to the fuel bowl inlet, and the union transferred from beneath the carburetor to a more accessible position.

Even the auxiliary air adjustment of some carburetors is made from beneath, and it is a very dirty and painful job to perfect the adjustment, working "out of sight," and to securely tighten the locknut by means of a wrench which will barely turn in the restricted space. There seems very slight excuse for an air adjustment so unhandily placed, but it will be found on thousands of cars.

Every commonly used adjustment should, it is believed, be brought out from the top or side of the carburetor if the carburetor is to be placed in accordance with existing practice. Where a dashboard adjustment of the needle valve or of the auxiliary air valve is provided the situation is, of course, greatly bettered.

#### Coming Events.

November 6-13—National Automobile Show, under the auspices of the N. A. A. M., at Atlanta, Ga.

November 20-21-New Orleans, La., Two Day Track Race, New Orleans A. C.

November 22—Flag-to-Flag Reliability Run, from Denver to City of Mexico.

December 29-30—Philadelphia (Pa.) Annual Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7—New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

January 8-15—New York Annual Show, Madison Square Garden, Association of Licensed Automobile Manufacturers.

February 5-12, 1910—The Ninth Annual National Show at Chicago, Ill.

February 22-26—Kansas City, Mo., Fourth Annual Show, Convention Hall, Kansas City Automobile Dealers' Association.

# Recent Tendencies in Ignition Equipment—Some New Systems.

# By Albert L. Clough.

Ignition equipments exhibiting wide diversity are to be found upon the new cars for the 1910 trade. At one time, not very long ago, it looked as though a great many manufacturers were likely to adopt the high tension magneto as the sole ignition source, and to dispense entirely with the battery, as has been done by so many of the foreign builders. This, however, has been done by only a very few car builders, as most users seem to desire an alternative system, which is at least capable of starting the motor from the seat and which is partly independent of the magneto. The dual system, in which a battery current acts through the magneto coil and distributor and a make and break upon the magneto shaft, seems to be very popular. If, as in one dual system, there is a special make and break device carried on the magneto shaft, which performs the function of interrupting the battery current only, and a special coil, the battery system becomes mors nearly independent of the magneto system than otherwise and thus a more effective safeguard against ignition failure. ability to spark at the motor by the use of a button which makes and breaks the battery circuit is a great convenience, but it is probably true that the dual system is rather frequently confounded with the double system by those who are not "up" on ignition details and more confidence placed in its "dual" feature than is actually warranted.

It is likely that magnetos capable of giving a spark by manipulation from the seat, but without the assistance of a battery, will soon be upon the market in variety, and, if this proves to be the case, there will be less incentive to use the present form of dual system, which is mainly useful for its self-starting feature and for the ability which it gives the operator to run his engine at a lower speed than that at which many makes of magneto will generate effectively.

SEAT STARTING MAGNETOS.

There seems to be considerable activity among magneto manufacturers in working out this seat starting feature. The favorite method of attacking the problem is to so arrange matters that a motion of the spark timing lever shall produce, in one way or another, a sufficiently rapid cessation of the magnetic flux enclosed within the armature conductors, to cause a discharge. Some magnetos of conventional design can be made to develop a quite reliable spark by a sudden movement of the timing device and recently a magneto of a special nonrotary type has been brought out, which makes a special claim for seat starting ability.

#### CLEARING THE DASHBOARD.

True double ignition, consisting of two absolutely separate and independent systems,

seems to be looked upon with favor by most automobile users, and is to be found upon a large fraction of the cars which are carefully equipped. Assuming that a high tension magneto is to be used for the primary system, almost universally, there is still a great deal of variety noticed in the choice of the secondary or standby system. One tendency is quite noticeable, namely, to so arrange both systems that they shall encumber the dash as little as possible. This is in line with the general movement to remove everything from the dashboard save the electrical switches and occasionally an oil telltale. The so called direct high tension magneto, which makes use of no separate "step up" coil, conforms to this tendency very naturally, as a simple switch is the only portion of the system external to the magneto itself and this takes up but little space upon the dashboard. There is no reason why the plain coil, employed in connection with the indirect high tension magneto, should not be placed under the hood and the switch only be mounted upon the dash. In fact, the only classes of apparatus which it is desirable to fasten to the dash are those which require frequent adjustment, or which must be under the constant observation of the operator. It is becoming quite customary for plain coils and even electrical apparatus which requires only very infrequent adjustment to be placed under the hood. Perfectly tight oil, water and heat proof containing cases, usually of pressed steel, are provided for this kind of apparatus, and usually some shortening or simplification of the wiring is brought about by an under the hood location.

## MULTIPLE VIBRATOR COILS.

The multiple vibrator coil system appears to be losing ground as the secondary or standby system, for it is bulky and is almost necessarily mounted on the dash, in order that the vibrators may be easily looked after. Upon many cars equipped with double ignition it is used very rarely indeed, and there seems to be an impression that "its room is better than its company." It seems to be the feeling that the standby system, considering how little service is required of it, must be unobtrusive.

As substitutes for the multiple vibrator coil arrangement various special battery saving systems are being quite widely adopted, and also the single coil and distributor arrangement. The master vibrator system is also gaining some prominence on the ground of its synchronous feature.

#### BATTERY SAVING SYSTEMS.

A great deal of skill is being expended in the development of battery saving systems. These are generally of the single make and break per ignition type, and the same circuit controlling device sparks all

cylinders, so that uniformity of timing may be secured. If the closure of the circuit is made only long enough properly to charge the coil, and is arranged so that its period is independent of engine speed, current economy is promoted and battery life increased. Such economical systems tend toward the use of dry cells. It is not uncommon to secure a mileage of 1,500 from a single set of six dry cells used in connection with such an ignition arrangement. When used as a standby system this means that in. ordinary use the cells deteriorate by age rather than use, and it is cheaper and better to put in a set of dry cells at long intervals than to maintain a storage battery, with its necessary periodical freshening charges, replenishments of liquid and so forth.' The employment of electric lights has an opposite effect as regards the choice of the battery to be installed, and tends to favor the use of the storage, which is capable of operating the lights and supplying the ignition system as well.

#### LOCATION UNDER HOOD.

The special ignition systems referred to are, many of them, intended for location under the hood, with the switch only upon the dash. Plain coils are, of course, the rule. One special type includes, in a single shaft mounted unit, the make and break, the distributor and the coil, the condenser only being separate. While mechanical means are generally resorted to for the operation of the make and break, in one system the single break per ignition is brought about electrically.

Low current consumption is, as a rule, indicative of a low rate of wear at the break points, and thus these current saving systems tend to require very infrequent adjustments. Now that the multiple vibrator coil system has lost some of its prestige, the advance into popularity of special systems of battery ignition, wherever battery systems are required, seems likely to be rapid, insuring, as most of them do, better synchronized ignition, higher current economy, less frequent attention, and reduced obtrusiveness of the apparatus.

#### SINGLE COIL SYSTEMS.

A few years ago the average manufacturer was very timid about adopting the single coil and distributor system, but now the high tension distributor has become such a familiar device upon magnetos, and as a part of successful special battery systems, that manufacturers do not hesitate to install it, with a single vibrating coil as the standby battery system, even upon the best cars. The single coil, even if placed upon the dash, takes up very little room, but there is probably very little real need of placing any secondary ignition apparatus on the dashboard, for it is used so little

that adjustments are very uncommonly required.

Carrying out the idea of the self contained power plant, it is becoming quite common to mount the stationary apparatus of special battery systems directly on the engine, the switch and battery wires being the only ones requiring to be detached if the engine is dismounted.

Certain of these special battery systems, while not employing a vibrator circuit breaker in ordinary service, embody one as a part of the equipment to be used in starting the motor from a cold condition or in "sparking up" from the seat, the idea being that a succession of sparks for a perceptible period is more effective in igniting a weak or cold charge than is the single spark. With a similar idea in view, one inventor so arranges matters that a very powerful current is allowed to pass at starting, which is reduced to a normal value after the motor is in regular operation.

#### HIGH FREQUENCY SYSTEM.

In order to do away with the objectionable features of the vibrator and still to retain whatever advantages the multiple spark system may possess, a high frequency system has been brought out. This substitutes for the usual electro-mechanical vibrator the natural wave period of a circuit containing an induction coil and a condenser. When the circuit containing this carefully proportioned inductance and capacity is broken by the timer, the discharge is of an extremely rapid oscillatory nature, and when this high frequency current is distributed to a small step-up coil, located at the plug, which is in the firing order, a high frequency discharge results at the plug gap.

This is certainly a neat manner of avoiding the use of a vibrator, by thus insuring, through the electrical characteristics of the circuit, the desired oscillation which is claimed to be exceedingly rapid and of special efficacy in firing the charge. As there is nothing about the apparatus to adjust, all parts of it except the switch are placed under the hood. This system is specially recommended by the makers for use with a low tension geared magneto, since there is no vibrator to be burned by the magneto current.

#### MASTER VIBRATOR.

The master vibrator system, which is a form of apparatus that may be regarded as intermediate between the multiple vibrator coil system and the single coil and distributor arrangement, has lately been taken up by a number of coil manufacturers and put into thoroughly reliable form. It appeals to those who desire closely synchronized ignition, but who do not care to use the high tension distributor. By careful design the master vibrator may be made to require a minimum of attention, practically none, when used as a part of the standby equipment.

GREAT VARIETY OF SYSTEMS.

This variety of battery systems is rather

bewildering, and almost anyone will find among their number one which suits his peculiar taste. While battery systems have here been spoken of in the capacity of auxiliary, secondary or standby equipment, it is not to be forgotten that any good, synchronized battery saving system which is free from the need of frequent adjustments is a close competitor of the high tension magneto as regards fitness for serving as the primary equipment. Cars using such systems are extremely satisfactory, but, never-

theless, the magneto is almost universally accepted as the logical means of primary ignition.

If the magneto is rendered self sparking from the seat, will battery ignition systems be forced into an even more secondary position than at present, or will the widespread use of electric lights and the necessity of carrying batteries of large capacity tend toward a limitation of the use of the high tension magneto and the adoption of battery ignition systems? Time only can tell.

#### The Phonendoscope.

The phonendoscope is an instrument intended to be used for definitely locating the various operative noises which are set up by a gasoline motor. Manufacturers in the work of refining their motors in point of quietness often require a means of minutely studying the sounds emitted by each operative part, as a preliminary to their reduction or elimination, and repair men and users frequently need a reliable means of definitely locating knocks or other noises which are evidences of abnormal conditions.

The ordinary physician's stethoscope has been employed for this purpose to some extent, but its indications are of a rather indefinite character on account of the fact that the sounds from several parts of the motor enter the bell and act upon the diaphragm simultaneously, giving a confused indication. The stethoscope, furthermore, is too short to allow of all parts of the motor being reached conveniently by the observer, and the bell is not of proper construction to give good results.

In the phonendoscope the usual form of stethoscope double ear pieces, lightly pressed together by a spring, is retained, but this is connected to the diaphragm box by means of two separate flexible tubes of good length. To the diaphragm is secured one end of a resonant hard rubber rod of considerable length, and the other end of this is provided with a button which may be placed in contact with any part of the motor. Sound vibrations are conducted from the motor through this rod and cause the diaphragm to vibrate, setting up sound waves which traverse the flexible tubes and the

ear pieces, and are heard by the observer. The ear pieces cut off extraneous sounds from the observer, and the diaphragm is affected only by sound waves sent out by the part of the motor with which the end of the rod is in contact.

In using the instrument the rod end is held by the operator or his assistant against that external portion of the motor which is in the closest proximity to the working part the operative sounds of which are to be studied.

The accompanying illustration shows the recommended positions of the rod for the detection of various motor noises, the list being by no means complete:

Position A locates piston ring and piston pin knocks.

Positions B and C locate loose pistons and premature explosions.

Position D locates noisy push rods and defective cams.

Position E locates worn valve guide of valve seating heavily.

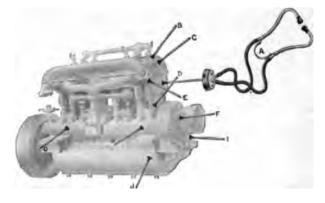

Positions F and I locate tightly meshed worn or out of true gears.

Positions G and H locate noisy cam shaft bearings.

Position J locates loose connecting rod tips, main bearings and crank shaft end play.

The phonendoscope is to be had from the American agents, Messrs, G. P. Pilling & Son Company, corner Arch and Twentythird streets, Philadelphia.

According to official statistics Roumania imported automobiles to the value of 1,523-622 francs in 1907, as compared with 1,170-658 francs in 1906.

SHOWING USE OF THE PHONENDOSCOPE.

# Calculation of Chassis Springs—II.

# By David Landau and Asher Golden.

#### DEFLECTION AND FLEXIBILITY.

We will discuss first the subject of deflections and make a critical examination of some of the existing formulas for finding this factor. We have looked up a great deal of the available literature on this subject and have failed to find universal agreement among engineers as to the correct expression for the deflection. There are a number of good formulas, it is true, but these are of little value unless used in connection with some constant or correction factor derived from actual experience with a great number of springs.

The total deflection under a given load, or the deflection per unit load, which we call the flexibility, is the factor which determines the "softness" or the "hardness" of a spring. If the flexibility is too low the spring is too "hard" and vice versa. Another, perhaps better, way of expressing this characteristic is by what Lanchester calls the "suspension period." This he defines as the time required for the spring to make one complete oscillation. The spring is "hard" if the period is too short and vice versa.

With certain restrictions the spring may be treated as a pendulum. The time (T) in seconds required to make one complete oscillation of a simple pendulum is expressed by

$$T = 2 \pi \sqrt{\frac{l}{g'}}....(1)$$

where *l* is the length of the pendulum in feet. This holds true, provided the string by which the weight is suspended is inextensible and weightless, the arc of swing is small, and there are no friction losses.

If we take a spring, Fig I, supposed to have no inertia, and support at the point A a particle so that the stress exerted in the spring by virtue of the action of gravity on the particle keeps the spring in equilibrium when deflected a distance d, then it can be shown that the motion of such a particle is a simple harmonic, and its period is

$$T = 2 \pi \sqrt{\frac{d}{g}} \dots (2)$$

which is the same as equation (1).

This expression holds true for a spring consisting of a single leaf where there is no friction. Where more than one leaf is employed friction plays an important part in tending to damp the oscillations, and must therefore be taken into consideration. If  $\mu$  be the coefficient of friction between the leaves, then equation (2) may be more correctly written

$$T = 2(l + \mu) \pi \sqrt{\frac{d}{g}} \dots (3)$$

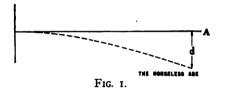

The following table shows the number of complete oscillations per minute. The figures in column 1 are computed from equa-

tion (2) and those in column 2 from equation (3):

Deflection	Complete Oscillations			
in	Per Minute.			
Inches	Column 1. Column 2.			
1	188 157			
1½	153 127			
2	133			
21/2	120 100			
3	108 90			
3½	100 84			
4	94 78			
4½	88 74			
5	83 70			
5½	80 67			
6	77 64			

Lanchester has found that in practice an oscillation period of two-thirds of a second—that is, a frequency of 90 oscillations per minute—gives an ample degree of comfort. This corresponds to a deflection of about 4 inches, from equation (2).

Calling into operation equation (3) and assuming that under good running conditions—spring leaves properly ground and lubricated— $\mu$  is .16 to .20, we find that 90 oscillations per minute corresponds to a deflection of about 3 inches, which is 75 per cent. of that found from equation (2).

This is sufficient to make a noticeable difference in the riding qualities of the springs. But, aside from this, it seems to us preferable to work from the oscillation period rather than from the flexibility, although these terms are mutually convertible. For example, we will take for granted that a spring is to have a total deflection of 3.5 inches for easy riding and is to sustain a load of 750 pounds. This will give approximately an oscillation period of 80 to 90 per minute. The flexibility will then be

$$\frac{3.5 \times 100}{750} = .5 \text{ inch per 100 pounds.}$$

The designer is now in a position to specify the load the spring is to sustain and the total deflection desired. Or, in place of these, the flexibility. From either of these specifications—the load and total deflection, or the flexibility—the spring maker should be able to supply the proper spring.

It is seen from the above that the flexibility of a spring is inversely proportional to the load to be carried. The greater the load the less will be the flexibility. For example, for a very light car the flexibility may be as great as 1.5 to 2 inches per 100 pounds, and for a very heavy car as low as .15 to .18 inch per 100 pounds.

The question of clearance very often has considerable influence on the flexibility. The distance betwen the axle and the frame may be so short as to cause one to strike

the other unless the springs are made unduly hard. A certain load may be specified by the designer and the springs supplied to carry the load may be found too great for the clearance. The fault here rests entirely with the designer for failing to specify the clearance. The permissible deflection is also limited by the material of which the springs are made. If the material is very flexible—that is, has too great an elastic elongation—a greater number of leaves will be required to prevent the springs from settling under the load.

#### DEFLECTION.

It is important to find the deflection of a spring under a given load. There are several formulas for finding the deflection; some of these are purely empirical and are of value only when used in particular cases. They are of no value otherwise, since it is practically impossible to find suitable constants or correction factors so as to make them applicable in a general way.

The following formulas are the ones most generally used; some are based on the elastic equation of a centrally loaded beam supported at its ends; others on a cantilever with a concentrated load at its free end:

Morrison,

For semi-elliptic springs with part of leaves graduated.

In the above formulas:

L = length of the spring under load.

l = half length of the spring = L/2.

d = deflection of the spring under load.

W = total load on spring in pounds.

n = number of leaves.

t = average thickness of the leaves.

b =width of leaves.

E = modulus of elasticity in bending.

I = moment of inertia about axis parallel with the width.

P = load on one end of spring = W/2.

K = a constant = 1.2 to 1.5.

S = fibre stress (80,000 pounds per square inch).

H = free height of spring.

r = percentage of full length leaves.

In equation (4) d is the deflection in sixteenths of an inch per ton of load; b is the width of the leaves in inches; t is the thickness of the plates in sixteenths of an inch.

In equation (6) d is taken in inches per ton of load and E=16,000 tons per square inch

If in equation (5) we make p = 0, we have

$$d = \frac{6 P l^8}{E \pi b t^3},$$

which is the same as equation (2).

If in equation (1) we make W=2 P and L=2 l, we have

$$d = \frac{3 \times 2 P \times (2 l)^3}{8 E n b t^3}$$

which is the same as equations (2) and (5).

Equation (3) is the same as equations
(1), (2) and (5), except that an allowance is made for several top leaves which are all the same length.

If in equation (8) we substitute for W its equal 2 P and for L its equal 2 l, this becomes

If in equation (6) we multiply the second number by W/2,000, the value of E becomes 32,000,000, and d is then given in inches actual deflection and is the same as that given in equation (11).

If in equation (7) we disregard the constant K, introduce the factor n (number of leaves), and substitute for I its equal  $bt^3$ , this equation becomes the same 12 as (11).

We see from the above that equations (1), (2) and (5) are the same; these consider the spring as a beam supported at its ends with a central concentrated load. Equations (6), (7) and (11) are also similar; these consider the spring as a cantilever with a concentrated load at its free end.

It is immaterial which of the above six equations we apply, provided care is taken to introduce the proper constants, in which case all six will be found to give the same value for the deflection.

We will now apply equation (2) to two actual cases and compare the values found with actual measured deflections. The two springs considered were made abroad and are regarded as good suspensions; that is, they have the proper flexibility for the

loads. The characteristics and dimensions are as follows:

P = 200 kilograms = 440 pounds. l = 500 m/m = 19.7 inches. b = 50 m/m = 1.97 inches. t = 6.65 m/m = .262 inch.n = 0

E = 20,000 kg. per sq. m/m

= 28,300,000 pounds per

square inch.

Substituting in equation (2), we have

$$d = \frac{6 \times 440 \times 19.7^{3}}{28.300,000 \times 9 \times 1.97 \times .262^{3}} = 2.237$$
inches.

The actual deflection of this spring was found to be 1.89 inch.

The following example is that of a smaller spring having the following characteristics and dimensions:

 l = 450 m/m = 17.7 inches,

 b = 45 m/m = 17.7 inches,

 t = 6.35 m/m = 0.25 inch.

 n = 6 E = 28,300,000.

Making the necessary substitutions, we find d to be 1.56 inch. The actual deflection of this spring under the specified load was 1.42 inches.

Proceeding in this way, we constructed the Table I for semi-elliptic springs. The data and dimensions were placed at our found from equation (2). From the last column we have D/d = .86, or D = .86d; that is, the actual deflection is 0.86 of the calculated deflection. We can now write equation (2) as follows:

$$D = 0.86 \frac{6 P l^3}{E n b l^3} \dots (12)$$

The constant 0.86 practically represents the deficiency due to the coefficient of friction, which in the above cases should be taken at about 0.14 to 0.16; that is 1-086 The springs from which the above table was constructed had their leaves ground on both sides, and were well oiled. It is evident that if the leaves were dull the ratio of the measured to the calculated deflection would be lower than that given in the table. The constant in this case would be  $(I - \mu)$  where  $\mu$  is the coefficient of friction. We see now that we can get a very close approximation to the actual deflection by multiplying the right hand member of equation 2 by  $(1-\mu)$ ; we then have

$$d = (1 - \mu) \frac{6 P l^3}{E n b l^3} \dots (13)$$

This formula will now apply to any semielliptic spring provided we know the values of E and  $\mu$ . It must be remarked, however, that the value of d from equation (13) applies to a free spring; that is, one not secured to a spring seat, and the values of the calculated and measured deflections given in the table have a similar application.

Table I.									
Length				Average	Calculated	Measured			
Under	Load	Number	Width	Thickness	Deflection	Deflection	D		
Load.	on Spring.	of Leaves.	of Leaves.	of Leaves.	d.	D.	-1		
100)	300	7	50	6.57	56.5	48	.86

1500	650	10	6o	7 - 45	166.0	143	.862		
1500	700	11	6о	7.50	159.0	140	.878		

disposal by the Etablissements Lemoine, who consider the springs to be "good suspensions." Dimensions are given in millimeters and loads in kilograms. It may be well to remark here that all the numerical calculations and the constructions of the tables in this article were made with a 10 inch slide rule.

Referring to the last column of this table we note the interesting fact that the ratio of the measured to the calculated deflection is a constant, practically 0.86. This is sufficient to show that equation (2) will give correct results provided the second member of the equation is multiplied by some constant. This equation, as well as the cantilever equation, applies to an ideal spring; that is, one in which there is no friction between the plates. If we consider friction, it is evident that the calculated deflection will have a lower value than that

The fact that the spring is secured to a seat will not materially affect the deflection.

The deflection given by equation (6) is only two-thirds of that given by equation (2). It is seen, therefore, that the calculated value of d from equation (6) is lower than the actual deflection, a result that cannot be justified. The calculated deflection should in any event be greater than the actual. We are therefore led to accept equation (2) as being correct for theoretical deflections and equation (13) for actual deflections. But, as is pointed out above, it is immaterial whether we employ one equation or the other, provided we use the proper constant. We ourselves prefer to use equation (7), giving to K the value 1.2 to 1.5. This constant depends on the condition of the surfaces between the leaves and therefore serves the same purpose as the constant (1-4) in equation (13).

# DESCRIPTIONS OF NEW VEHICLES AND PARTS.

#### The Winton Six for 1910.

radical changes will be found in the on Six, manufactured by the Winton r Carriage Company, of Cleveland, for 1910, but many little refinements been introduced which will increase ar's merit. While the motor remains ame as before, the multiple disc clutch per cent, larger in diameter than in and with four springs requires but foot pressure for operation. The mission now has four forward speeds ad of three, a new extreme speed haveen added. A new perfected carburetor to the efficiency of the motor. The e is inswept in front to give a shorter ng radius. The springs are of ined size and are semi-elliptic all around, itting low suspension of the body. Four absorbers and four rubber bumpers now fitted. The front axle is of chanection pressed steel. The wheel base 4 inches, an increase of 4 inches. The is longer and wider, with bucket seats ard and wide tonneau doors. Seven nger equipment is extra. The running Is and guards are wide, and the rear is drop over the wheels. The running is and front floor boards are covered pressed aluminum.

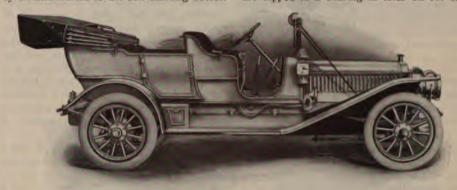

her new features are as follows: New n radiator with longer tubes, longer cap of hard rubber, and hard rubbering wheel rim; longer spark and throtevers on steering column, increased leverage, solid brake spiders, long or pedals at buyer's option, carburetor or on dash, improved design of auxilgasoline tank on dash, dual ignition with ge battery for starting, larger oil tank, e cups on springs, larger exhaust tube, r front universal joint with lubricant ner. The use of the self starter intro-

duced two years ago is continued and the starting crank is carried in the tool box.

In the brake lever segment is drilled a hole to receive a padlock. When the lever is drawn past this hole and the padlock is inserted the clutch is out and the brake is applied, so that the car is protected against theft. A feature of interest is that of mechanical inflation of the tires. This is done by an attachment to the self starting device.

angularity of the connecting rods and equalizing the side thrust against the cylinder walls. Long connecting rods and long pistons in connection with the offset crank shaft also aid in reducing side wear.

Each cylinder is submitted to a hydraulic test of 300 pounds per square inch and is ground to size, and after the engine is assembled the cylinders, pistons and bearings are lapped to a bearing in clear oil for six

THE 1910 WINTON SIX.

A tube supplied with the car is attached at one end to the self starter cock on the dash and at the other end to the tire to be inflated. When the valve on the dash is opened the compressed air flows at once from the pressure tank to the tire.

The motor is a six cylinder, four cycle, water cooled one, with 4½ inches bore and 5 inches stroke, and has low three point suspension. All moving parts except the flywheel are enclosed. The water jackets are open on each end and one side of the cylinders, making it possible to thoroughly remove scale or dirt that may accumulate inside by removing the covers of the different openings. The cylinders are offset from the centre of the crank shaft, thus reducing the

hours. The piston has three eccentric rings with step laps. These rings are ground on three sides and are pinned in place. The piston pin is hollow, 13% inches in diameter and 411 inches long, and is held in place by two set screws which are locked with a spring steel wire. The pin is slit at each end and is secured by tightening the retaining screws. The piston has an oil groove about 3/4 inch wide and 1-64 inch deep around it where the piston pin holes are, which catches the oil and aids it to get to the hollow piston pin. There are four small oil grooves below the piston pin on the piston for smoothly distributing the oil from the splash.

The connecting rod is a drop forging of I section. The top bearing is of phosphor bronze, 11/8 inches in diameter and 2 inches long, and slotted at the top to catch oil from the splash. The lower bearings are of white bronze, 134 inches in diameter and 2 inches long. The crank pin bearing cap, instead of being ported at right angles to the rod, is ported at about 45 degrees, making it easy to adjust without tearing down the whole motor. The valves have nickel steel heads 21/4 inches in diameter, which are electrically welded to cold rolled % inch stems and have 36 inch lift. The valves are actuated by roller plunger with provision for adjustment. The valve springs, plungers and valve chamber plugs are covered by readily detachable pressed steel plates. The cams are hardened and ground internally and externally, and are keyed to the nickel steel cam shaft, which is also ground to accurate size. The cam shaft has six liberal bearings, which are provided with pockets to catch the oil from the splash for lubri-

CARBURETOR SIDE OF WINTON SIX CYLINDER MOTOR,

CARBURETOR.

cation. The cam shaft gear and fan and pump shaft gear are housed in an oiltight compartment which forms an integral part of the crank case.

The crank shaft is a drop forging of special heat treated nickel steel with the cranks set at 120 degrees. It has four bearings. The front bearing is 314 inches long, the second 33% inches long, the third 33% inches long, the fourth and last 33% inches long, and all are 134 inches in diameter. These bearings are bushed with white bronze.

The crank case is of aluminum alloy with three 5x8 inch hand holes. Each connecting rod has its individual splash basin, which is curved and maintains a constant level of oil on a grade or on the level. The case is divided vertically into right and left halves to provide for the ready removal of the crank shaft, connecting rods and pistons, without disturbing the cylinders or motor accessories.

There are an oil drain at the bottom of the oil manifold for flushing the case and a bleeder pipe to relieve crank case compression.

Water circulation is secured by a gear driven centrifugal pump. The water is filtered before it passes through the pump in the filtering chamber at the bottom of the pump. It is impossible for the water to clog the radiator or to cease circulating even though the pump should become deranged, as in that event the water passes through the pump chamber and the circulating systems on the thermo-siphon principle. The new radiator consists of vertical copper tubes with pins. The tubes have been lengthened 1 inch. The radiator filler is lengthened an inch and has a notched hard rubber cap. The back of the radiator is housed, except for the circle in which the fan operates, thus causing a conducted draught over the radiating surfaces. The radiator fan is gear driven through a friction clutch.

A force feed lubrication system is used with a continuous sight feed on the dash. A plunger pump, operated by an eccentric on the rear end of the crank shaft, takes oil from the oil tank at the left side of the

motor and delivers it through leaders to the crank shaft main bearings and the front gears. A second plunger pump operated by the same eccentric draws the oil from the crank case and returns it to the oil tank, where it passes through a strainer before being used again. The flow of oil is proportional to the motor speed and the quantity is regulated by a bypass. The cylinders are oiled by splash. The crank shaft is drilled from each main bearing to one of the crank pin bearings, so that the surplus oil is carried from there by centrifugal force to the crank pin bearing.

The carburetor has a single nozzle and a double throttle. The throttles act in conjunction with fuel valves to gradually increase the fuel supply. There is no automatic air valve. The carburetor is located on the opposit side to the valves and connected to the inlet manifold through a Y shaped pipe passing over the top of the cylinders. The motor is throttled mechanically by a lever from the steering column or foot button at the driver's right foot. A primer is located on the dash.

The Bosch dual system of ignition with a single set of spark plugs is used, and the plugs are placed horizontally over the intake valves. Attached to cylinders I and 6 are outlets through which a small portion of each charge of burning gas passes to a pressure tank placed between the left frame rail and the driving shaft. Here the pressure is stored until required to start the motor, when a cock is opened, allowing the gas to flow through the distributor to one of the cylinders. The pressure forces this piston down; at the same time another piston passes the firing point and the motor starts. However, if for any reason the first cylinder should fail to fire, the distributor sends the gas to the next cylinder in order and forces the next piston past the firing point, and so on. The self starter has but one moving part, the distributor.

The gasoline is forced from the 23 gallon tank at the rear of the car by a small plunger air pump in the crank case, driven by the same eccentric that drives the oil pumps, under 2 pounds pressure to a patented auxiliary tank on the dash which allows the gasoline to flow by gravity to the carburetor. The main tank is provided with a reserve supply compartment holding 3 gallons and an air dome which prevents the gasoline backing into the air lines.

The multiple disc clutch consists of sixtyseven steel discs, of which thirty-three are keyed to the transmission shaft and thirtyfour to the driving spiders which are connected to the flywheel. The discs are 50 per cent. larger than heretofore, and run in an oil bath and are carried on annular ball bearings. The clutch is contained in the transmission case and is accessible through a hand hole. Four springs placed at equal distances around the clutch distribute the tension equally on the discs. The springs are easily removed or replaced. The clutch and hand brake lever are connected so that FRONT SPRING, SHOCK ARSORDER AND SECTION OF the application of the emergency brake re-

leases the clutch. A selective type sliding gear transmission operating in an H qualrant with four forward speeds and revent is used. Direct drive on third speed and high speed on fourth. Both shafts are carried on annular ball bearings. The several shifting yoke shafts are provided with locking devices to prevent two sets of gears becoming engaged at the same time. The propeller shaft between the transmission and rear axle is provided with two universal joints of the roller and trummion type and between the flywheel and the clutch there is a double universal, the ends of the shifts being squared and working in a hardened sleeve with a squared centre. The rear miversal of the propeller shaft forms part of the main drive pinion shaft, which is carried on Timken bearings, and to which the bevel drive pinion is keyed and held in place by a nut and lock nut.

The rear axle is full floating, there being no load on the driving axle, the weight of the car being carried on drawn steel talolar axle ends. The differential is of the spur gear type and is carried on Timber bearings. The torque is taken upon a solid round torque rod with a forward ball end. which is held in a socket at the rear cross member of the frame. The frame is of cold pressed nickel steel with the side rails inswept at the front to allow for short turning. The frame is 4 inches longer than in 1909. Side rails and drop members of one piece channel section are strengthened at their joints by heavy gussets. The motor, clutch and transmission are carried on "drop frames," there being no sub-frame

The front axle is of heavy cold pressed nickel steel of channel section with Tmken bearings on the pivot pins and the wheel spindles.

The steering gear is of the screw and nut type with ball thrust bearings, both above and below the screw. A 17 inch hard rubber steering wheel is used, wih the spark and throttle control levers above on a stationary quadrant. There are four brakes on the rear axle, two internal and two external, with extra wide brake bands. The inner shoe is of phosphor bronze and the

REAR SPRING AND SHOCK ABSORBER.

outer bands are lined with composition. Both sets of brakes operate through equalizers. The use of semi-elliptic springs at both front and rear permits of low suspension of the body. The front springs are 42½ inches long, 2 inches wide, with eight leaves, while the rear springs are 51½ inches long and 2¼ inches wide, and have ten leaves. Each car is equipped with Winton design shock absorbers, rubber bumpers and jump straps, and there are grease cups on all shackle bolts. There are no holes through the spring leaves.

One radius rod extends from each frame rail back of the car centre to the spring seats. These rods are pivoted at both ends and work together, holding the rear axle always at right angles to the frame.

The wheels are twelve spoke artillery with 4 inch tires in front and 4½ inch in the rear, on quick detachable rims.

The dash is mahogany, with steel shield, and carries the spark coil, auxiliary gasoline tank, carburetor primer, oil sight feed, self starter gauge, push button and shut-off.

The International Harvester Company's New Model.

In addition to their regular high wheeled type of automobile the Akron, Ohio, branch of the International Harvester Company will put on the market for 1910 a four cylinder, air cooled, shaft drive model fitted with either solid or pneumatic tires. In general construction this model is conventional, but it presents some interesting details.

For the present one model only will be manufactured, fitted with a runabout body, with or without rumble seat. The chasses of both these models are the same, except for the gear reduction.

The motor is of the four cycle, four cylinder, vertical, air cooled type with the cylinders cast separately, with integral heads and cooling flanges. The combustion chamber is dome shaped, with the inlet and exhaust valves set

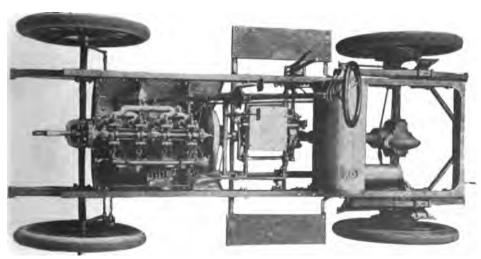

The connecting rod is an I section drop forging with a solid wrist pin end, bushed with phosphor-bronze. The wrist pin is secured in the cylinder by a set screw and cotter, thus eliminating the danger of the pin working out and scoring the cylinder walls. The crank pin end of the connecting rod is of the marine type, the cap being held in place by two studs each. Phosphor-bronze and babbitt are used for the bushing here.

The crank shaft is a drop forging, ground to size, and runs in five phosphorbronze bearings. The crank case is divided horizontally into two sections, the upper half supporting the main bearings and the lower half forming an oil reservoir. This lower section is divided into four sections for the oil, and into these oil wells the connecting rods dip, the motor depending entirely upon splash for its lubrication.

INTERNATIONAL HARVESTER FOUR CYLINDER MODEL-PNEUMATIC TIRED.

therein, opposite one another, at an angle of 30 degrees. The cylinders are bored and ground, with a bore and stroke of 3¾ inches. They are fitted with three rings each and have an oil groove turned in their lower end to aid in the even distribution of the lubricating oil over the cylinder walls.

PLAN VIEW OF INTERNATIONAL HARVESTER CHASSIS.

As shown in the side view of the motor, the valves are operated through rocker arms from the overhead cam shaft. This cam shaft runs in three roller bearings and is driven from the forward end by a silent chain from a sprocket on the forward end of the crank shaft. This chain runs in guides which prevent it from whipping, and thus reduces the wear to a minimum. The valves are adjusted through the flange connection between the cam shaft and the driving gear. As shown in the front view of the motor, the driving gear of the cam shaft is slotted with three slots, concentric with the gear centre, and is secured to the flange on the cam shaft by three studs which pass through these slots, which are about 11/2 inches long. Thus by loosening these bolts and shifting the flange the desired adjustment can be obtained. Finer individual adjustment to each valve is obtained by screws in the ends of the rocker arms.

The cooling arrangement is unusual for motors of this type, although the same principle has been extensively used on double opposed air cooled motors. Currents of air are forced directly onto the

exhaust valve pockets by two fans located on the exhaust side of the motor and driven through helical gears from a shaft parallel with the crank shaft. This shaft, which runs on ball bearings, is in turn driven by a friction pulley from the flywheel, the flywheel being beveled for this purpose, as shown. The driven pulley is held in engagement by a spring within itself. This system of cooling is said to be so efficient that the motor can be run on the block under full load for an indefinite period without overheating.

Lubrication is by splash within the crank case, the oil being individually supplied to each section of the crank case by a mechanical oiler which is driven by an eccentric from the magneto shaft, which in turn is driven by a silent chain from a sprocket on the rear end of the crank shaft.

Ignition is by batteries and magneto, the batteries being used for starting through the magneto wiring. The magneto is driven by the shaft referred to above. The carburetor is of the float feed type, with gravity feed from the tank located under the seat.

The power is transmitted through a leather faced cone clutch, through two universal joints to the change gear box located beneath the seat. The gears run on ball bearings and give two speeds forward and one reverse, being operated progressively. The final drive is by Cardan shaft to the semi-floating live rear axle. The Cardan shaft is fitted with one universal joint immediately to the rear of the change gear case, and beginning just beyond this is encased in a tube bolted to the differential casing, which acts as a torsion tube. The driving stresses are taken up by radius rods.

The rear axle is built up of semi-steel castings, the extension tubes being bolted to the differential casing. The brake spiders are cast integral with the extension tubes and the spring seats float on the axle, thus relieving the springs of driving and braking stresses. Taper roller bearings are fitted throughout.

The frame is straight, of armored wood construction, strongly braced. A subframe supports the motor and change gear box, and a steel under-pan protects the whole. The frame is supported on full elliptic springs front and rear, the rear springs, as already mentioned, being floated on the axle. These springs are 36 inches long by 1½ inches wide, of five leaves each, with forged lips to prevent them from shifting.

The front axle is an I section drop forging with integral spring seats and is fitted with taper roller bearings. Steering is through rack and pinion with the drag link behind the front axle. The steering wheel is 15 inches in diameter, of wood, over a bronze spider, and is mounted on a sharply raked column.

Braking is effected by one transmission brake of the contracting band type acting on a drum on the transmission shaft just behind the change gear box, and one set of internal expanding brakes acting on the rear wheels.

Control is by the usual spark and throttle levers located on the right hand side of the steering column, immediately below the wheel. One pedal controls the clutch and the other the transmission brake, and two hand levers at the side control the change speed gears and emergency brakes respectively.

With solid 2 inch tires the wheels are 38 inches in diameter, and with pneumatic tires the equipment is 34x3½ front and rear. The equipment consists of set of tools, five oil lamps, two gas lamps and generator. The weight complete is about 1,700 pounds.

Empire Removable Rim,

Following the trend of the times the Epire Tire Company, of Trenton, N. J., ha placed on the market a removable rim, illustrated by the two cuts herewith. So plicity of construction is one of the characteristics of this rim, which is claim

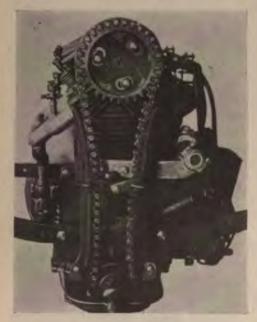

RIM IN POSITION.

to operate esaily and freely, and to be it possible to handle improperly. One of the cuts shows the rim bolted in place on the wheel. Each wheel has eight bolts, making a change only six of the bolts a loosened, the two bolts on both sides of the valve being left screwed up tightly at times. The nuts used have collars thread

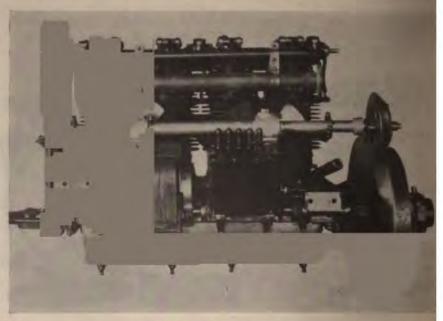

RIM LOOSENED.

on their inner sides, which makes it unnessary to remove them from the ends of bolt. It is stated that five turns of wrench loosen the nuts sufficiently to p mit of turning the lugs sideways so the rim may be removed. The other shows the nut loosened, the lug turned as and the rim partially removed.

FRONT VIEW.

Side View, Showing Fans. International Harvester Four Cylinder Motor.

Wohlfeld & Co., 538-540 North Third to Philadelphia, have placed on the set a tire trunk which is claimed to be ely waterproof. The cut herewith is the appearance of the trunk. The land back are made of three ply veand the sides are formed of heavy board. The trunk is leather bound, stitched, covered with black enameled and lined with felt throughout. It is with brass trimmings and heavy cowstraps. Among the claims made for runk are that it offers more available, that the contents are easier of ac-

WOHLFELD'S TIRE TRUNK.

than in the ordinary tire trunks, that is no hinge to break, and that the ving lid is always in place and always of the way.

#### Empire Checkered Tread.

e Empire Tire Company, of Trenton, , are exhibiting for the first time at Atlanta Show a new form of tire tread, h is to be known as their "checkered". It is of the same molded construcas used by the company during the

EMPIRE TIRE

year. The object of the checkered ruction is to give the tire non-skidding ties. A cut of the tire is shown here-

#### Foy Electric Rear Light and Number Holder.

is accessory, the general form of which own by the accompanying cut, is marby the Jordan Equipment Company, everly, Mass. It has a shell of speacquered brass, which breaks open at ottom, as shown in the cut, giving easy s for cleaning the interior silver plated tor. The lens is a standard railroad type (ruby red). The electric bulb a tungsten filament and is imported Germany. These bulbs are held in by spring cushion sockets at each no threaded connection being used,

FOY ELECTRIC REAR LIGHT AND NUMBER HOLDER.

and can be removed by simply pressing the spring at either end. A heavy ground glass runs the full length of the under part of the lamp, thus making a well diffused white light which completely illuminates the number and projects a beam of white light to the roadway, which is an added protection from rear collision. The lamp can be attached by two bolts, or it may be screwed to the back of the body or frame of the car. The switch should be located handy to the driver, so that the light can be turned on or off without leaving the seat. The number plate is slipped into the holder and is held in place by the heavy spiral springs.

Luxury Auxiliary Seats.

Graves & Congdon Company, Amesbury, Mass., manufacture a patented auxiliary seat for automobiles, motor boats, etc. The seat is attached by a dove-tailed socket secured to the side of the car, so that it can be put in place and removed instantly, without the use of tools. The seat rotates freely on its own bracket, so that its occupant can move about in a half circle with ease. The seats are hinged to the back, and when not in use can be folded against the back. These seats are made in two different styles, and each style in two sizes. The style A scat has a full upholstered back. extending from the seat to the height of the shoulders, while the style B seat is pro-

vided with a back cushion secured to upright metal rods. The two sizes are known as full and medium, respectively.

H. H. Franklin Manufacturing Company are erecting a 150x30 feet shed at their factory in Syracuse, intended for the storage of chasses awaiting the completion of their bodies. Improvements in Gabriel Horns.

The Gabriel Horn Manufacturing Company will continue to manufacture their Nos. 2, 3 and 4 horns, but in the 1910 models the two lower notes will be operated together, making a perfect chord, while the high note, which is two octaves higher than the bass chord, gives the effect of a soprano voice with a quartet. This change in combination is claimed to produce a singularly sweet, musical effect, and to give greater carrying power than any signal they have yet built. Sizes and weights of the different horns are as follows: No. 2 horn, 21/2 inch tube, 30 inches long, weight 4 pounds; No. 3 horn, 3 inch tube, 32 inches long, weight 51/2 pounds; No. 4 horn, 31/2

inch tube, 34 inches long, weight 61/2 pounds.

The 1910 valve is the same as the 1909 model, except that the lever is made from three-eighth inch material, and the screws which fasten the discs thereto are placed near the edge in such a manner that it practically forms one piece and greatly increases the strength of the lever. The valves are made in sizes from three-quarters to 3 inches for steel tubing, and from 1 inch to 2 inches for iron pipe. This valve can be used for muffler cut-out purposes by removing the disc in the main channel.

The Gabriel trumpet is another novelty which this company has recently placed on

the market, and which has already become popular. It consists of four single tubes, with a small valve at the end of each tube, which controls the tube individually. The trumpet is operated by a keyboard, consisting of four keys, each controlling one of the notes. All conbinations of trumpet and bugle calls can be played. The keyboard is also fitted with a small lever, which opens the four valves at the same time, thereby producing a perfect chord for signal purposes by simply pressing the pedal.

#### General Motors Absorb Cartercar Company.

The General Motors Company have absorbed the Cartercar Company, a \$350,000 corporation, of Pontiac, Mich. It is stated that the business was turned over to the new owners for a part cash and part stock consideration. The Cartercar Company was originally located in Detroit, but about a year ago was consolidated with the Pontiac Spring and Wagon Company, and was then removed to Pontiac. It manufactures a friction drive car.

# COMMENTS AND QUERIES OF READERS.

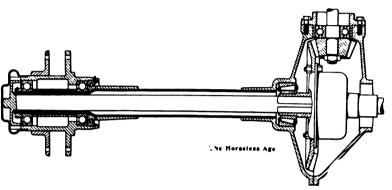

#### Queries.

Editor Horseless Age:

As an enthusiastic reader of your paper I will ask you to answer for me the following questions:

1. What is the difference between a se-

drive are live axles. A live axle usually consists of two essential parts, viz., the interior driving shafts and the exterior housing or casing. The floating axle is a live axle in which the tubular portions of the rear axle housing extend entirely

FULL FLOATING AXLE

lective and a progressive transmission?

- 2. What is a floating rear axle?
- 3. What is a semi-floating rear axle?
- 4. What is a live axle? A. E. P.

[In the progressive type of change gear you obtain the different forward speeds and also the reverse successively by a continuous forward or backward pivotal motion of the change gear lever. With a selective type of change gear, the gear lever has both a pivotal motion in a forward and backward direction, and a sliding (or pivotal) motion in a direction crosswise of the car. The progressive type of change gear generally has a single sliding set of gear pinions, while the selective type of gear usually has two independent sliding sets, and the object of the sideward motion of the gear lever in this latter type of gear is to drop one of the sliding sets and pick up the other.

To explain the different constructions of rear axles it is probably best to begin with a live axle. A live rear axle is one through which the power is transmitted to the driving wheels. The rear axles of all cars except those with side chain or side gear

through the rear wheel hubs, and the rear wheels turn on bearings on the outside of the tubes. All the weight on the rear wheels is then carried by the tubular axle housings, and the rear axle shafts are used only for transmitting the power to the rear at the inner ends of the axle shaft is the same as in a floating axle; that is, the bearings are mounted on the hubs of the differential, and not on the axle shaft directly. At the outer ends of the axle shafts of a semi-floating axle the arrangement of the bearings is, however, the same as in an ordinary live axle. The tubular axle housing in such an axle extends only to the inner ends of the rear wheel hubs. There is a bearing for the driving shaft just inside the outer ends of these housings, and the hubs of the rear wheels are keyed to the outer projecting portions of the axle shafts.—Ed.]

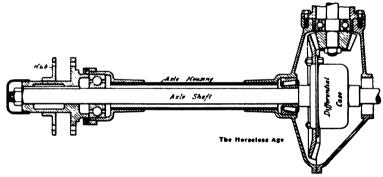

# Upward Thrust on Piston During Suction Stroke.

Editor Horseless Age:

Will you please tell me what a "flying" piston is and why its use is impracticable? Also what is the maximum upward thrust on a 5 inch piston during suction stroke of an engine running about 800 r. p. m.?

H. F. B.

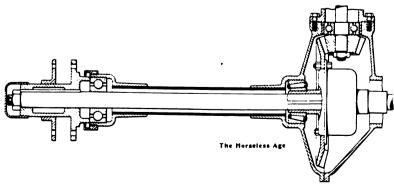

[We regret to be unable to inform you what is meant by a "flying" piston. The

ORDINARY LIVE ANLE.

wheels. The bearings on the inner ends of the shafts of a floating axle are also on the hubs of the differential gear and not on the axle directly. In a semi-floating axle the arrangement of the bearings term is probbaly used by some inventor to designate a special construction. If any reader can shed any light on the subject we shall be glad to hear from him.

The upward thrust on a 5 inch piston during the suction stroke depends (1) upon the suction or degree of vacuum in the cylinder, which in turn depends upon the cross section, length and general conformation of the inlet passages, and (2) upon the weight of the reciprocating masses. The first factor is beyond calculation. We may illustrate the calculation of the thrust on the piston, due to inertia, by assuming the weight of the reciprocating parts (piston, wrist pin and part of connecting rod) to be 10 pounds, and the connecting rod to be twice the length of the stroke, which latter we will assume to be 5 inches. The acceleration of the piston is a maximum when the crank passes through the top dead

SEMI-FLOATING AXLE.

centre (in a vertical engine). The acceleration at that moment is represented by the following formula:

$$a = \omega^2 r \left( 1 + \frac{r}{l} \right)$$

where w is the angular velocity in radians per second, r the length of the crank radius in feet, and I the length of the connecting rod in feet. Substituting in this equation the values which we have assumed.

$$a = \left(\frac{800 \times 6.28}{60}\right)^2 \times \frac{2^{\frac{1}{2}}}{12} - \left(1 + \frac{1}{4}\right)$$
= 1.847 feet per second per second.

The formula for inertia forces is

$$\mathbf{F} = \frac{a}{\mathbf{g}} \mathbf{W},$$

where a is the acceleration in feet per second per second, g the acceleration due to gravity (32.2 feet), and W the weight of the accelerated mass. Substituting in this formula we have

$$F = \frac{1,847}{32.2} \text{ ro} = 507 \text{ pounds.}$$
This is the maximum force due to ac-

celeration of the reciprocating parts. The force dut to the suction will hardly ever be greater than 3 pounds per square inch, considering the moderate piston speed. At the beginning of the stroke the suction force is nil, and it increases very gradually, owing to the fact that there is a considerable volume of spent gas in the cylinder at the beginning of the stroke. The inertia force, on the other hand, is a maximum at the beginning of the stroke and becomes zero before the stroke is half completed. In connection with it the suction force is practically negligible, and there is no doubt that the inertia force at the beginning of the stroke, as above calculated, constitutes the maximum upward thrust on the piston.-

#### Suitable Sizes of Electric Vehicle Lamps.

Editor Horseless Age:

On account of its greater convenience and cleanliness I am thinking of using dynamo and storage battery for lighting my lamps, including headlights. What candle power electric lamps should I use to replace the 34 foot burners on acetylene lamps, and what is the usual power of side oil lamps? What size storage battery would you recommend, and how long would it light all five lights with the dynamo running? S.

[A 3/4 foot acetylene burner gives 37 candle power, but it is advisable to get along with a somewhat less powerful lamp if you wish to use electricity. The headlights should be of 10 to 20 candle power, and for the side lights 2 to 4 candle power is sufficient, and the rear light need only be 2 candle power. These lamps consume about I watt per candle power, hence when all lamps are burning the electric energy consumption would be about 26 watts if the smaller sizes of lamps are used and 50 watts if the largest lamps are used. The output of the dynamo is very probably

greater than this, so with the dynamo running the lamps should burn indefinitely, no matter what size battery you use. A 6 volt 50 ampere hour battery should be ample, as it will be drawn upon only when the car is stationary or the engine running very slow. Without the dynamo running this battery, when fully charged, should run all five lamps (the largest size mentioned) for six hours.—ED.]

#### Rotary Motors.

Editor Horseless Age:

I notice a statement that the French rotary gasoline motor built for aeroplane use has been scrapped and replaced by a standard motor. A large amount of money was spent in experiments with this motor, and apparently the problem of gasoline supply to cylinders from the inner and not from the outer ends (against centrifugal force) was satisfactorily solved.

Specific oil consumption, 0.184 kg. (= 0.405 lb.) per horse power hour.

Features of Motor-

Number of cylinders, seven.

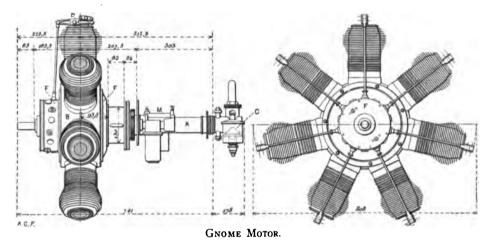

Cylinder bore, 110 mm. (= 4.4 inches).

Piston stroke, 120 mm. (= 4.8 inches).

Fuel supply, spraying carburetor. Ignition, high tension magneto.

Cooling, by displacement of air by the motor

The crank shaft of the Gnome motor is fixed and the seven radial cylinders turn around it. The shaft is hollow and comprises a crank pin, which is also fixed in space, which carries two ball bearings supporting a master connecting rod. This rod connects to one of the pistons. The other pistons connect to small connecting rods pivoted to the master connecting rod. The outer ends of the connecting rods are attached to hubs which are fixed to the piston and secured by the inlet valve boxes, which serve as check nuts. The seven cylinders are made of nickel steel and are "worked from

C, carburetor; F, valve gear housing; B, cylindrical portion of crank case; A, hollow shaft; M, magneto; C, exhaust tappet lever.

Could you inform those of your readers like myself interested in hitherto unsolved problems of rotary motors why this French rotary is a failure, and give some diagram of its construction?

[This motor, which was used by Henry Farman during the Rheims week and later, has probably been discarded by him, if you have heard such a report. It can hardly have been discarded by the manufacturers, as they exhibited it at the Paris Aeronautical Show only last month.

The motor was entered in the contest of light flying machine motors of the A. C. of France, and from the report on this contest we take the following description and test results:

RESULTS OF TEST OF GNOME MOTOR.

Average speed for 15 minutes, 1,177 rev. p. m. Average power for 15 minutes, 34.2 h. p. Total fuel consumption in kg. per hour, 12.26. Average oil consumption in kg. per hour, 6.29. Weight of motor and accessories, 82 kg. (= 180 lbs.).

Weight of fuel and supplies consumed per hour, 100.57 kg. (= 221 lbs.).

Specific weight, 2.94 kg. (= 6.47 lbs.) per horse power.

Specific weight of motor alone, 2.19 kg. (= 5.26 lbs.) per horse power.

Specific fuel consumption, 0.359 kg. (= 0.79 lb.) per horse power hour.

the solid." The exhaust valve is located in the centre of the cylinder head.

The crank chamber consists of a cylindrical box, with separate end plates, of which one constitutes a thrust plate and the other a cam gear casing. The cylindrical portion of the casing is provided with seven openings, into which the cylinder ends are forced under pressure, and held in place by steel segments and clamps parallel to the centre line of the crank case. The centrifugal force has the effect of squeezing the segments between the inner and outer walls of the joint. All parts of the crank chamber are also of nickel steel. The end thrust plate is provided with ball bearings, and these act in both directions, which permits of fixing to the plate a propeller which exerts either a push or a pull on the motor. The cam gear casing contains the forward ball bearing as well as the cam gears.

The inlet valves are of the automatic type, and are located in the piston heads. The gaseous mixture is first drawn into the crank chamber, as we shall see further on. The exhaust valves are balanced by means of a system of counterweights, in order that their operation may not be influenced by centrifugal force. Inside the cam gear housing are placed the half time gears and

Total

Distance

Day's

Mileson

the seven cams, which effect the opening of the exhaust valve by a pulling action. A double rocking lever, provided with balance weights designed to avoid unnecessary strain on the cams due to the action of centrifugal force on the valves, opens the exhaust valve. The exhaust vales are closed by a spring, and the balance weights are so calculated that in case one of the springs breaks the centrifugal force on the valve is still sufficient to close it, so the cylinder affected will still keep operating.

The carburetor is of the spraying type. It is provided with a supplementary air valve and with a float chamber. It is placed at the end of the hollow crank shaft. The suction in the crank chamber, due to the in and out motion of the pistons, draws the combustible mixture into this chamber, through the carburetor and the hollow crank shaft.

The high tension magneto is driven from the crank shaft in the ratio of 7 to 4. It furnishes current to a high tension distributor of hard rubber with seven contact segments. The spark plugs have been specially designed to be able to withstand the centrifugal force.

The cylinders are provided with circumferential cooling flanges. No fan is used, sufficient cooling effect being produced by the motion of the cylinders through the air. Oil leads passing through the hollow shaft of the motor supply oil to the connecting rods and bearings, and from there it passes through oil channels to the cylinder walls. The oil pump is placed symmetrically with respect to the magneto, and is of the two cylinder type with distributor.—ED.]

# Automobile Assessed Separately. Editor Horseless Age:

As a resident of a borough in the State of New Jersey I write to ask you if you would inform me whether it is according to the law for such a borough to render a separate tax bill based upon an assessment of an automobile? I was under the impression that the State alone could impose such a tax, while a borough might—as many do—impose such a tax by including same in the personal property assessment.

#### SUBSCRIBER.

[The borough can collect a tax on the automobile as personal property, and there is nothing in the laws of your State which prevents the tax collector from sending you several bills, each for a part of your personal property. You should inquire whether or not the tax is a personal property tax. If it is, you will probably have to pay it.—Ed.]

### Part of the Equipment Missing. Editor Horseless Age:

A new owner had just received his car from the factory and was carefully checking off the equipment received against the list in the catalogue. Only one thing enumerated in the catalogue was missing, so he wired the factory: "Cannot find wheel base; send it at once by express."

E. T. BIRDSALL.

# Records of Operation of a Coal Truck.

Editor HORSELESS AGE:

Date

As your publication is interested in the progress of the motor truck, I take this opportunity of forwarding you data on half a month's work of our 10 ton truck, about which the public knows very little.

The data speak for themselves, and it is evident that the large unit is the most economical wherever it can be put into practice. Burns Brothers have put in a special chute in their coal yard, with which they load the truck in a minute and a half. This greatly helps the output.

The car does not show any abnormal wear, and there have been no breakages or serious deterioration of parts

When a car is able to deliver 4,000,000 pounds of coal a month, or 50,000,000

Gas,

Callons

pounds a year, at half the cost of delivering with horses, the automobile has certainly come to stay.

HEWITT MOTOR COMPANY,
Edward R. Hewitt. President.

#### "Graphite or Talc?"

Editor Horseless Age:

In a communication to THE HORSELESS AGE of October 27 William Hinds mentions the use of flake graphite instead of talc to prevent inner tubes from adhering to the covers. I removed an inner tube yesterday which adhered so tightly to the cover that it required a great deal of care and time and a free use of gasoline to separate it without serious damage. I think every autoist has had similar experiences with tires that have been run several thousand miles before being punctured, even

### TRUCK OWNED BY BURNS BROTHERS. FOURTH MONTH OF OPERATION.

Tires in excellent condition; will certainly go eight months and probably more. No delays, no loads missed in four months. Car in excellent condition.

#### Base—Thirty-eighth street and North River. Loads—Average weight, 20,250 pounds.

#### Fiat World Speed Record Holder in Atlanta Events.

The Fiat Automobile Company, of this city, have brought to this country for competition in the speedway races at Atlanta this week the 175 horse power Fiat with which Nazzaro made the world's record of 121.64 miles an hour at Brooklands track, England, the fastest time ever recorded for a gasoline car on any course. This record was made on June 8, 1908, in the memorable match between Nazzaro and Newton, which Nazzaro won, and which was officially timed by the timing committee of the Brooklands Automobile Racing Club with an electric timing and recording device.

The record was a big improvement over the previous "2 mile a minute" made by Demogeot at Ormond, Fla., for the latter was over a straightaway course, while Nazzaro's performance was on a 2 mile track. The Fiat's time beat Demogeot's by a goodly margin, actually covering 2 miles 144 feet in one minute. In the straight stretches of the oval Nazzaro, of course, even exceeded this terrific speed, but was timed only for full laps.

This big car, which was recently purchased by E. W. C. Arnold, the New York motor enthusiast, is being driven at Atlanta by Lewis Strang. Since the car made its great record at Brooklands many efforts have been made to bring it to this country. While it is a specially built racer, there is absolutely nothing freakish in its design, and it is constructed along the general lines of the regular large Fiat models.

It possesses a huge motor, with four cylinders cast in pairs. The bore is 190 mm. (7.48 inches) and the stroke 160 mm. (6.29 inches). The single cam shaft is located on the off side of the engine within the crank chamber, and is driven by the exposed timing gears. The cam shaft carries a second and smaller very thin spur wheel to drive the low tension magneto. Inlet and exhaust valves are placed overhead. The inlet valves are operated by long tappet rods and rocker arms. The inlet valves are about 3½ inches in diameter. The exhaust valves are on the opposite side;

also operated by tappet rods and rocker arms, and there are eight valves, two to each cylinder, which are placed side by side and proportionately as large as the inlets. When the exhaust tappet rods are at their lowest points the respective arms clear the cross rod, which supports the inlet valve rockers by only little more than the thickness of thin cardboard, which reflects the endeavor of the designers to utilize the available space to the best advantage.

#### Results of Salina Endurance Contest.

In the recently held Salina, Kan., endurance contest the first prize in the dealers' class, \$50, was awarded to the Maxwell roadster No. 5, driven by S. C. Bragg, which was the only car in its class to finish with a perfect score. The silver cup offered in the class for private owners was awarded to F. S. Gilman, of New Cambria, driver of Franklin No. 11, which also was the only car to finish perfect in its class.

#### Imports for October.

At the port of New York there were imported during the month of October by dealers 53 new pleasure cars (including 14 Fiats, 11 Lancias, 6 Delaunay-Bellevilles, 5 Renaults, 5 Benz, etc.), 42 taxicabs (including 25 De Dions and 10 Fiats), and 1 truck; and by owners 102 old cars, of which 70 were of domestic manufacture and 29 new cars.

#### Strang's Fiat Did Not Break Steering Knuckle.

We are informed that the Fiat car, No. 1, driven by Lewis Strang, in the Vanderbilt Cup race, did not break its steering knuckle, as stated in our report, but that the sole cause of its withdrawal was the damage to its radiator caused by a flying stone. The radiator would no longer hold water, and it was necessary to withdraw the car after the first lap.

LEWIS STRANG AT WHEEL OF THE ONE HUNDRED AND SEVENTY-FIVE HORSE POWER FIAT RACER.

### THE FIELD OF COMMERCIAL APPLICATIONS.

#### Taxicab Service in Atlanta, Ga.

The Atlanta Taxicab Company was incorporated under the laws of Georgia in November, 1908, and began operations in Atlanta on March I, 1909. Its garage and offices are located together at 112 East Ellis street, Atlanta, in a two story brick and concrete building erected especially for its use. The building has 52 feet front by 137 feet depth, with a yard in the rear in which are the lubricating oil storage and the machine shop and pit in an annex to the garage.

The Sultan taxicab is operated by this company, made by the Sultan Motor Company, of Springfield, Mass. The cars used are 26-28 horse power, or 14 French rating.

Sixteen cars are now in operation. The manager of the company states that the company expects to keep on adding to the number of cars in operation until about twenty-five are on the streets, making the additions to its service as it finds the traffic offers demand. The company has estimated that Atlanta is a twenty-five taxicab city.

All of the company's business is done from four private stands located at the two depots of the city, at its principal hotel and its principal club. One of its stands is in front of Durand's restaurant in the Union Depot. Another is in front of Jacob's branch pharmacy facing the plaza of the Terminal Station. A third is alongside the Capital City Club, at Ellis and Peachtree streets. The fourth is across Luckie street from the main entranec of the Piedmont Hotel. These are held to cover strategic points of the city from the company's standpoint.

In this connection the company has insti-

tuted an innovation in its service-a private telephone system that connects directly with the starter's board at the garage from any one of the four private stands. At the Piedmont Hotel stand, across from the hotel, in the little office that the company rents, is one of the telephones, which any patron may ring and secure direct connection with the starter, if there be no cab on the stand at that moment. At the three other stations are call boxes of iron on iron posts at the curbing, very much in appearance like police call boxes or fire alarm boxes. These are open, too, to the service of the public. A prospective patron opens any one of the boxes and secures direct connection with the starter, if there is no cab on that particular stand; and the starter, consulting his board, sends the nearest cah to the stand.

By means, also, of this private telephone system the starter is enabled to keep check on the cabs themselves. A driver, leaving a station, reports his time and whether there is another cab on that station. If there be no cab there, and one is available on another station, the starter rings up the other station and orders one of the cabs to cover the bare station. The driver reports when he reaches the bare station, and his name goes up on the board for that point.

Every call over both the Atlanta and Bell telephone systems comes to the starter's telephone, in addition to those which come over the private system. If the call comes over the public telephone the starter sends a cab from the nearest station, making the necessary moves of the name slips on his board. One starter is in a position by this

method to keep all the stands covered and to render immediate service.

The Atlanta Taxicab Company uses pneumatic tires. Stepney spare wheels are used solely.

The rates are as follows: By distance, first half mile or fraction, 30 cents; each quarter mile thereafter, 10 cents; waiting. each six minutes, 10 cents; extra charges. for ordering a cab to a point 11/2 miles or more from the centre of the city, 20 cents; returning charge, when dismissed 1½ miles or more from the centre of the city, 20 cents. The same rates apply both night and day. They are for the exclusive use of the cab. One, two, three or four passengers will be carried on one charge. Not more than four passengers are allowed. If the cab is disabled the service up to the disablement must be paid for. A cab ordered and not used must be paid for up to the time the driver is dismissed, including charge of 20 cents for sending it. Coupon books at a discount of 5 per cent, are on sale at the main office and the stands. Large baggage cannot be carried.

The company gives no special private service at monthly rates. Service is given at flat rates of \$4 for the first hour and \$3 for each hour after that.

Popp taximeters are used, made by the Franco-American Taximeter Company. They are driven from the left rear wheels of the cabs.

All of the necessary repairs on the cars are made in the shops of the company at its garage. There is no maintenance contract with tire manufacturers. A tire record is kept, however—a daily record of the mile-

#### TAXICAB OPERATING COMPANY No. 948. Gasoline Supplied......Gals. Driver No..... Gasoline, In..... Gals. Oil Supplied......Pts. Date...... Gasoline Used......Gals. Taxicab No..... age made on each casing. This record is carried forward until the casing has to be taken off for repair or replacement. The company is supposed to get 3,500 miles on each casing. If the casing fails before that a replacement is allowed to the company. But the casings have been giving nearly 4,000 miles of service.

The daily mileage of each cab is reported as about 40 miles. The company's operators are paid 20 per cent. of their earnings. Lubricating oil is furnished free to the operators. Gasoline also is furnished free of charge until the driver makes \$12 on the week's work, when it is charged to him at cost price in the following proportions: \$12 earned, but less than \$14, one-third; \$14 earned, but less than \$16, two-thirds; \$16 or more earned, the whole cost.

The operating company leases the cabs owned by the taxicab company, paying the taxicab company 75 per cent. of the net profits.

The busiest hours of service have been found thus far to be as follows: In summer

on week days, between 10 o'clock and noon, between 2 o'clock and 5 p. m., and between 7:30 o'clock and 11 p. m. In winter on week days, between 1 o'clock and 4:30 p. m., between 6:45 o'clock and 9 p. m., and between 10:30 and 2 a. m. On Sundays the busy hours stretch from 2 o'clock in the afternoon practically through to midnight.

There are no specific ordinances regulating the taxicab service in Atlanta. The taxicabs are operated under ordinary hack rules.

In addition to the private telephone and call box system, the Atlanta Taxicab Company has another feature that is original—its dormitory for the drivers on late runs. This dormitory, or sleeping quarters, is provided on the second floor of the garage and office building. It is equipped with beds, closets and bathrooms.

Only two printed forms are in use in the company's offices. When the company began operations last March it had secured a number of printed forms from other companies. The management picked out what it considered the best features of the forms it needed, and embodied those features into tentative forms that are still tentative. Only two forms have become definite enough to

be printed. The company has put in a card index system. It pays its drivers weekly. The company is running separate record systems on casings, gasoline and spare parts. Gasoline used is charged to the drivers each day, in the quantity used on the preceding day.

#### Motor Mail Service in Columbus, Ohio.

The post office at Columbus has been authorized to establish an automobile collection service, beginning January 1. Postmaster H. W. Krumm has been in communication with the Post Office Department at Washington for several months, with the result that his request was granted. It is expected that with three automobiles and six collectors, a night and a day shift, the collection service can be much improved over the present system, with eleven wagons and eleven collectors. The cars will be rented from local garages, and chauffeurs will be supplied by the parties renting the cars. They will be of the same style as the horse drawn delivery wagon, with screened sides and rear entrance.

#### Motor Bread Delivery.

Charles A. Grosch, a baker, of Piqua, Ohio, is probably one of the first bakers in the country to introduce the motor delivery. He uses a 16 horse power 1906 model Franklin car. A set of Swiss bells carried under the top extension over the driver's seat announces the arrival of the bread wagon. The rear of the car platform is enclosed, providing a series of receptacles capable of holding 550 loaves of bread, and above the hood is a box 14 inches deep for storing additional bread. Mr. Grosch states that he saves two hours each day by the use of the motor car.

#### Commercial Notes.

The Baldwin Locomotive Works, Philadelphia, have put into commission a 3 ton motor truck for service between their works in Philadelphia and their foundries and branch works some 13 miles away.

An automobile line from Earlington to Pioneer place, Seattle, is to be established at once by C. D. Hillman, a real estate dealer of Seattle. Six automobiles of the sightseeing type will run hourly between the two points.

The Union Trust Company, of Indianapolis, has purchased a touring car, to be used in showing real estate to prospective purchasers. A number of real estate dealers of the city are using automobiles with excellent and economical results.

The Warfield-Pratt-Howell Company, of Cedar Rapids, Ia., have placed in service a motor delivery wagon, equipped with a 25 horse power engine and designed for a carrying capacity of 3 tons, which was built by a local firm, Beck & Son. It is the first of its kind and was placed in service tentatively.

William Holden, an enterprising rural mail carrier at Sparta, Wis., is now making his route in an automobile. In this way he saves 50 per cent. of time.

The Acme White Lead and Color Works, of Detroit, Mich., who put a power wagon in service a year ago, have added another machine of the same make, the Grabowsky.

We are informed that the Brazilian Government has just placed an order for fifty Saurer trucks. These trucks will be shipped direct from Switzerland from the Saurer factory to Brazil.

A motor sprinkling truck may be purchased by the city of Two Rivers, Wis. The city now maintains five horse drawn carts and hires five drivers. While the initial cost of a truck would be comparatively heavy, all of the carts could be discarded, and the saving, it is said, would pay for the truck in one season.

#### Windsor White a Licensed Association Representative.

The Association of Licensed Automobile Manufacturers held its annual meeting at 7 East Forty-second street, New York, on Thursday of last week, at which the following officers were elected for the ensuing year: Charles Clifton, president; S. T. Davis, Jr., vice president; L. H. Kittredge, secretary; Col. George Pope, treasurer. The executive committee will consist of Charles Clifton, S. T. Davis, Jr., Thomas Henderson, Hugh Chalmers and Herbert Lloyd. The Waltham Manufacturing Company, a former member of the licensed association, which went out of business about a year ago, was represented by Windsor T. White, of the White Company, Cleveland, Ohio, from which it is inferred that the latter company has acquired or is about to acquire the license of the Waltham Company. Among the new members of the association, the Dayton Motor Car Company was represented at the meeting by C. G. Stoddard, the Hudson Motor Car Company by R. B. Jackson, the Jackson Motor Car Company by G. A. Matthews, the Maxwell-Briscoe Motor Company by Benjamin Briscoe, the Olds Motor Works by C. R. Hathaway, the Reo Motor Car Company by R. E. Olds and the Toledo Motor Company by J. N. Willys.

#### R. M. Owen Issues a Challenge.

R. M. Owen, who drove one of the new four cylinder Reo roadsters in the New York-Atlanta tour and finished with a perfect score, upon his arrival in Atlanta issued a challenge to the effect that all of the competing cars immediately after being checked out at Atlanta should be submitted to a technical committee, composed of Referee Winthrop E. Scarritt and the officials who checked and examined the cars at the start, for a critical and exhaustive examination under rules determined by the committee. Mr. Owen offered to pay all expenses of the examination. The findings of the committee were to be final.

### AUTOMOBILE LAW AND LEGAL EVENTS.

#### Recent Decisions.

DUTY OF STREET CAR PASSENGERS WHEN ALIGHTING.

A street car passenger in alighting was held required to look for approaching vehicles when she stepped from the car to the street, and the failure to look rendered her guilty of contributory negligence.—Kauffman vs. Nelson, Pa. 73 Atl., 1105.

In this case she did not look until after she had taken several steps from the car. When she saw the automobile she hesitated, and the auto turned to the curb to avoid her and she stepped in front of it.

FAILURE TO CHECK SPEED MAKES DRIVER LIABLE.

Where a pedestrian and the driver of an automobile became confused and zigzagged across the street, and finally the pedestrian was hurt, it was held that the failure of the defendant to check the speed of his machine, or to stop it if necessary, rendered him liable for damages.—Weil vs. Kreutzer. Ky. 121 S. W., 471.

#### REPLEVIN FOR AN AUTOMOBILE.

In an action of replevin for an automobile where the defendant alleged that the contract for the sale was in writing between the plaintiff and another partly jointly and the defendant, it was held that such other person was a necessary party to the action—Swenson vs. Wells, Wis. 122 N. W., 724.

# Jeffery Is Granted Big Damages. Against Railway Company.

A verdict of \$133,000 damages was granted Thomas B. Jeffery & Co., of Kenosha, Wis., against the Chicago & Milwaukee Electric Railway Company at the conclusion of the second trial of the suit resulting from the division of the Jeffery tract by the electric's right-of-way, making contemplated extensions of the Rambler works impracticable. The Jeffery company sued for \$2,000,000 damages and in the first trial was granted \$135,000. The Supreme Court called the amount excessive and ordered a new trial.

#### Chicago Police Innovations.

The first experiment in patroling the streets in certain parts of the city of Chicago by a motorcycle squad began last week. At first the squad will consist of only three policemen, but if the innovation proves a success, Chief of Police Steward will increase their number. The present plan is to experiment with them in the messenger service, and instead of the police mail being brought to headquarters by policemen by way of the street cars the motorcycle squad will deliver it. Chief of Police Steward of Chicago is planning to leave cards with the owners of automobiles which stand at the curbs in downtown streets rotifying them that the city ordinance limits the time that a vehicle may linger in one spot to one hour. The cars will be distributed through the agency of the mounted police.

#### Rush for Ohio Licenses.

A check for \$100 from the Winton Automobile Company, of Cleveland, is the largest fee ever received by the Ohio automobile department. The fee was for licenses for the factory for the year 1910. The company desires to retain the same numbers, and the request was granted. There is a rush for owners to get the same numbers they had during 1910, and in many cases State Registrar of Automobiles Fred H. Caley is complying with the request, especially when a good reason is given. The registrar anticipates quite a rush during December and January, and the force of clerks will be more than doubled.

# Supplementary Spiral Spring Patent Interference Decided.

We are informed that the United States Patent Office on October 30, in the interference case entitled Graham vs. Furmidge, involving an application for patent filed by John Hector Graham on December 19, 1907, and the Furmidge patent, No. 807,612, assigned to the St. Louis Supplemental Spiral Spring Company, Inc., rendered a decision in favor of the latter. The St. Louis Supplementary Spiral Spring Company have filed suit in the United States Circuit Court at New York city against John Hector Graham and the Graham Company, doing business under the name Supplementary Spiral Spring Company, New York city, alleging infringement of their patents Nos. 807,612 and 901,578.

# Petitions for Return of Deposit Money.

W. W. Alexander, a New Mexico business man, has filed a petition with Judge H. C. Briggs, referee in bankruptcy for J. V. Lindsley & Co., of Dowagiac, Mich., for the return of the sum of \$1,000 which he claims to have deposited with the firm in connection with the purchase of two cars. Mr. Alexander claims that this sum was a trust fund, and should be returned in full, while counsel for the Lindsley Estate contends that Alexander made the payment in consideration of being taken into business partnership, receiving the exclusive agency for the Lindsley cars in the Southwest.

#### Warning Motorists of Speed Traps Illegal in England.

For many years the Automobile Association of England has been trying to break up the practice of the English police to apprehend speeding motorists by the operation of so called speed traps. As soon as

such a trap was established the association would place cycle scouts on the road to warn all approaching motorists. When accused in court of interfering with the police the officials of the association made the plea that what they were really endeavoring to do was to prevent motorists from breaking the laws, and in the lowest court their action was held to be not contrary to the law, but this ruling has now been reversed by the Court of Appeals.

#### Headlight Patent Sustained.

The Badger Brass Manufacturing Company, of Kenosha, Wis., has recently obtained a final decree, sustaining Letters Patent No. 841,799, dated January 22, 1907. granted to George Maris and La Société Besnard, Maris & Antoine, of Paris, France, for improvements in lamps and headlights. The suit was brought against Herman Saxon, at New York city, in the Southern District of New York. The usual perpetual injunction was granted against Herman Saxon and his agents.

#### Legal Notes.

Motorists of Vermont take certain pride in the fact that the State authorities received only six complaints during the past year regarding non-compliance with the automobile regulations.

The Chicago City Council has passed an ordinance requiring front and tail lights on all horse drawn vehicles, and the Chicago A. C. is taking steps to assure a universal enforcement of the measure.

. A new ordinance which limits the time that cars may be left standing at the curb in the downtown district to one hour went into effect in Chicago on November 2. The physicians and some other automobile users of that district strongly protested against the measure.

The Chicago City Council on November 1 passed an ordinance providing for the examination and licensing of all drivers of taxicabs and other public motor vehicles, and creating a board of registry to conduct the work. It has not yet been announced when the measure will go into effect.

An automobile concern, known as the Only Car Company, recently incorporated with a capital stock of \$300,000, has purchased the E. O. Lawrence property at Echo, L. I., and will immediately start the erection of factory buildings, the largest of which will be of concrete with a floor space of 16,000 square feet. The output of the company will include two, three, four and five passenger cars, taxicabs and light delivery wagons. Work on sample cars is now being carried on in temporary quarters. M. Francois Richard, M. E., will have charge of the works.

### CULLED FROM OUR FOREIGN EXCHANGES.

#### Overhauling a Motor.

When it becomes necessary to overhaul a motor the latter will usually give notice of the fact itself by giving out a very characteristic metallic sound, well known to every experienced driver under the name "knocking." The knocking is especially pronounced if the ignition is advanced slightly too much. This metallic sound is the result of shocks between the connecting rod and the piston pin on the one hand, and the connecting rod and the crank pin on the other, due to play in the bushings of the rod. As soon as this knocking becomes at all pronounced it is advisable to discontinue driving the car. The writer has seen connecting rod heads worn to such an extent as to split apart. This entailed the immediate bending of the crank shaft, and the connecting rod being no longer maintained in place broke at one stroke through the bottom of the crank case.

The first precaution to take in case a motor knocks is to demount the cylinders, after having first removed the inlet, exhaust and water pipes. This demounting process in general does not involve any difficulties. However, in some of the older types of motors the cylinder heads are separate, and these separate heads must not be taken off, as it is very difficult to make a good joint again. On the contrary, the cylinder and head should be removed together, as though they were made in one niece.

After this has been done one may easily ascertain by means of the hands if there is any play at either end of the connecting rod; if there is the crank shaft, the connecting rods and the piston pins must be

Fig. 1.

taken apart. In certain motors this latter disassembling process is quite difficult. These are the motors in which the crank shaft is introduced from the ends, the bearings being supported by end plates bolted to the casing. It is often a very difficult job in the case of such motors to remove the connecting rod caps inside the crank case, which must be done before the crank shaft can be withdrawn.

At the same time as the crank shaft the cam shaft and its gearing must be taken

out. Before disassembling the cam gearing it is necessary to mark the gears by means of prick punch marks in order to avoid laborious trials in putting the gearing together again. After the motor has thus been dissassembled, and all pieces have been duly cleaned by means of gasoline, the separate parts are taken in hand succes-

#### CRANK SHAFT.

The main journals and the crank pin journals must be carefully examined. As

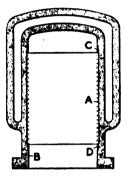

FIG. 2.

the crank shaft is the most expensive part of the motor it must be saved as much as possible. In most cases all of these journals will be found to have worn more or less oval, but as in general the crank shaft is not hardened, it is easy to true them up in the lathe. For truing up the main journal the crank shaft is placed in the lathe between centres, but for truing up the crank pin journal the crank shaft must be placed in special brackets, which bring the crank pins in line with the lathe centres.

If there are no suitable brackets available a lead lapping fixture is made use of (Fig. 1). This consists of two strips of wood, A and B, into which are sunk two half bushings of lead, C and B. The crank shaft being centred at F in the lathe, the workman presses the lead bushings, which have previously been covered with a paste of emery and oil, tightly against the pin. The lathe is then started up by the workman, who holds the "lapper" in his hand, the latter working exactly as a connecting rod. In this manner a good journal is obtained in short time.

No attempt should be made, however, to remove much material from the crank shaft, as, notwithstanding the fact that the sections are very liberally proportioned, there is danger of breaking the shaft, or, at least, of bending it. A reduction in diameter of one sixty-fourth inch is already considered quite appreciable.

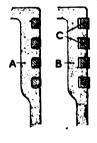

It is relatively rare that a crank shaft is found to be bent. This may occur if the flywheel of the motor strikes some obstacle in the road. A bent crank shaft is nearly always discarded, and only the factory which produced it can tell whether it can be righted again.

CYLINDERS, PISTONS AND PISTON RINGS.

The cylinders in the majority of cases are slightly ovalized. They may be made round again by reboring them, provided only very little stock needs to be removed, for if considerable material must be removed it is necessary to make new pistons of a larger size, which would be more expensive than to make new cylinders. If the compression rings are worn, they must be replaced, and care must be taken to nicely fit and grind the rings into the cylinders.

In this connection it should be remarked that a worn cylinder always has more or less the section shown in Fig. 2. The portion A, of a slightly increased diameter, is that where the piston moves up and down. The compression rings must, therefore, be forced through the section B and then expand in A. It is this latter diameter to which they should be adjusted. It is, moreover, a good plan to take out a light cut at C and D in order to remove the lower and upper shoulders of the "counterbore" A. If this is not done, after the slack on the connecting rod heads has been taken up the piston may hammer against the offset or shoulder and cause a mysterious noise. Where this precaution is neglected the motor, after being overhauled, often knocks as much or more as before, and much time may be lost in looking for the cause of this knocking.

With regard to the pistons there is little to be said, except that frequently the compression rings have too much play in their grooves, which take on a section similar to that shown at A, Fig. 3. The piston should

3712 Fig. 3.

then be put into the lathe and the grooves turned out to the normal section B, and special compression rings C must be made to fit these grooves without play.

If the cylinders are fitted with hand hole plates or cover plates for inspecting the interior of the water jackets these covers should always be taken off and the jacket space cleaned of the deposits of lime, as the cylinder walls will be nearly always found heavily incrusted. The valves are then ground into their seats,

after the latter have first been trued up with a valve seat cutter, if that is necessary. The cylinders are then in working condition again.

#### BEARINGS AND BUSHINGS.

The bearings (we are not referring here to ball bearings, which are as yet very little used in automobile motors) are of two different kinds, according to whether the bushings are entirely of bronze, or whether they are of babbitt. If babbitt bearings are used the babbitt is melted up and new bushings are cast, which requires a somewhat special equipment. In the case of bronze bushings, on the other hand, if the bushings are badly worn there is no other course open than to replace them entirely. If they show only slight wear it may be sufficient to repolish them by means of a scraping tool. If they are slightly more worn they may be counterbored and lined with babbitt. In every case the bushings and journals should be fitted by means of a scraping tool and red lead on the shaft until the bearing is perfect. This attention must be given to the main bearings of the crank shaft, the crank pin bearings and the cam shaft bearings. After the bushings have thus been thoroughly adjusted one must not forget to place oil holes in the proper positions nor to cut oil grooves in the bushings

The connecting rods and the cam shaft generally wear but very slightly, and all that is necessary to do is to examine them as to their straightness, as well as with respect to the keying of the cams, if the latter are not made in a single piece with the shaft.

#### ASSEMBLING.

This is the most delicate part of the entire process. The operation is the easiest in the case of a four cylinder motor having only three crank shaft bearings, especially if the bearing caps are independent of the crank casing. In that case the lower half of the crank case serves only as a dust guard and an oil well, and it is put in place only after all the bearings have been completely adjusted, which can be done in full view of the operator. Every part can then be thoroughly examined from underneath. Special care should be taken to see that everything turns nicely, that the connecting rods have plenty of play and do not cram any of the pistons in the cylinders. That the connecting rod heads are properly fitted on the crank pins is shown by the fact that they turn on the pins with some slight friction without oil. In the case of other motors the process of reassembling is sometimes quite difficult. The operator must not be in haste, and the process must be recommenced, if necessary, a number of times until perfect results are obtained.

After everything has been put back in place the cam gearing is taken in hand, which is put in place alone if the gears have been properly marked: then the lift of the valves is adjusted, either by filing off the valve stems or by adjusting the ad-

justable push rod heads, if these are provided.

The flywheel is then put back in place and the motor is connected to the shop line shafting by means of a belt running over the flywheel, after having first flooded the crank case and cylinders with oil. The pistons are thus allowed to run themselves in for a couple of hours. The motor is then cleaned, and is ready to be placed on the testing stand, if one is available; if not, it is put back into the car, which, after all, is an excellent testing stand as well. It will be seen from this that the overhauling of a motor is a tedious and delicate operation, and it is therefore not advisable to confide it to inexperienced hands. -Pierre Maillard in Omnia.

# Imports and Exports for September.

September seems to have been an off month for automobile imports, only 150 cars valued at \$231,811 and parts valued at \$80.-400 having been imported, as compared with 219 cars valued at \$352,295 and parts valued at \$103,038 during the same month last year. The returns for the two months show clearly how Italy is gaining on France in respect to automobile exports to the United States. In the following enumeration of the cars imported from the different countries during September last the figures in parentheses represent the number of cars imported from the same countries during the same month the previous year: France, 74 (156); Italy, 44 (27); United Kingdom, 14 (33); Germany, 7 (2); other countries, 11 (1). During the nine months ending with September last there were imported 1,208 cars valued at \$2,218,414 and parts valued at \$656,371, as compared with 956 cars valued at \$1,803,-889 and parts valued at \$451,469 during the same period the previous year. The figures for the different countries for these two periods, respectively, show that the imports from France have remained practically stationary, while the imports from Italy have increased about 80 per cent., and the imports from Germany by more than 400 per

September was another banner month for exports, there being exported 286 cars valued at \$373,754 and parts valued at \$01,658, a total of \$465,412, as compared with 128 cars valued at \$235,607 and parts valued at \$42.310. a total of \$277.917 during the same month last year. During the nine months ending with September last there were exported 2,426 cars valued at \$5,481,707 and parts valued at \$618,150, a total of \$6,099,-857, as compared with 1.812 cars valued at \$3.805,569 and parts valued at \$477,159, a total of \$4,282,728 during the same period the previous year. The heaviest increase is shown by the exports to British North America, which practically doubled and attained to near the \$2,000,000 figure for the first nine months of this year. The exports to Mexico also increased largely.

# Wisconsin Engine Company Takes Up the Owen Thomas Car.

The Owen Thomas Motor Car Company, of Janesville, Wis., is to be moved to Corliss, Wis. George Tener, of Pittsburg, one of the principal owners of the Wisconsin Engine Company at Corliss, and his associates have purchased the stock of the Janesville men who are backing Owen Thomas in the manufacture of the "O.-T. Six," and will reorganize the concern, increasing the capital to \$500,000. The Corliss works could easily be arranged to take care of automobile manufacture as it stands, but additions will be erected and the 1910 production will be rushed.

#### Milwaukee Show Dates Set.

The second annual Milwaukee automobile show will be held in the new \$500,000 Auditorium at Milwaukee, Wis., from February 22 to 27. The Milwaukee Automobile Club has started on preliminary work. The new building covers one square block, with a main hall covering more than half a block, the remainder being divided into smaller halls. The building is admirably suited for an automobile show, having a great oval arena, with a large stage at one end. The show committee appointed by President Drake is Dr. Louis Fuldner, chairman: Lee A. Dearholt, O. F. Fischedick and A. C. Brenckle.

#### Start of Los Angeles-Phœnix Race.

The start for the Los Angeles, Cal-Phœnix, Ariz., race took place at the former city on Saturday last, the following cars being dispatched at fifteen minutes intervals, beginning at 10 o'clock a. m.; Isotta-Fraschini, Max Persman: Elmore, George Dake; Pennsylvania, W. L. Vail; Dorris, W. R. Harrison; Franklin, Guy Irwin; Studebaker, Bert Latham; Ford, C. L. Harris: Columbia, H. Stone; Buick, J. K. Nikrent; Apperson, Harris Hanshue. The distance is 480 miles, and includes a long stretch of sandy desert, which makes it necessary for the cars to carry along all of their supplies and food for the drivers.

# Hatcher Auto-Parts Company Taken Over by Liggett Spring and Axle Company.

The factory plant and stock of the Hatcher Auto-Parts Company, Cleveland, Ohio, have been purchased by the Liggett Spring and Axle Company, of Pittsburg. The specialties manufactured by the Hatcher Auto-Parts Company will now be manufactured by the Liggett Company. In addition, the latter company are turning out at this time from their plant at Monongahela, Pa., all types of high grade automobile springs. They are now turning out roller bearings of an improved type, and also front and rear axles for several sizes of cars. William A. Cluff, who for the past five years has been manager of the Hatcher Auto-Parts Company, remains in charge of the Cleveland factory.

### GARAGE AND SALESROOM.

The Illinois Garage Association.

The Illinois Garage Association was organized in May, 1909, with the following officers: Lathrop H. Collins, Terminal Garage, president; A. H. Blair, Drexel Auto Company, vice president; H. E. Halbert, Garfield Park Auto Garage, vice president; John W. Morsbach, Lake View Auto Company, secretary; James F. Mraz, Edgewater Garage, treasurer; R. F. Patterson, manager.

The association undertook to remedy many of the difficulties of the garage owner in conducting his business under the bad conditions existing in the city of Chicago in this line of industry. The first step in this direction was to have the various garage owners get acquainted, so that they were in a position to communicate with each other, not only on business but socially. This led to a comparison of individual experiences in doing business with that very undesirable class of patrons who, after running up a large bill in one garage, leave it without paying the bill and go to another garage where they repeat the performance, so that in some cases it was found that a certain car owner had run up a bill of considerable size in each of five different garages on the north side of the city. The association now takes care of this class of patrons by classing them as "delinquents." A list of these is kept up to date, and furnished to each garage member who consults it before opening accounts with new customers.

The matter of collections is also looked after by the secretary of the association, and this furnishes another line on those who neglect to pay their bills without justification or excuse.

A most important step in the protection of the organization was the promulgation of a uniform set of garage rules. These rules are posted in a conspicuous place in every association member's garage. The patrons are informed that they may procure a copy on application at the office. The adoption of the rules was followed by mailing a copy of same to each garage patron at the time the monthly statements were sent out. These garage rules protect the garage owner from and against liability in all of the many situations and contingencies in connection with fires, accidents, explosions, loss of personal effects from cars, careless chauffeurs, the quantity and kind of service the garage is to render, and when monthly bills must be paid. The rules also cover the question of liability for damage to cars while in the possession of chauffeurs, the insurance feature, defining dead storage, notifying delinquent owners that the car will be held unless charges are paid, and requiring notice from the customer of his intention to terminate his storage contract

so that the space may be rented to new customers.

The matter of the purchase of supplies through the association for its various members, in order to get the benefit of the quantity price, is also under consideration, and plans are being perfected for the handling of this matter satisfactorily. This presents a good opportunity for effecting a large saving in this branch of garage expense.

The question of prices has not been interfered with except as between competing garages in some particular neighborhood, where the association uses its good offices and best efforts as arbitrator to promote peace and harmony, to the end that those particular local garages may get together and settle their differences among themselves without interference or coercion of any sort from the association. This has been found to work far better than would any attempt of the association to control the situation.

Another feature about to be inaugurated is the distribution of a garage credential certificate among the patrons whose record for prompt payment of bills is good. The association issues these credentials which are turned over to the garage members. The garage then presents the same to its patrons with instructions how they are to be used. The object of these credentials is to introduce, identify and procure credit for the holder in the event of an emergency breakdown when on the road anywhere in the vicinity of an association member, so that upon presentation of the certificate the holder may secure prompt and courteous treatment as well as such credit as he may reasonably require for service or supplies sufficient to enable him to proceed on his

The membership of the association now embraces about 60 per cent. of all the garages in Chicago. A banquet has been arranged for to be given at one of the prominent hotels some time during the current month, at which a large increase in membership is expected.

The situation among the garage owners has been vastly improved through the efforts of the association, and the members are most enthusiastic over what has been accomplished and what the future will bring forth. The association maintains an office in the Corn Exchange Bank Building.

#### Garage Notes.

BRIDGEPORT, CONN.—Plans for a garage for the police and charities departments have been approved by the mayor.

GOUVERNEUR, N. Y.—The new garage for A. S. Whitney, on John street, will be thrown open to the public this month. The building is one of the most modern con-

structed, and over the garage proper is a large hall, where social events may be held.

WATERTOWN, MASS.—Charles Brigham is erecting a one story garage on Garfield street, to cost \$2,500.

ATCHISON, KAN.—E. B. Westfall, of the Kirkpatrick-Westfall Automobile Company, is looking for a site for a garage in this city.

DE KALB, ILL.—The Dean Auto Inn Garage have had plans drawn for the construction of a garage in the heart of the Glidden House.

St. Louis, Mo.—Seneca N. Taylor has been granted permission to erect a two story brick garage on Delmar avenue, near Clarendon avenue.

PHILADELPHIA, PA.—Plans are being prepared by Geo. H. Backmire for the erection of a two story, 66x100 foot brick garage at Eleventh street and Erie avenue, at an estimated cost of \$12,000.

COLUMBUS, OHIO.—The Speedwell Company, of Dayton, will soon open an agency in Columbus with Kimmel Brothers, in a new building at Spring and Fourth streets. Kimmel Brothers are already here with a demonstrator.

COLUMBUS, OHIO.—Frank Corbett, who represents the Maxwell in twenty-three counties in central Ohio, will soon move into his new salesrooms at 58 to 62 East Spring street. The building is now being remodeled for the agency.

SHELBYVILLE, IND.—The Clark Motor Car Company have leased temporary quarters in the Coliseum skating rink, where they will install machinery to carry on their business until the large plant now in course of construction is ready for operation.

WATERLOO, IA.—The Peters - Rockwell Auto Company, agents for the Cadillac, have secured the building opposite the Ellis Hotel which was formerly occupied by the Corn Belt Auto Company. The firm is composed of A. H. Peters and D. G. Rockwell.

BOSTON, MASS.—The Studebaker Brothers Company have awarded a contract for the erection of a two story and basement reinforced concrete garage on Cummington street. The building will be 171×50 feet, with a capacity for 120 cars. It will be ready for occupancy on January 1.

COLUMBUS, OHIO.—A number of changes in the Columbus and central Ohio agencies are to be made soon. The F. H. Lawell Company, which has been agent for the Franklin, and which conducted a general garage business on South Third street, will be succeeded by the Franklin Motor Car Company, recently incorporated with a capital of \$10,000, and will occupy a new building at Spring and Fourth streets, which will be completed soon by Caleb L. McKee. The building will be fitted up especially for

the agency, and will be quite elaborate. It will not conduct a garage business, but will maintain a repair shop and testing department. F. H. Lawell will be general manager. Associated with him will be S. D. Morgan and C. T. Phillips.

Houston, TEX.—The Houston Country Club will build a garage.

MINOT, N. DAK.—L. C. Eby has leased the Tompkins garage for two years.

Denver, Col.—J. H. Howard is building a \$2,000 garage at 800 Pennsylvania avenue. Foley, Minn.—A. V. Stimier will convert the creamery building into an up to date garage.

OMAHA, NEB.—Sweets-Edwards Automobile Company plan to erect a garage on Farnum avenue.

OKLAHOMA CITY, OKLA.—The Lee Motor Car Company have taken larger quarters at 27 West First street.

ONTARIO, CANADA.—The Imperial Motor Car Company will erect a garage at 85-93 East Richmond street.

New HAVEN, CONN.—Wm. T. Dill will erect a 44x110 feet brick garage at 398 Crown street, near Howe street.

ATLANTA, GA.—The Piedmont Motor Car Company, agents for the Parry "30," will open a garage and showrooms at Ivy street and Auburn avenue.

SACRAMENTO, CAL.—Fred T. Kitt will build a garage for electric vehicles exclusively. He is agent for the Columbus and Waverley electric lines.

Los Angeles, Cal.—Mountain & Carrigan, agents for the Royal Tourist car, moved into their new garage and salesrooms on Olive street last week.

PHILADELPHIA, PA.—Irwin & Leighton were granted permits for four one story garages, each 40x110 feet, at Nos. 330 to 340 South Broad street, to cost \$27,000.

GRAND RAPIDS, MICH.—Work on the Dwight garage at 172-4 North Ionia street is nearly completed. The upper floor is occupied and the lower floor will be ready for occupancy in a few days.

CHICAGO, ILL.—Wm. T. Maypole has purchased a plot of land, at a cost of \$100,000, on which he will erect a building suitable for the automobile industry.

Indianapolis, Ind.—An agency for Frayer-Miller trucks has been established here by W. D. Cost and P. M. Orlopp. A building at 224-226 South Pennsylvania street has been leased and converted into a garage and salesroom. The Rambler Automobile Company, Indianapolis representatives for the Rambler, has also taken temporary quarters in the building.

INDIANAPOLIS, IND.—Temporary quarters of the Indianapolis sales branch of the Maxwell-Briscoe Motor Company have been moved from 320 East Market street to 416 Massachusetts avenue, in the building recently vacated by the State Automobile Company. The company is building a \$60,000 building at Vermont and Illinois streets, which it will occupy in about three months. The Peck Motor Car Company, Indiana representative of the Cadillac, has moved

from 25 East Ohio street to Motor Row in North Delaware street.

OMAHA, NEB.—Byron Reed Company will build a brick garage at 1912-1916 Farnam street, to cost \$10,000.

NEW YORK CITY.—The West End Garage Company have taken a lease of the building at 574-576 West 130th street.

BUFFALO, N. Y.—Oliver N. George, 371 East street, is to build a one story concrete block public garage, to cost \$2,000.

CEDARVILLE, N. J.—The garage of Dr. W. P. Glendon was destroyed by fire on November 1. A defective flue was the cause.

ROCKFORD, ILL.—Savage & Love Company are preparing plans for the erection of a 90x50 foot garage at 650 South Main street.

PITTSBURG, PA.—W. H. Cassidy has obtained a permit to build a one story brick garage at 622 St. James street, to cost \$2,000.

New HAVEN, CONN.—Wheeler & Wuestefeld have moved into their new garage and repair shop at Commerce and Temple streets.

SUFFERN, N. Y.—A fire in the garage of C. J. Ryan destroyed the building, together with three automobiles and seven thoroughbred horses.

ATLANTA, IA.—Ground has been broken for the erection of a garage on Walnut street, between Fourth and Fifth streets, for Albert Johnson.

CLEVELAND. OHIO.—Kredley & Bowlus have been granted a permit to build a garage at East Eightieth street and Carnegie avenue, S. E., to cost \$4,000.

Los Angeles, Cal.—A \$15,000 garage will be erected for Wm. Garland on the west side of Olive street, between Twelfth and Pico streets, in the near future.

PORTLAND, ORE.—O. E. McCarthy, of the Portland branch of the Locomobile Company, has recently established branches for both the Locomobile and Oakland cars in Medford, Eugene and Salem.

SPARTANBURG, S. C.—E. T. Cantrell and Chas. Parker will erect a 72x40 foot garage on King street. Mr. Parker is proprietor of the Spartanburg Automobile Company, agents for the White Steamer.

LOGANSPORT, IND.—M. E. Cline has sold the Broadway Garage to Carter & Moore. Mr. Cline will retain his lease on the building, but the stock and equipment will be turned over to the new proprietors.

JERSEY CITY, N. J.—Work is progressing rapidly on the \$50,000 garage of the Crescent Automobile Company at 2565 Hudson boulevard. This new garage will provide accommodations for 250 machines.

INDIANAPOLIS, IND.—Forest and Howard Cummings have bought the Alfey garage on Pike street, where they will conduct a modern garage. The new firm will have the agency for the Ford, Regal and Premier cars.

BANGOR, ME.—Harry Chapman and T. D. Bailey have purchased a 114x66 foot plot between Union and Hodgdon streets, on which they will erect a three story garage and machine shop. The building will be

centrally located, and house 100 machines. The repair shop will be in the basement, where a supply of auto accessories will be kept on hand.

BEATRICE, NEB.—Victor E. Lang has become secretary, treasurer and general manager of the Beatrice Automobile Company, which recently moved into its new garage on North Fourth street.

NEWARK, N. J.—R. M. Terry, the local Palmer-Singer agent, has taken a long term lease on the property at 38 William street, corner Halsey street. The building is freproof and comprises a fine showroom.

Youngstown, Ohio.—The Interstate Automobile Company, which has taken over the agency for Ford cars in Mahoning, Lawrence and Trumbull counties, will open a garage and salesroom on Front street, near Champion street.

WILMINGTON, OHIO.—Minard Stephens has disposed of his interest in the Wilmington Garage to his partner, James M. West The concern will be incorporated under the name of the West Automobile Company as soon as preliminaries can be arranged.

GOSHEN POINT, CONN.—Edward S. Harkness has let the contract for the erection of a 100x110 foot, two and a half story fire-proof garage on his estate. The exterior will be of limestone and marble. One wing of the building will have a billiard room, a squash court and bowling alleys, the garage occupying the centre of the front. The approximate cost is said to be \$150,000.

# New Metropolitan Sales Organization.

William L. Colt, who organized and was president of the Cleveland Motor Car Company up to two years ago, and Harry L Stratton, who has been vice president of the Amalgamated Copper Company for several years, have organized the Colt-Stratton Company, and opened a salesroom at Broadway and Sixty-eighth street, New York. Mr. Colt is president of the new company, Mr. Stratton vice president and treasurer and Sydney H. Veal, formerly secretary of the Cleveland Motor Car Company, is secretary. The company will handle the new Cole "30" in the entire Eastern territory of the United States, and the Paige-Detroit in New York city and vicinity for a radius of 50 miles.

#### Ford Branch Managers Meet.

Branch managers of the Ford Motor Company held their annual convention at Detroit November 1 to 3. The report for 1909 showed an increase of 60 per cent. in the sales over the preceding year. On November 2, in the afternoon, the new factory was inspected, and during the evening a smoker was given at the Hotel Pontchartrain, followed by a Dutch lunch. On Wednesday night a banquet was served at the Country Club, at which J. W. Anderson acted at toastmaster. During the meeting the establishment of new Ford branches in Pittsburg, Cincinnati, Dallas and Omaha was announced.

#### Motorcycle Exhibits.

(Continued from page 542.)

pulley. This pulley is arranged to swing around the motor shaft as a centre in order to tighten the belt. This movement is obtained by a crank conveniently placed to the hand of the rider. The transmission of the 3 horse power twin is by a V belt direct to the rear. The 4 horse power, however, is provided with a two speed gear and a free engine clutch. All models are equipped with magneto ignition. Another interesting feature is the spring fork, which is of the link type, but the side rods telescope, and together with the links and stationary forks form triangles on both sides.

#### THE GREYHOUND MOTOR WORKS,

Buffalo, N. Y.—The motor of this machine has quite a number of special features. In the first place the flywheel is especially large, thus enabling the motor to run smooothly at slow speeds. The flywheels and crank pin are permanently assembled, and a connecting rod of the marine type is used. An option is given on V belt drive or a flat belt with idler. A spring fork of the parallel link type is used. In addition to this a spring seat mast is used just back of the brace, which would ordinarily act as the seat mast. Another feature is the method of holding the tank between the two horizontal tubes. This is accomplished by lugs clamped to both sides of the horizontal tubes. This avoids drilling of the frame tubes, and the consequent tendency to weaken them.

# THE MERKEL-LIGHT MANUFACTURING COMPANY,

Pottstown, Pa., show four machines, one a 23/4 horse power, single, with chain drive; two 4 horse power single, one with battery and the other with magneto ignition, and a 6 horse power twin. The three last named are equipped with V belt drive and the motors are ball bearing. A special feature of these machines is the use of an automatic pump oil feed which feeds the oil to the crank case and which has an adjustable stroke. The cam which actuates this is driven by means of a ratchet attached to one of the exhaust valve rockers inside of the cam shaft. This feature has now been in use for a year, and has given excellent satisfaction in use.

# THE CONSOLIDATED MANUFACTURING COMPANY,

Toledo, Ohio, manufacture the Yale motorcycle which they exhibit. The main improvements for 1910 are the use of a 55 inch wheel base and of a special design of drop frame. This year an option is given on a flat or V belt drive. If the former is chosen a special type of adjustable spring idler is provided. The singles are made in 3½ horse power, and equipped with either battery or magneto ignition. The twins are rated at 6 horse power, and are equipped with magneto ignition. The standard finish for these machines is French gray.

#### THE HARLEY-DAVIDSON MOTOR COMPANY.

Milwaukee, Wis., have three machines on exhibition, a 7 horse power twin and two 4 horse power singles, one being equipped with battery and the other with magneto ignition. This machine uses a flat belt for transmission, which on this model has been increased to 1¾ inches in width. Another radical improvement is the use of a new type of idler of ingenious construction, which is well protected from injury in case of a fall. The cooling flanges have about one-fifth more surface than in 1909.

#### MILTON W. ARROWOOD COMPANY,

Atlanta, Ga., are agents for the Wagoner motorcycle, built by the Wagoner Motor Cycle Company, of St. Paul. This machine is built along standard lines, with a 3 horse power motor and V belt drive. About the only change in the 1910 model is the use of 2½ inch tires in place of 2½ inch.

#### THE EXCELSIOR SUPPLY COMPANY,

Chicago, Ill.—This concern have on exhibition the Excelsior motorcycle. Besides this they carry a good line of both automobile and motorcycle sundries and accessories.

#### Tires and Tire Sundries.

THE FISK RUBBER COMPANY,

Chicopee Falls, Mass., have an exhibit of their regular types of bolted-on tires as well as a line of clincher tires of their manufacture. They are also showing and demonstrating their demountable rim. A feature of their exhibit is a 40x6 inch Fisk tire on a demountable rim, which is said to be the largest tire in the show, and is used on fire apparatus when high speed is desired.

#### MORGAN & WRIGHT,

Detroit, Mich., have a very extensive line of both motorcycle and automobile tires. A novelty in the latter line is their "Nobby" tread, a rubber non-skid formed of long rounded projections laid herringbone fashion on the tread. Another novelty in the tread line is a motorcycle racing tire which is a combination of the well known Bailey and corrugated treads. The corrugations are in the centre and the round projections at the sides. When the wheel inclines in rounding a corner the projections are brought into play to prevent side slip.

#### THE MICHELIN TIRE COMPANY,

Milltown, N. J., show a full line of their tires, both non-skid and plain, in standard clincher and quick detachable styles. They also show their quick detachable and touring demountable rims. A product which they are featuring this year is Michelin Mastic, which is used for repairing cuts in casings, and also for repairing punctures in inner tubes without the use of patches. They also have a complete line of their various tire tools.

#### THE REPUBLIC RUBBER COMPANY.

Youngstown, Ohio.—The special feature exhibited by this firm is their rubber non-skid tire. This has been in use now for a considerable time, and is said to have proven remarkably satisfactory. It is provided with oblong projections with rounded ends placed along the circumference of the tire. These are hemispherical in section. This, as well as plain treads, is shown in both clincher and quick detachable forms.

#### THE AJAX-GRIEB RUBBER COMPANY,

Trenton, N. J., call particular attention to the 5,000 mile guarantee which accompanies each tire. Their rubber non-skid is another point which they are featuring. In this the tread is crossed in both directions by deep V shaped lines, thus forming lozenge or diamond shaped projections.

#### THE FEDERAL RUBBER COMPANY,

Trenton, N. J., feature their rubber nonskid tire. This is of the type with projections on the tread. In this case they take the form of Maltese crosses, which are placed in rows. These are carried in both clinched and quick detachable types. Besides this there is also carried a line of plain treads.

#### FIRESTONE TIRE AND RUBBER COMPANY,

Akron, Ohio, show their regular line, which includes their rubber non-skid, which has the word "Firestone" in raised letters placed diagonally across the tread of the tire. They are also showing their demountable rim, which has now been on the market for a year. While it has undergone no radical changes, one or two minor improvements made greatly facilitate a change on the road. This rim can be supplied either for clincher or quick detachable tires. When supplied for the latter it may be used as such while on the wheel without reference to the demountable feature.

#### THE HARTFORD RUBBER WORKS COMPANY,

Hartford, Conn., show their regular line and have nothing at present particularly new. They are, however, featuring their Wire Grip non-skid tire. This is carried in both the Dunlop and standard clincher and quick detachable types, as well as in solids for truck use.

#### THE GOODYEAR TIRE AND RUBBER COMPANY,

Akron, Ohio, make a feature of their air bottles. The use of the same is demonstrated by means of an air tube connected to one of them, which also has another valve attached to it, through which the air can be allowed to escape once the tire is inflated. They also have a full display of their regular line, which is well known.

#### THE EMPIRE TIRE COMPANY.

Trenton, N. J., are for the first time exhibiting their new demountable rim. The clamps which hold the rim in place are so arranged that after the nuts are loosened about five turns they can be turned out of the way, thus doing away with the necessity of removing either them or the nuts from the wheel. This greatly facilitates a change on the road. Another feature of this firm is a butt ended motorcycle tube. They also have a complete line of tires of both the quick detachable and clincher type.

#### THE G & J TIRE COMPANY,

Indianapolis, Ind., show their full line of automobile and motorcycle tires, as well as a line of motorcycle grips, lamp connections and equalizing chambers. In addition to this they have tire tools, cement, acid cure solution and blow-out patches.

#### THE DIAMOND RUBBER COMPANY,

Akron, Ohio, exhibit both standard clincher and quick detachable tires to fit all leading makes of rims, and with various types of tread. They also carry a line of solid buggy tires. A new product of this company is a line of both high and low tension ignition cable. They are also showing their improved Marsh rim, which is greatly simplified and strengthened. In addition to this they have their demountable rim on exhibition, which has undergone radical changes.

#### JAMES L. GIBNEY & BROTHER,

Philadelphia, show the Auto-Electric vulcanizer, which is adapted to be used with either alternating or direct current for mending cuts in tires, as well as punctures in inner tubes. They also show a "wireless" tire, in which a hard rubber base is dovetailed into a steel band, the soft rubber tire proper being secured to the hard rubber base.

THE UNIVERSAL TIRE PROTECTOR COMPANY, Angola, Ind., show their emergency tire sleeve, which is of steel studded leather. It is secured in position by a very ingenious ratchet winding arrangement known as the universal anchoring device. They also have a full steel studded tread which has a special attaching device original with this firm.

#### THE LEATHER TIRE GOODS COMPANY,

of Niagara Falls, N. Y., show an interesting new accessory in the way of tire saver mud chains-chains strapped in single lengths to the spokes, or complete chains mounted, as ordinarily, clear around the wheel, but strapped with an automatic ightening band to the spoke. Neither chain, it is claimed, will slip under any condition. Neither will they hurt the tire, because of the protection afforded by the heavy thickness of chrome-tanned leather between iron and rubber. This protection. the company claim, makes their single length chain practicable. The chrometanned leather is used also in the straps. It is unaffected by water. The exhibit also included the Woodworth tire protector of the company's manufacture.

#### THE B. F. GOODRICH COMPANY,

Akron, Ohio, exhibit their full line of both solid and pneumatic tires of all kinds.

They are featuring their so called "Wireless" tires for trucks and other heavy vehicles. In this tire the tire is formed on a steel band with circumferential dovetail grooves. In these grooves is affixed a band of hard rubber onto which the soft rubber or tire proper is vulcanized. The tire is secured to the wheel so that it may be easily removed when it becomes worn. Another features is their Palmer-Webb tire, which is designed especially for electrics with the idea of giving increased mileage.

THE KING LEATHER TIRE COMPANY,
Racine, Wis. This tire, which is of the metal studded, anti-skid type, is covered completely with leather from the fabric outward. This, it is claimed, not only makes the tire more immune from punctures but also adds so much to the strength of the same that it is practically immune from blow-outs and rim cuts. The section of the tire seems to show that considerable thought his been given to its construction.

#### THE RUTHERFORD RUBBER COMPANY,

of Rutherford, N. J., present a complete display of Sterling automobile plain tread tires and blue tubes, each shown complete and in sections. Sections of Sterling solid rubber tires for buggies are also shown. The blue outer finish of the tubes is claimed to prevent air checking or cracking when the tubes are folded in boxes. The splicing of these is done diagonally, with the valve passing through both of the splices. The whole tube is vulcanized.

#### Accessories.

THE UNITED MANUFACTURERS, NEW YORK.

WEED CHAIN TIRE GRIP COMPANY.—No radical changes were shown in this line, with the exception that the cross links are now case hardened. The regular line of chains was shown, and the equalizing device.

THE NEW YORK AND NEW JERSEY LUBRICANT COMPANY showed their line of non-fluid oils, as well as a line of motor cylinder oils. As usual, they had at their stand a transmission with glass covered case to show the action of their non-fluid oil.

C. A. MEZGER shows his line of automatic wind shields, which have had no radical changes made in them for the past year. He also shows the original Mezger "Soot Proof" spark plug.

THE JONES SPEEDOMETER COMPANY.—A new line introduced this year is a line of motorcycle speedometers arranged to be fitted to the handle bar. These are made in various models, with and without trip, and total odometers, and with and without maximum hands. A new product of this firm is the Jones electric horn, which is of the type employing an electrically operated vibrating sound producing device. Another novelty is a combination bulb and electrical horn in one instrument, with a common bell. The object of this combination is to

provide a hand horn in case of the battery being run down.

THE CONNECTICUT TELEPHONE AND ELEC-TRIC COMPANY.—This concern show their regular line of coils, timers, switches, etc. Their battery and magneto switch has been improved in its mechanism so that when the plug is partially withdrawn the battery will not be grounded. They have, however, brought out two entirely new lines. One of these is a master vibrator coil. The master vibrator of this coil is made double, so that in case of one of the vibrators getting out of order the unit to which the master vibrator is affixed can be withdrawn and turned end for end, and replaced. This brings the other vibrator into action. Buttons placed on the tops of the coil units are used to cut out the ignition from any individual cylinder for testing purposes. The Type X coil was brought out to meet the demand for a low priced coil. In this coil the units are enclosed in a hard rubber cylindrical case with a square top. The connections are made by bands which surround the cylindrical case. It is therefore impossible to put a unit into the box the wrong way.

#### HERZ & CO.

show their Bougie-Mercedes plug, with insulation formed from imported stone, that (it is claimed) will not crack under heat, and consequently will not short circuit. They also show the new pattern Herz timer, fitted with a ball bearing roller. Another detail is the Herz distributor, with its spring detachable terminals and snap contact.

#### RANDALL-FAICHNEY COMPANY.

of Boston, feature their exhibit of the new "Jericho" horn, known as the "road clearer," operated by the exhaust, and for which the most lusty voice among all horns is claimed. This was put on the market last spring. A model of the horn, 5 feet high, electrically illuminated, is on exhibit, with normal size models. It is claimed that this horn can be heard a mile against the wind. and 2½ miles with the breeze.

#### CLOUD-STANFORD COMPANY,

of Atlanta, the toggery outfitters, have a classy exhibit of personal apparel and equipment for motorists. They show largely from the well known line of the Scandinavian Fur and Leather Company, New York for whose goods they have the exclusive local agency. Their exhibit is made up of garments and personal equipment for owner and chauffeur—gloves, caps, goggles, Thermos bottles, lunch baskets, robes, coats, etc. and sweater coats of the American Hosiery Company.

#### THE POST & LESTER COMPANY.

Hartford, Conn., feature in their exhibit the Volier and Rival automobile horns. They also make an attractive and convincing display of their ignition cable, which they furnish to many manufacturers. The company's line of automobile clocks—Luna,

Sterling, Venus and Imperial—is also shown. The company's lamp and generator equipment, adjustable to all makes of cars, is presented. Their red rubber horn bulb, claimed as of purer and better wearing material than black rubber bulbs, is shown, with an excellent line of tire covers and lamp covers.

#### THE SPRAGUE UMBRELLA COMPANY,

of Norwalk, Ohio, exhibit an attractive line of vehicle and automobile tops, canopies and wind shields. Among these is their new 1910 model of "rain vision" shield, which can be set at any angle in four positions. Their demonstration shows the seamless drawn tubing of which the shields are formed, and also the flush joints of the connections, which eliminate any bolts in the way of cleaning and polishing. Another feature claimed for the wind shield is that the lower part of its metal frame covers the filler board, leaving no crack for soap and water to enter.

#### CHARLES E. MILLER.

of New York, claiming to be the largest automobile supply house in America, with ten branches in as many principal cities of the country, shows extensively. The firm's latest branch has just been opened in Atlanta. This exhibit shows numerous details of accessories. Among them are Brampton chains and Miller porcelain spark plugs. The exhibit shows a full line of automobile and motor boat supplies.

#### WHEELER & SCHEBLER,

of Indianapolis, are on this floor with a complete exhibit of all their various models of carburetors, including their new racing model. This company, in addition to its participation in the show, also has a corps of factory experts in attendance at the Speedway events in Atlanta. The exhibit's proud claim is that there are over twenty makes of car in the show equipped with Schebler carburetors. Wheeler & Schebler magnetos are also shown.

#### THE C. A. SHALER COMPANY,

of Waupun, Wis., presented an interesting exposition of their complete line of Shaler electric vulcanizers, adapted to be operated on ordinary city current. The claim for these machines is that they can do any work that is practicable on any size of automobile tire, inner tube or outer casing. The latest addition to the Shaler line was shown—the first motorcycle tire vulcanizer in the market. This is operated on the same principle as Type C of the Shaler automobile tire vulcanizer, applying the heat on the inside of the tire where the new fabric is placed and obviating the necessity for cutting away any of the rubber in the tread, as would be necessary if the heat were applied to outside.

#### THE HARTFORD SUSPENSION COMPANY, New York city, manufacturers of the Truffault-Hartford shock absorbers, have made no material changes in this line for the past year. As on former occasions, they have

tried to make their exhibit interesting by some novel method of demonstrating their product. This year it takes the form of two small model automobiles, about one-ninth size, one equipped with the device, the other without it. These are both run on small rollers, with jounces on them of equal size. The difference in the riding quality is quite marked. The miniature shock absorbers fitted to the model car are a work of art, being an exact reproduction in every way of the full sized article.

#### JOSEPH DIXON CRUCIBLE COMPANY.

Jersey City, N. J., show a full line of their graphite lubricating compounds suitable for the lubrication of various parts of the mechanism, from chains to gear cases and the leaves of springs. To illustrate the action of their gear lubricating compound they have a gear box in operation with glass

THE SHIPMAN'S INSTRUMENT COMPANY, of Sunbury, Pa., show their interesting new meters that "tell how long, how fast, and how far." Several working models were shown, all on the same speed, and each checking the other with striking accuracy. These instruments, known as the Shipman speed indicators, show trip mileage, trip hours, season mileage, season hours and speed, all on the same face, and all with the same machine. Their slow moving parts are one of the strongest features. They are operated on the escapement principle, which enables them to show the average speed for each one-thirtieth of a mile.

#### W. F. POLSON.

of Buffalo, N. Y., displays his wind shields in various models. The use of channel rubber for cushioning the glass of these shields is a new feature. This cushion is to allow for the contraction and expansion of brass frames. Model M. for storm use, adjustable to an angle leaving a crack for vision, was shown. This model is also adaptable at an opposite angle to sultry weather use, for sending a draught back into the car and at the same time avoiding dirt and dust. The Polson automatic was shown, demonstrating its freedom from moving parts and its flush construction.

THE WARNER INSTRUMENT COMPANY, of Beloit, Wis., exhibit their new 1910 Warner Auto-Meters, with their new special feature of an inner electric light, which is operated by a push button on the body of the car, and obviates much of the inconvenience experienced heretofore in traveling after dark on road readings in a strange country. This is fitted on all the new models of Warner Auto-Meters. Another strikingly new feature of the 1910 Warner instruments is their showing of total mileage up to 100,000, instead of the 10,000 total mileage limit prevailing till now.

THE CHICAGO WIND SHIELD COMPANY, of Chicago, show their "Adjusto" model, with its split filler board that allows it

to go flat over the hood. One of the salient features of this shield is the protection of its springs in tubes. Another is the break in its adjustment, obviating all danger of slamming and consequent breakage of the glass. The "Dixie" model is adaptable to storm and weather use, being constructed with a double fold that permits it to be collapsed inward under the steering wheel.

# THE GABRIEL HORN MANUFACTURING COMPANY,

Cleveland, Ohio, one of the pioneers in the manufacture of horns of the exhaust blown type, show their regular line, and besides their new four tube horn, known as the Gabriel trumpet. This is a horn operated by keys so arranged that all the bugle calls used in the United States Army can be played on it. They also have a ten note "music horn," which can be used to play almost any of the simpler melodies. They are also showing the Foster shock absorber.

#### WILLIAM CRAMP & SONS,

of Philadelphia, exhibit in ingots and castings their manganese bronze and Parsons white brass metals. They are now being used largely in automobile construction. A number of complicated castings by the Wetherill Finished Castings Company were exhibited in these metals—crank cases, automobile axles, connecting rods, transmission cases, etc., of the models that are being used in Standard cars.

#### THE SIRENO COMPANY,

of New York, show a full display of their electrically operated automobile horns, known as the "mile-ahead" horns. These were shown with and without the projectors. All of the models are on the Sireno principle, but in the larger horns is demonstrated the magnetic brake that eliminates the siren sound, making a straight and powerful electric voice of one note.

THE STROMBERG MOTOR DEVICES COMPANY, of Chicago, exhibit their carburetors only, showing several different models, both in complete form and in assembly parts. Their new Type C, which has been out only a couple of weeks, has a double jet gasoline nozzle, and is especially designed for six cylinder motors. They show also their regular line of water jacketed and non-water jacketed carburetors.

THE NEVER-MISS SPARK PLUG COMPANY, of Lansing, Mich., exhibit a full line of their plugs, and also a line of electrical instruments manufactured by them—ammeters and voltmeters and combination voltammeters. They also showed their automobile clocks, among them being one of special design fitted for attachment to steering wheel spokes, so as to keep it directly before the driver.

#### LAVALETTE & CO.,

of New York, exhibit their direct high tension Eisemann magnetos in several different models. One special display was of the magneto fitted with oscillating advance magnets rotating about the armature, instead of advancing the cam. The claim for this is that the range of spark timing is unlimited. The Eisemann special spark plug with platinum spiral was also shown.

#### S. F. BOWSER & CO.,

of Fort Wayne, Ind., show a varied line of their product. They present representative outfits from their automobile accessories department for private and public garages, and limit their display to garage equipment. They show their portable and stationary gasoline tanks, their oil tanks—self measuring and fireproof—and their pump meters and filters.

#### THE NATIONAL CARBON COMPANY,

Cleveland, Ohio, have on exhibition a full line of their dry batteries of all shapes and sizes, both singly and in groups. The feature of their exhibit is their demonstrating or testing board, designed to show the characteristics of various ignition systems using batteries for ignition, both as to battery economy and synchronism of the spark.

#### ADAM COOK'S SONS,

New York, show their well known line of Albany tallow grease, with a side demonstration of their grease cups. This grease, which has been forty-one years on the market, needed no great introduction, as it is claimed that "you can get it anywhere in the United States."

THE VEHICLE APRON AND HOOD COMPANY, Columbus, Ohio, exhibit their Gordon tire covers, with a comprehensive display of automobile fabric supply goods—tire covers, trunks, muff and foot robes, plain robes, radiator covers, luggage bags, lamp covers, top dust hoods, etc.

#### THE HAVOLINE OIL COMPANY.

of New York, show samples of their oil, exhibiting also a complete display of trade packages in which their wares are retailed. They claim a high fire test for this oil, and the lowest percentage of carbon on the market.

#### . THE OLIVER MANUFACTURING COMPANY,

Chicago, Ill.—The Oliver jack is of the double ratchet type, a motion of the lever either up or down lifting the car. They are made in various heights, from 10 to 13 inches, and with a lift of from 7 to 9 inches. The handle is so formed as to make a good tire tool in case of necessity.

#### COLUMBIA LUBRICANTS COMPANY.

Monogram oils were shown by the Columbia Lubricants Company, of New York, as a straight line product from Pennsylvania crude lubricants. These gas engine cylinder oils are attractively displayed in sample tubes under glass and in trade packages.

#### THE BADGER BRASS COMPANY,

Kenosha, Wis., exhibit their very complete line of acetylene gas lamps and generators, electric side and tail lamps and oil side and tail lamps. Their exhibit, which is one of the very few lamp exhibits at the show, is located on the main floor and is in charge of W. C. Marion.

#### C. F. SPLITDORF.

of New York, exhibits his ignition specialties, including high tension magnetos, coils. timers, spark plugs, etc. The firm features its magnetos, which are made in quite a variety to suit different requirements. The claim is made that these operate so low a speed that a battery auxiliary is unneccessary.

### THE AJAX TRUNK AND SAMPLE CASE COMPANY.

of New York, show an attractive array of automobile touring necessities in their line. Among the details is a trunk, made in any shape and color to harmonize with requirements, fitted to contain two, three or five individual dress suit cases. The Ajax tire trunk is also shown, fitted with the new arch steel rim and steel clamps, for protection and security. They show, too, their demountable rim trunk, with its flat top allowing space for the valve of the rim, and with a handle permitting its being carried like a suit case from the car.

#### THE VEHICLE TOP AND SUPPLY COMPANY.

St. Louis, Mo., have on exhibition a touring car top on ordinary lines, as well as a special top known as the Du Quesne, for use on runabouts or roadsters with long raked steering columns, where it is desirable that the top should extend well to the front and yet give clearance near the seat for easy entrance.

#### THE PHANSTIEL ELECTRIC LABORATORY,

of North Chicago, Ill., show a line of ignition goods, including coils fitted with a vibrator of their own design using a stretched helical spring. They also show the Phanstiel magneto, which employs a separate transformer coil located in the bend of the magnets. The features of this magneto are easy removal of the circuit breaker for inspection and adjustment and the robustness of its parts.

#### THE LUTZ & LOCKWOOD COMPANY,

Aldena, N. J.,—The exhibit of this concern consists of the "S-X" ignition dry cell and the "S-X" magneto. This latter is novel in respect to the arrangement for four cells. Two transformer coils are used, one having its secondaries connected to cylinders Nos. 1 and 4, and the other having its secondaries connected to Nos. 2 and 3. Two circuit breakers placed opposite each other are employed, one operating one coil and the other the other.

#### THE STANDARD AUTO SUPPLY COMPANY

have a very large exhibit of all kinds of sundries and accessories for machines, including ignition accessories, plugs, timers, magnetos, etc., as well as goggles and radiator ornaments, etc. Among these are two comparatice novelties. The "Reliable Trouble Hunter" is a small lamp with reflector which

can be attached to the forehead by means of a rubber band. The safety air tire gauge consists of a self fastening tire connection fitted with a Schrader pump connection on one side and a simple plunger gauge on the other. Another novelty is the Le Tesophone four note bugle horn.

#### THE NEWARK RIVET WORKS.

Newark, N. J., show their folding friction wind shields. The upper part is retained at any angle with the lower by means of an ingenious friction joint formed between fibre and maplewood washers. It is claimed that this will hold in practically any position that it may be put.

#### THE WARNER TOP AND POLE COMPANY.

Cincinnati, Ohio, make automobile tops in great variety. Owing to lack of space they had none of their completed tops on exhibition, but showed various parts in different stages of manufacture, as well as cuts of completed tops.

#### THE CARTER-CRUM COMPANY,

show a line of autographic registers which are suitable for keeping garage accounts or those of repair shops, etc. A peculiarity of this make is the fact that the copy which is kept in the machine is cut off from the reel and filed away on a spindle.

# Henry Motor Car Company Secceeds Gary Company.

The Henry Motor Car Company, of Chicago, will succeed the Gary Motor Car Company, for whom the Chamber of Commerce of Muskegon, Mich., erected a factory in that city. W. L. Simonton, of Chicago, is president of the new company, and D. W. Henry, who was formerly connected with the Electric Vehicle Company, of Hartford, Conn., will be general manager. The factory building which has been erected is 500 feet long by 125 feet wide. Machinery will at once be installed, and it is planned to turn out 1,000 cars by August 1 next. Only a single type of four cylinder chassis is to be manufactured, which will be fitted with different types of bodies.

# Elwell-Parker Company Absorbed by Anderson Carriage Company.

The Elwell-Parker Electric Company, of Cleveland, Ohio, have been absorbed by the Anderson Carriage Company, of Detroit. Mich The former firm manufactures electric motors for vehicles, etc., and the latter electric carriages. The Elwell-Parker plant in Cleveland will be continued in operation, and M. S. Towson, who has been with the firm since 1902, becomes general manager of this plant, and also consulting engineer to the Anderson Carriage Company, acting in an advisory capacity with George M. Bacon, the designer of the Detroit Electric. The capital stock of the Anderson Carriage Company has been increased from \$500,000 to \$1,000,000. A production of 1.500 complete power plants at the Cleveland works is contemplated for next year.

### NOTES OF THE INDUSTRY AND THE SPORT.

#### Miscellaneous Notes.

The Studebaker Automobile Company, South Bend, Ind., have decided to make a separate department of their electric vehicle work.

The Scranton (Pa.) A. A. has made a grant of \$2,000 to the borough of Moscow to aid it in the construction of a new main road through the borough.

The American Motor Company, of Brockton, Mass., have begun work on a two story 100x50 foot addition to their plant, and plans are in hand for another addition of the same size.

The capital stock of the King Leather Tire Company, with works at 3417-3419 Vliet street, Milwaukee, Wis., has been increased from \$20,000 to \$40,000, to carry the increased production.

It is stated that 103 members of the Motor and Accessories Manufacturers will this year exhibit at the Grand Central Palace Show, who will occupy floor space to the extent of 14,870 square feet, practically the same as last year.

A hill climb on the well known Edgewater Fort Lee hill opposite New York is being planned for Thanksgiving Day to celebrate the repaving and resurfacing of the hill. The Edgewater (N. J.) Motoring Society is promoting the event.

A meeting of business men was held at the office of the Buick Motor Company in Flint, Mich., on October 29, for the purpose of forming a \$500,000 organization to provide workmen's dwellings, for which there is a great demand in Flint at present.

The E. R. Thomas Motor Company, of Buffalo, have decided to use steel flywheels on their 1910 motors, and have placed an order for same with the Carnegie Steel Company, of McKeesport, Pa. The flywheels will be made in the Homestead plant by the Slick process.

The National Motor Vehicle Company, of Indianapolis, is erecting a building that will be used exclusively for office purposes. It is to be a two story frame and stucco structure, 25x100 feet, and will cost about \$10,000. A large addition is also nearing completion, and the National output next season will be 600 cars.

W. W. Ker will give a series of public lectures on automobile subjects at the Hebrew Technical Institute, 36 Stuyvesant street, New York, as follows: November 22, "The Gasoline Automobile—Part I"; November 29, "The Gasoline Automobile—Part II"; December 6, "The Gasoline Automobile—Part III"; December 13, "The Electric Automobile."

The big carriage manufacturing concern of Racine-Sattley Company, Racine, Wis., is again said to be contemplating the addition of an automobile plant. Some time ago it was said that a car manufactured in

St. Louis would be built at Racine in the future, but it is supposed that the deal fell through. H. E. Miles, founder of the company, retired some weeks ago, and George H. Yule, of Kenosha, one of the owners of the Badger Brass Manufacturing Company, was named president.

A number of prominent automobilists in Washington, D. C., have organized the District of Columbia Good Roads Association, having for its object the improvement of the old stage road from the capital to Leesburg, Va. The project has met with favor among the farmers in the sections through which the road passes, and wealthy men who have residences nearby have promised to subscribe to a fund to defray the expense.

#### Club Notes.

The Florence (Col.) Motor Club has been organized with the following officers: W. E. Mitchell, president; Dr. L. E. Rupert, vice president, and E. F. Jack, secretary and treasurer.

An automobile club has been organized at Ocala, Fla., and the following temporary officers have been appointed: Edward Holder, president; Emmett E. Robinson, secretary, and David S. Woodrow, treasurer.

The Philadelphia A. C. plans to introduce a chauffeurs' employment bureau, keeping on hand a list of chauffeurs looking for positions, with their records, for the use of members of the club who desire to engage drivers.

The St. Paul (Minn.) A. C. has closed its summer clubhouse at the Anchorage on the St. Croix for the summer. The clubhouse and the roads in the vicinity will be improved at considerable expense for next season.

The A. C. of Philadelphia held its regular monthly meeting on November I, and elected twenty-eight new members, bringing the total up to 980. The touring information committee reported that it has published six road map sections to date.

It is reported that the Boston Motor Club, which was organized after the Boston show last spring as a result of dissensions among the members of the Bay State A. A., will pass out of existence, a proposal having been made to its members to join the Bay State A. A.

At a meeting of the contest committee of the Hartford (Conn.) A. C. on October 29 plans for an all Connecticut endurance contest to be held between May 15 and June 15, 1910, were discussed. The course will lead through practically every city of importance in the State. A technical examination of the cars both before and after the contest is contemplated. The contest committe of the club consists of Hiram P. Maxim, C. H. Gillette, H. W. Nuckols,

Albert M. Kohn, Samuel A. Miner and William C. Russell.

The Pittsburg (Pa) A. C. last week entertained about 200 township commissioners and road supervisors at its clubhouse, and paid bonuses offered by it for the use of the King road drag for the improvement of dirt roads. The first prize of \$100 was awarded to John Kirk, Broughton, Snowden Township.

Dr. J. F. Schreiber has been appointed chairman of the racing board of the Milwaukee A. C. President Clarke S. Drake has appointed James T. Drought, secretary of the Wisconsin State A. A., chairman of the committee on legislation, together with State Senator Julius E. Roehr, Alonzo Burt, George A. West and Emil O. Hoffman.

The Franklin County Automobile Association was organized in Greenfield, Mass., recently, with the object of promoting the improvement of roads in the county. The organization starts with about 100 members. The following officers were elected: Rev. C. W. Merriam, president; Dr. J. C. O'Brien, vice president; A. B. Allen, treasurer, and Dr. E. L. Major, secretary and clerk.

The Portland (Ore.) A. C. has received a shipment of road signs, which were erected along the different roads radiating from Portland last week. The signs consist of 36x5 enameled steel panels, with sharply contrasting figure on colored backgrounds. Signs of the same color will be erected along each route. The signs are carried on wrought iron standards 5 feet 6 inches high.

At its recent annual meeting the Hudson River Valley A. A., at Poughkeepsie, N. Y. elected the following officers for the ensuing year: Alva L. Peckham, Poughkeepsie, president; Rudolph F. Tompkins, Fishkill, first vice president; John Hopkins, Hyde Park, second vice president, Dr. J. W. Poucher, Poughkeepsie, third vice president; Charles G. Schwartz, Poughkeepsie, treasurer, and John J. Glass, Poughkeepsie. secretary. A motion was adopted in favor of the board of governors offering a reward for the apprehension of drivers who try to escape after injuring pedestrians. The authorities of Poughkeepsie will be urged to use less water in sprinkling the streets of the city, which are now so flooded as to be a danger to motorists.

#### Racing Notes.

The protest filed by the Atlas Motor Car Company, of Springfield, Mass., against the decision of Referee Wm. K. Vanderbilt, Jr., not to make an award in Class 2 of the Vanderbilt Cup entries has been rejected because it was not lodged within twenty-four hours as required by the rules, and, besides, the Atlas car had not completed the

prescribed twenty-two laps at the time the race was called off.

The Simplex car driven by George Robertson in his recent try-out on the new Speedway at Hopeville, Ga., has been purchased by Edward Inman, of Atlanta, and Robertson has been engaged to drive it in the events on the Speedway this week.

M. C. Moore, the newly elected president of the Wisconsin State A. A., is reported to be endeavoring to arrange plans for holding the Cobe Cup race on some circuit in Wisconsin next year. A circuit in the vicinity of Beloit has already been explored for the purpose. This year the race was held by the Chicago Automobile Club on a circuit in northern Indiana, but was not a success financially.

The Pope-Hartford car, driven by Jack Fleming, which won the free for all and the light car race in the recent Portola road races in California, was equipped with Fisk bolted on tires with Fisk removable rims. We are informed that three of the car's shoes were changed toward the end of the 258 mile contest as a matter of precaution, while one casing and its tube went through the entire race and finished in good condition.

#### Trade Personals.

WILL Soules, a well known racing driver, will have charge of the testing department of the Croxton-Keeton Motor Company, Massillon, Ohio.

CARL J. SIMONS, formerly manager of the Maxwell-Briscoe Kansas City branch, has accepted a similar position with the Dempster Machinery Company, who handle the Locomobile in Kansas City.

H. W. DOHERTY, whose resignation as sales manager of the Cameron Car Company of Beverly, Mass, we announced in a recent issue, has bought an interest in the Jordan Equitable Company, of Beverly, manufacturers of automobile accessories

STANLEY A. ALLEN, superintendent of the Packard Motor Car Company of New York, has resigned to become manager of Fickling & Co., succeeding C. R. Hough, who goes to Washington, D. C., to become sales manager of the Buick branch there.

C. H. TANGEMAN, president of the Hol-Tan Company, New York, who handle the Lancia car in this country, sailed last week for England, where he will visit the Olympia Show, and before returning will make a trip to the Lancia works at Turin, Italy.

JESSE FROEHLLICH, managing director of the Benz Auto Import Company of America, accompanied by Mrs. Froehlich, sailed for Europe yesterday on the Amerika of the Hamburg line. After visiting the Olympia and Stanley automobile shows in London, Mr. Froehlich will go to Mannheim, Germany, where are located the works of the Benz Company.

C. H. Tyler, who was formerly connected with the Studebaker Chicago branch, has been appointed manager of the electric pleasure vehicle department of the Studebaker Automobile Company, and will in

future have charge of all matters relating to electric pleasure vehicles, acting under the advice and counsel of General Manager Fames

#### New Incorporations.

The Only Car Company, Echo, L. I.—Capital stock, \$300,000.

The Lowell Auto Body Company, Grand Rapids, Mich.—Capital stock, \$30,000.

The Dixie Motor Car Company, Oklahoma City, Okla.—Capital stock, \$100,000.

The Toledo Motor Company, Toledo, Ohio, have increased their capital stock from \$10,000 to \$2,000,000.

Patton-Van Vliet Automobile Company, Des Moines, Ia.—Capital stock, \$20,000. Incorporators, D. T. Patton and G. Van Vliet.

The Vaughan Motor Company, Portland, Ore.—Capital stock, \$10,000. Incorporators, Walter H. Evans, Frank Carey and C. W. Vaughan.

Standard Motor Car Company, Spokane, Wash.—Capital stock, \$25,000. Incorporators, Frank W. Schultz, J. A. Stoner and M. E. Estep.

The Norwalk Consolidated Auto Company, Norwalk, Conn.—Capital stock, \$25,000. Incorporators, John W. Bull, Geo. N. Philbin and Theo. S. Glover.

Texas Motor Sales Company, Fort Worth, Tex.—Capital stock, \$20,000. Incorporators, H. E. Crowley, Ira W. Wood, K. O. Wright and B. K. Goree.

The Great Southern Automobile Company, Birmingham, Ala.—Capital stock, \$100,000. Incorporators, E. F. Enslen, Ike Adler, John Kyser and E. F. Enslen, Jr.

# Auspicious Opening of Atlanta Speedway—Records Fall.

The first day's events on the new Hopeville Speedway of the Atlanta Automobile Association on Tuesday proved a great success. In the presence of about 5,000 spectators Lewis Strang, driving the 175 horse power Fiat racer described on another page, established a new world's record for a two mile track, covering a mile in 0:37.7, which is equal to a speed of 95.5 m. p. h. This replaces the record established by Oldfield in a Benz racer on the Indianapolis track recently. Oldfield with a Benz made second best time in the time trials, viz., 0:40.13. While the time trials were perhaps the most interesting event of the day, a great deal of interest also attached to the 200 mile stock chassis race. This was won by Louis Chevrolet in a Buick, whose time was 2:46.48, which is equal to an average speed of 75.9 m. p. h. Both the second and third places in this race were secured by Chalmers-Detroit cars, driven by Dingley and Lorimer, respectively. The 10 mile stock chassis event for cars of from 451 to 600 cubic inches piston displacement was won by a National, driven by Aiken, in 8:27.22, and second place in the same race was also secured by a

National, driven by Kincaid, whose time varied from that of the winner by only a fraction of a second. The 10 mile race for light cars was won by Joe Matson in a Chalmers-Detroit, his team mate, Knipper, securing second place. In the to handicap race, the Marmon driver. Stillman who suffered bad luck in the recent Vanderbilt Cup race, was winner, he being allowed a handicap of 70 seconds. Stillman also took part in the 200 mile stock car race, and met with an accident on the eighty-fifth lap, which forced him to withdraw. This was the only mishap of the dav. The summaries follow:

One Mile Time Trial—First, Fist (Strang), 0:37.7; second, Benz (Oldfield), 0:40.13; think, Walter Christie, 0:43.82; fourth, Stearns (Ruberford), 0:50.35.

Ten Mile Stock Chassis, 451 to 600 cubic inches piston displacement—First, National (Alen), 8:27,22; second, National (Kincaid), 8:27,71; third, Apperson (Harding), 8:50.65.

Ten Mile Race for Light Cars—First, Chalmers-Detroit (Matson), 9:49.46; second, Chalmers-Detroit (Knipper), 9:49.84; third, Buick (Nelsa), 9:50.18. Also ran: White, gasoline; Fuller.

Ten Mile Free-for-All Handicap—First, Marmon (Stillman), 8:54.96; second, Harmon, (Harroun), 8:55; third, National (Aiken), 8:041. Also ran: Renault Frères, Rainier, Knox.
Two Mile Free-for-All—First, Fiat (Strag).

Two Mile Free-for-All—First, Fiat (Strang).
1:31.63; second, Benz (Oldfield), 1:37.18; third,
National (Aiken), 1:43.22. Also ran: Christie.
Two Hundred Mile Stock Chassis Race—First.

Two Hundred Mile Stock Chassis Race—First, Buick (Chevrolet), 2:46.48; second, Chalmer-Detroit (Dingley), 2:53.33; third, Chalmer-Detroit (Lorimer), 2:55.15. Also ran: Renault (Basic), Rainier (Marmon), Renault (Cliquoett), National (Aiken), National (Kincaid).

#### Rae Electric Vehicle Company Settles in Springfield, Vt.

The Rae Electric Vehicle Company have decided to locate in Springfield, Vt. The company have purchased 15 acres of land and will immediately begin the erection of two 200x50 foot buildings, which are expected to be ready for occupancy December 15. The officers of the company are H. K. Parkman, president; F. B. Rac. vice president; H. C. Welch, treasurer, and H. A. Bingham, secretary. Frank B. Rac, the inventor of the vehicle to be built, who formerly resided in Detroit, Mich., will have personal charge of the plant. The treasurer, H. C. Welch, is largely engaged in the shoe manufacturing. The first model to be turned out will be a runabout with double motor equipment, the motors being directly secured to the rear axle, with a guaranteed mileage of 90 on one charge of the batter-

#### New World's Speed Records.

According to cable reports from abroad, Auguste Hemery, driving a new Benz racer, made five new world's speed records on the Brooklands track in England on November 8, as follows:

Flying Start—One-half mile, 0:14.08s (=127.82)
m. p. h.); one kilometre, 0:17.761 (=125.94)
m. p. h.).

Standing Start—One-half mile, 0:25.566 (=70.406 m. p. h.); one kilometre, 0:31.326 (=71.406 m. p. h.); one mile, 0:41.268 (=87.233 p. h.).

**NUMBER 20** 

### The Elusive Five Hundred Dollar Car.

By A. C. Woodbury.

It is said that when R. E. Olds was doing his early automobile experimenting, nearly two decades ago, he had in mind the building of a car to weigh 500 pounds and sell for \$500. He found it impossible to construct a car, at least commercially, without considerably exceeding his specified weight, and he sold few if any cars in those days for less than \$650. Since then there have been many who have sought to build cars to sell for \$500 or less, and to the lay mind it seems that a simple car could easily be built at that figure. Let us see what the history of the \$500 car has been.

#### HISTORICAL RESUME.

Several \$500 cars were placed on the market in 1904 and 1905. Probably the leading ones were the Pope-Tribune and the Gale. The little one cylinder Pope-Tribune seems never to have achieved great success on the road, and the Hagerstown plant which was devoted to its manufacture was turned over to the construction of two and four cylinder cars of greater cost. The conclusion seems to be warranted that the car was inadequate. The Gale car was made by the Western Tool Works, Galesburg, III., and was built on the lines of the so-called standard American runabout of the day. It was seen little, if at all, in the East, and I can say nothing about its quality or success, but the company has since turned its attention to the making of larger cars, to its exclusion. In passing it may be noted that the price of this car with double tube tires was \$550.

In 1904 it was announced that the Ford Motor Company would soon bring out a four cylinder runabout to sell at a price from \$400 to \$500. The price of \$500, with single tube tires, was announced at the time of the exhibition held in New York by the unlicensed automobile manufacturers in January, 1905. In order to get double tube tires \$50 extra must be paid, as was the case with the Gale car as noted above. After some months it was found that nearly everyone required the double tube tires, and the price of the car was advanced to \$600 with double tube tires and perhaps some minor improvements. So this car passes out of the class under consideration.

The Brush runabout came on the market in the season of 1907. It was an honest attempt to reduce the automobile to about its simplest elements without excess weight or excess power, and to build well what there was of it. The price was \$500 with solid tires, for which the car was specially designed, and \$550 with pneumatic tires. It appears that pneumatic tires have been most called for, as the economy of solid tires seems to be very doubtful, and the 1910 announcements of the Brush Runabout Company make no mention of solid tires, but the price with pneumatic tires is reduced to just a little less than \$500.

The announcements of 1909 automobiles were marked by news of the entrance of three important firms of several years' standing in the industry into the \$500 class. Mr. Olds had at last placed on the market a \$500 car which was practically the same as the single cylinder Reo car for 1908, costing \$650, but I will not say that he has not changed his ideal as to weight from the 500 pounds of early days. So far as I know, this car will be continued for 1910 at the same price. The second new \$500 car was a smaller edition of the two cylinder Maxwell runabout, which had been on the market for several years. This was fitted with a smaller engine and smaller wheels than the regular Maxwell runabout, and was smaller in general, but was built along the same lines. The 1910 announcements of the Maxwell-Briscoe Motor Company indicate that this car is to be equipped with a magneto next year and the price is to be increased to \$550, while the larger two cylinder runabout is to be dropped. So, strictly speaking, this car also passes out of the \$500 class, but as the magneto might possibly be classed as extra equipment we will perhaps strain the point a little to keep it on our list. The Holsman Automobile Company, Chicago, Ill. also reduced the price of their high wheeled car with plain buggy body to \$500.

There have been several other cars placed on the market for \$500 or less. The Jewel was powered with a small single cylinder, two cycle motor, and sold for \$500, with a plain piano box body, and for \$600 with stanhope body. I have never seen this car and know nothing of its performance, but believe it was made in some numbers by the Jewel Motor Car Company, of Massillon, Ohio, who now make a comparatively expensive car with four cylinder, four cycle motor. The Orient buckboard was brought out about six or seven years ago, and then consisted of little more than the engine of a motorcycle mounted on four wheels. with a clutch, a small seat for two, and a tiller in place of a handle bar. The tread was less than 50 inches, so it was not at all suited to country roads, where there is often no smooth surface but two tracks or ruts for the wheels, 56 or 57 inches apart, and a rough surface or single track between, where the horses travel. In following seasons the buckboard was fitted with a two speed gear (no reverse), and finally with a friction transmission gear, and a two cylinder V motor-still air cooled and uncovered-at the rear was given as an option while the tread and wire wheels remained the same, and the price was increased to \$425 or more with the two cylinder engine. The factory at Waltham, Mass., where this car was made, is now in the hands of the Metz Company, who make a car in some respects similar to the latest buckboards, but with an opposed engine under a hood in front, larger wheels and a real runabout body. This car is sold in a knocked down condition for \$378. While this is considerably less than the price of our title, it is probable that when the labor or cost of assembling, etc., is counted up the result will not be far from \$500.

There have been other motor buggies built at prices from \$500 down, some of them not even having pivoted front axles, but a steering wheel connected by a vertical post and chains to the front axle in place of the thills. This construction does not work so badly as one might expect, but my single experience with a car of this class does not qualify me to properly judge others which may be more successful. There is probably nothing wrong with the principle of a buggy type car, but large wheels and solid tires will not drive a car without some assistance from the engine.

We have briefly described eight cars which have been on the market for \$500. (The buckboard and the Metz plan car are not included in that number.) Of these only three are now on the market for that price and one with magneto for \$550, while the manufacturers of four of the number seem to have found it more profitable to manufacture cars of considerably greater cost, the cheapest being \$825 or more. I believe this includes every car which has been sold on the American market for \$500 or less in quantities sufficient to be worth considering, unless it be one or two makes of motor buggies. What is the reason that there are not more? It surely is not because no one wishes to buy cars at that price-witness the quantities in which several of these have been sold. It must be that it is a much more difficult matter to design and build a really useful and satisfactory car at so low a price than would appear on the surface. That low priced cars can be built to the best advantage in large quantities only will be conceded by everyone, so it is harder for any new concern to get to the point where profits may be realized in the manufacture of moderate or low priced cars, while without large capital it might be impossible to push the sale of a very low priced car to the point where the quantity produced would insure a profit.

#### DEVIATION FROM STANDARD PRACTICE.

It will be noticed that each of the successful \$500 cars has in some way broken away more or less from the accepted practice in more expensive cars. In the Brush car a smaller engine is used than in any of the more pretentious American cars of the present day, and the whole car is made light in proportion. Also, the combination of spring suspension, distance rods and chain drive is probably cheaper to manufacture than the more standard constructions, and some instances of combination of functions in a single part are to be observed. In contrast to this note the four cylinder engine of the Ford runabout. It is perhaps not to be wondered at that the manufacturers of this car found it necessary, or at least expedient, to first reduce the agents' discount and then raise the price progressively. The Reo car is an example of simply reducing the cost of manufacturing in quantities, a car of the general type which was formerly popular at prices of from \$650 upward, but has now been rendered nearly obsolete by the demand for the smoother action and more power generally obtained by increasing the number of cylinders. It is nevertheless a type which has its advantages, and does not deserve to be discarded, because of its simplicity and directness. In the Holsman machine the economy comes in the air cooled engine of the simplest possible design for two four cycle cylinders, the substitution of two chains with only four sprockets, a jaw clutch and a type of belt drive, for the ordinary transmission, clutch and driving gears, and the buggy construction of the body at least of this simplest car must be cheaper than of most automobile runabouts. It may seem that the Maxwell is an exception to this rule of special design to reduce the cost, but at least the car is made smaller and lighter than any of the more expensive runabouts with resulting reduction in the cost, notably of the tires. It is also to be noted that the price has been raised above the \$500 figure.

#### THE TWO CYCLE CAR.

It is to be wondered at that the two cycle engine, which made possible the practical low cost motor boat, has been so little in evidence upon low cost automobiles. In its simple forms it would have the advantages, as compared with a four cycle engine of the same number of cylinders and

the same power, of lower manufacturing cost, owing to the absence of the valves and their actuating mechanism, more even torque, easier cooling, in spite of the general impression to the contrary. In the two cylinder form the cylinders may be vertical instead of opposed, and the system of mixing lubricating oil seems to be thoroughly practical and less expensive in first cost than any other method of engine lubrication. The item of more even torque alone is of great importance, for the "jerky" action of the single cylinder four cycle engine under some conditions was undoubtedly one of the chief reasons for its being so generally abandoned. It can also be conceived that the facility with which a two cycle engine may be reversed might make it unnecessary to provide a geared reverse if the ignition and engine control were arranged with that in view.

The reasons which have prevented the more common adoption of the two cycle engine for this service seem to be somewhat as follows: The engine which first made the gasoline automobile possible was the light, high speed Daimler type. The two cycle marine engine was not at all suitable because of its low speed and heavy, clumsy construction. It is little if any more difficult to make a two cycle engine of light design than to make a four cycle engine so, but when it came to increasing the speed more difficulties were encountered, first with the cylinder ports, which had to be more ample than the marine engine makers of that day ever dreamed of, then with the crank case inlet. The "mixing valve" or "generator valve," usually consisting simply of a brass check valve provided with a small hole in its seat for the entrance of gasoline when the valve was opened by suction from the crank case with a needle valve to regulate the amount of gasoline fed, proved entirely inadequate. The three port type of engine, probably the simplest and cheapest practical form of gasoline engine to manufacture, can be so designed as to be quite suitable for comparatively high speed, but is hard to supply with a suitable mixture for variable speed unless the engine has four or more cylinders so as to make the suction on the carburetor more nearly constant. Any form of mechanically operated inlet valve, even discs on the crank shaft, is bound to add materially to the complication of the two cycle engine, and thus to discount one of its main advantages over the four cycle engine. It seems to me that the real solution lies in the direction of an automatic crank case inlet valve, although many of these are either so clumsy as to be ill suited for high speed or so delicate as to be liable to derangement, and perhaps expensive to produce. However, there are some in use which are both rugged and responsive. Also, the combination of an automatic inlet valve, to allow the engine to draw on the carburetor while the piston is going up, with a third port, to allow the crank case to fill, even if the valve is sluggish, has been used and is thoroughly practical. Another reason for the slowness of both manufacturers and purchasers to adopt the two cycle engine may be called either conservatism or prejudice. The four cycle engine was developed to a usable state for automobiles first, and there have undoubtedly been some attempts to adapt two cycle engines which did not meet with great success. Consequently many purchasers are doubtful about the wisdom of buying "two cycle experiments," and most manufacturers have been too busy making cars which they knew they could sell to spend much thought or money on what they may admit to themselves might have advantages.

#### SIMPLE BODY CONSTRUCTION.

One more simplification which would seem quite practical for a cheap car is the building of the chassis frame in such a form that the mere addition of the floor boards, dash and one or two seats would complete the body. The "democrat wagon" style of body would seem well suited for this purpose.

I believe that in a few years the \$500 car will be an immense factor in the automobile business. It is a branch of the industry which has barely been touched upon as yet, and the man who will do successful work along this line of reducing the automobile to its simplest form so as to make it available to the thousand dollars a year man may not only obtain financial reward but may become a real benefactor of his fellow men as well.

#### A Remedy for Fierce Cone Clutches.

There are few things more annoying to the average motorist than a harsh or grabbing clutch, especially in driving through heavy traffic in the city, where a great many stops have to be made.

Although some manufacturers seem to have solved the problem satisfactorily, the writer has, during several years' experience as a repair man, found a large number of the leather faced cone variety which gave trouble right from the beginning, and no amount of spring adjustment or soaking in different kinds of oil would remedy the trouble.

I recently tried inserting small strips of ordinary sheet tin or copper under the leather, and it has remedied the trouble in every case. The strips of metal should be cut about three-eighths of an inch wide and half an inch longer than the width of the clutch. They should be inserted under the leather and the ends bent over the metal part of the clutch to hold them in place. About four strips, spaced equal distances apart, are usually sufficient to give good results.—G. A. Marquards.

The Paris publication L'Auto is organizing an endurance contest for small cars, which is to be run December 5-19. Already twenty-six entries have been received, practically all of them from French manufacturers.

### Calculation of Chassis Springs—III.

#### By David Landau and Asher Golden.

DETERMINATION OF THE NUMBER OF LEAVES AND THEIR THICKNESS.

After knowing the flexibility required in any given case the next important step in the design of a spring is to find the number of leaves and their thickness.

For this purpose, it is convenient to regard the spring as being made up of two cantilevers, each taking half the load. The advisability of treating the spring in this manner will appear from the great number of actual cases in which the springs are eccentrated. Here the spring consists of two "halves" of unequal length. If the load is taken to be the same at each end, then the flexibility of each "half" of the spring must be the same in order that the deflection of both ends may be the same under the same loads. In practically all cases, however, the loads at each end are not the same; it is then necessary to take each "half" of different flexibilities in order that, as before, the deflection of both ends may be the same under the different loads.

Of course, an eccentrated spring may be treated as an eccentrically loaded beam, but we believe it is far simpler to treat it as being made up of cantilevers, whether it is eccentrated or not.

It is evident from what has just been said that when we speak of the flexibility of a spring we mean the "total flexibility," which is made up of two partial flexibilities, and it is necessary to find these partial flexibilities to get the total. It will suffice for all practical cases, however, whether the spring is eccentrated or not, to assume a single flexibility for the whole spring, then make the leaves slightly thinner on the side sustaining the smaller load.

The maximum deflection of a cantilever of uniform section with a single concentrated load at the free end is

If the cantilever consists of n leaves all of the same thickness the deflection is

$$d = K \frac{P l^3}{3 n E I} \dots (16)$$

where K varies between 1.2 and 1.5. If the n leaves have the same width but different thicknesses and the moments of inertia of these leaves are I<sub>1</sub>, I<sub>2</sub>,.....I<sub>n</sub>, then

If in equation (17) we take the total load on the spring to be 100 pounds, that is, 50 pounds on each end, we have the deflection of the spring per 100 pounds. This is defined as the flexibility and is denoted by the letter f. Equation (17) may then be written

. The moments of elasticity, E I, may be easily found for plates of different widths and thicknesses and arranged for convenience in a table. It is then only necessary to know the flexibility required for any given case, substitute it for f in the following equation and pick out such leaves,

Substituting these numbers in equation (19), we have

$$\Sigma$$
 (E I) = 1.3  $\frac{50 \times 20^8}{3 \times .25}$ 

== 603000

We will assume that the spring is to be made of the steel having the modulus 28,-

the sum of whose moments of elasticity shall be equal to  $\Sigma$  (E I).

$$\Sigma (E I) = K \frac{50 \, I^3}{3 \, f} \dots (rg)$$

We have prepared tables II and III of moments of elasticity for leaves of widths and thicknesses usually employed for springs and for moduli of elasticity of 24,000,000 and 28,000,000, representing, respectively, an ordinary carbon spring steel and a high grade alloy steel.

As an example in the application of the above tables and equation (19), let it be required to select the leaves for a spring having the following dimensions and characteristics:

	Inches.
Length under load	. 40
Half length	. 20
Width of leaves	. 2
Flexibility	25

000,000. Looking, therefore, in the first table, under the head 2 inches, we pick out such numbers whose sum will approximate 693,000. We thus find

#### FORM OF THE LEAVES.

We do not think we can add much to what has already been written on this subject. There are, however, a few points about which little, if anything, has been said.

The bending moment at any point of a cantilever is directly proportional to the distance of the point from the free end. If  $M_h$  is the bending moment and Z the

section modulus at any point, then the fibre stress is

$$S = \frac{M_h}{Z} ,$$

from which we see that for a cantilever of uniform section the fibre stress is proportional to the bending moment, and therefore the distance from the free end. We can get a uniform fibre stress, that is, uniform strength, at every section by making the section the least at the free end and gradually increasing it as we go toward the point of maximum moment, that is, the spring seat. With other parts this is easily accomplished by means of webs or other forms of compression members. method cannot be practically applied to a spring; but, owing to the fact that the spring is built up of layers, it is only necessary to step these to gain the desired end.

It must be remarked that every separate leaf, as well as the entire spring itself, is also a cantilever subject to the same laws, and should be constructed so as to be of uniform strength. This is done by making the leaves thickest at the spring seat and gradually thinning down toward the spring eye. The thickness of the leaf at the spring seat is that selected from the tables of moments of elasticity. The thickness of the leaf at any other point may be found as fol-

The fibre stress at any section of the leaf is

$$S = \frac{M_b}{Z} = \frac{M_b}{\frac{I}{v}}$$

where y is the distance from the neutral axis to the outermost fibre. Since for uniform strength S is to be constant, the ratio

1/y must be proportional to Mb. Now, since  $1/y = \frac{b t^2}{6}$ , we have

$$M_b = \frac{S_b \ell^2}{6},$$

from which it is seen that  $b t^2$  must be proportional to Mb.

The bending moment at any point of a cantilever distant x from the free end is Px, where P is the load. We therefore

$$P x = \frac{S b t^2}{6}$$

or, since the width of the leaf is constant, the thickness of the leaf at the point x is

$$t = \sqrt{\frac{6 P x}{S b}}....(20)$$

There are many instances where the leaves are not made of uniform strength. In such cases the material is not used to

the best advantage. While it is true that some strength is added to the spring if the leaves are not thinned down, the added strength is gained at the expense of too much material.

MAXIMUM DEFLECTIONS TO WHICH SPRINGS
MAY BE SUBJECTED WITHOUT TAKING
A PERMANENT SET.

In the early part of this article we quoted one manufacturer as saying that he does not know the elastic limit or the tensile strength of the material he uses. We are told, moreover, that these characteristics do not necessarily give assurance against settling or breakage. This is erroneous. Knowing the elastic limit of the material certainly does enable us to determine under what conditions the deflections of a spring cease to be proportional to the load. If a beam or cantilever be subjected to

bending the skin in tensions will be stretched a certain amount, which we call the elastic elongation. This elongation, e, is expressed by the relation

$$e = \frac{a}{\kappa}$$

where a is the elastic limit of the material and E is the modulus of elasticity. For spring steels, the amount of stretching is found to be between .003 and .907 of the initial length.

The maximum safe deflection of a cantilever consisting of a spring leaf of thickness t is

where s is the developed length of the master leaf; from equation (21) we see that the maximum deflection is proportional to the elastic elongation. By maximum safe de-

flection we mean the distance through which the leaf or spring will move without taking a permanent set. After we have passed this point the spring will settle; hence the assurance that the elastic limit gives no indication of the susceptibility of the spring to settle or break is not borne out.

Once we have determined the elastic limit of our material we can employ equation (21) to construct tables showing the maximum safe deflections of spring leaves of different lengths and thicknesses.

As an example of the application of equation (21) we will take a spring having a developed length of, say, 36 inches with a master leaf .284 inch thick. Assuming that a has the value .004, we have by substitution:

$$D' = \frac{36^2 \times .004}{4 \times .284} = 4.28$$
 inches;

that is, if this spring is deflected more than 4.28 inches it will take a permanent set. In the manner here indicated we have constructed Tables IV, V and VI for different values of  $\alpha$ . It is clear that in any case the engineer will limit his deflections so that

they may be well within the values given in the tables.

(To be continued.)

# The Location and Standardizing of Cylinder Leaks.

By R. M. A. inders averaged evenly, so that such a

pressure was arrived at that showed but

slight variation on the gauge. Too low a

pressure must be avoided, since the rate

of filling the cylinder volume is a function

of the pressure, and with a large number

of cylinders much time would be consumed.

sents the orifice C, so that we may vary

this orifice to suit individual standards and

then remove the hand wheel to avoid tam-

pering. To the right of B is the factory

pressure and shut-off globe valve A; to

the left of B the low pressure gauge is con-

nected with a fitting allowing flexible con-

nections to be made to the cylinders. This

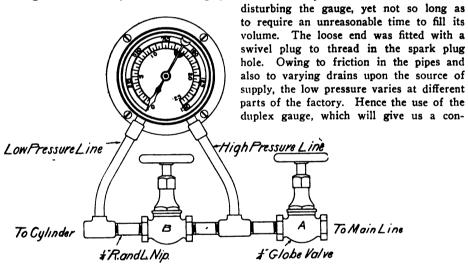

flexible connection was of suitable length

to reach all cylinders on a motor without

In the sketch the globe valve B repre-

We will deal with the leakage of compression in cylinders, and the determination of such leakage at valves, packing rings, etc., without involving the relation of piston stroke volume to clearance volume. To so relate a set of cylinders that they may be uniform in compression leaks is quite difficult without some recourse to accurate measurement which will tell when a cylinder is standard or not. Trying the cylinders of an engine by cranking each separately for its compression and then "swapping" the "weak" one of one engine for the "strong" one of another motor is depending too largely upon the personal equation.

The following principle and apparatus have given satisfactory results: Roughly

speaking, air flowing through an orifice C at one end of a short pipe will be greater in pressure in proportion as the second orifice Y, at the other end of the pipe, restricts the passage of this air. With the inlet C a constant, and Y a variable, the pressure will vary in the connecting pipe—assuming the volume of air behind C constant in pressure and infinite in volume—in proportion to the volume escaping at Y. We can easily fix these constants for our use and read the variable Y with a low pressure gauge.

Applying this to the cylinder, the sum of its leaks will represent Y, and when these are equal to C the gauge will show no pressure, etc.; Y in this case being small requires little pressure to give a sensitive appreciation of the presence of leaks. From 15 to 20 pounds has been found convenient. To obtain this, cylinders of a finished car were averaged by changing the opening in orifice C. To the hand crank these cyl-

stant standard. The high pressure calibrations were 0-150 pounds, and the low 0-125 pounds. Then with the main line at 90 pounds, and the reduced line taken as 15 pounds, the arrows are parallel. Any increase or decrease in leakage will affect but one arrow, and this variation is easily noted.

With the above apparatus one man can easily keep pace with the rest of the work on the motors, care being taken to have the amount of oil equal for all pistons, as well as to have the pistons at the same part of the stroke in each case, i. e., the top centre. For bench testing each piston, previous to being put into the cylinder, is dipped in a pan of oil to a given depth to insure a uniform oil packing around the rings.

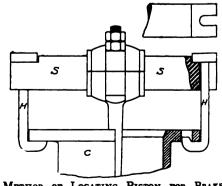

The second sketch is intended to convey a suggestion for accomplishing rapid change and insure constant position of the piston in bench testing. S is a shaft slotted

at both ends to receive hook clamps H H. This shaft is equal to the diameter of the crank pin, less one-thirty-second inch, and is hardened to avoid nicking, and thus scratching the bearing when drawn through. The hook clamps H H are of such length as to give the piston the same position as the stop centre. The hooked ends are relieved where they engage cylinder C, so that they may be drawn out of or put in the end slots of the shaft. It is apparent that the axis of shaft S is parallel to the diagonal of the bolt holes of the cylinder flange. We depend upon the rings to hold the compression, so the piston and its rings are inserted in their customary way, then the piston is turned through 45 degrees. Owing to their friction on cylinder walls the rings maintain their original location.

In the case of T and L head cylinders, by inverting the cylinder, as shown in the sketch, the valve ports are easily inspected. Soap and water are cheap, and if applied to the valves and the edge of the piston, while air pressure is turned on, will plainly show any excessive leakage.

The following experiments are of interest:

- (1) Determination of the curve showing the effect of "running in" the piston rings, the valves being ground before each test, and a given quantity of oil being injected into each cylinder to insure uniform packing.
- (2) In combination with such an average curve a series of tests (a) with different quantities of the same oil, and (b) with constant quantities of different oils, to determine the effect upon the valves when not ground after the run.
- (3) On model cars at intervals of a few days' run to determine the life of compression and frequency of grinding valves.
- (4) To determine whether a cylinder that has held good compression will continue to do so or not, and vice versa.

METHOD OF LOCATING PISTON FOR BRAKE
TEST.

#### Ignition Terminology.

Recently the question was put to us, "What is the difference between a high tension and a low tension magneto?" and we were at a loss to give a concise answer, for the reason that there is one class of magnetos which is classed by some as a high tension and by others as a low tension device. The type referred to is, of course, that in which a low tension current is generated in the armature, which is "stepped up" by means of an outside coil and distributed to the different cylinders by means of a high tension distributor combined with the magneto. The manufacturers of this type of magneto generally refer to it as a high tension magneto, and the manufacturers of the other type in which a current of sufficient pressure to jump the spark plug gap is generated directly in the armature, in order to distinguish them from the first mentioned type often refer to them as true high tension or direct high tension magnetos. This terminology is evidently somewhat clumsy

and unsatisfactory. We would suggest the adoption of the following terms, which are herewith submitted to ignition specialists for criticism or adoption:

High tension magneto—a magneto generating in its armature a current of sufficient tension to jump the gap of an ordinary ignition spark plug.

Low tension magneto—a magneto generating in its armature a current of low tension adapted for use with a contact spark ignition system.

Low-high etnsion magneto—a magneto generating in its armature a low tension current and provided with a separate induction coil for raising the tension to that used in high tension ignition systems.

The novel ignition generator recently brought out in Springfield, Mass., which was described in one of our late issues, also calls for a new addition to scientific nomenclature. It is evidently a magneto generator, since it generates current mechanically by means of a magnetic field due to permanent magnets. In order to distinguish it from the revolving armature type of magnetos it might be well to refer to it as a drop armature type.

#### The Left Hand Control.

Quite a number of designers have always maintained that the left side of the car was the proper position for the driver. Although numerous early experimental cars were built with the control on this side, only a few makers have ever manufactured cars with left hand control in any considerable numbers. Last season, however, one of the leading makers adopted this position for the driver, and among the announcements of the past few months there is considerable evidence of a revival of interest in this style of construction.

Among the objections urged against the left hand placing of the driver are the alleged difficulty of judging the position of the curb when approaching it with the right hand side of the car, and of operating the hand levers. If these latter are placed upon the left side of the driver they must be operated by the hand which is the less skillful in the majority of persons. If they are placed in the centre of the vehicle there is danger of the operator's arm interfering with the other front seat passenger. It should be remembered, however, that the movements required in hand lever operation are comparatively simple, and a sufficient degree of skill is readily acquired.

As to the merit of the other objection,

we have talked with quite a number of drivers, and their opinion seems divided, some claiming that a car can be driven close to either curb with equal facility no matter which side the driver sits on, and others claiming quite the reverse.

A similar difference of opinion exists with regard to the advantages of the two positions when meeting another vehicle.

Probably the recent enforcement of the ordinances which require a vehicle to stop with its right hand side toward the curb has been one of the reasons for the renewed interest in left hand control. For as cars are made at the present time it is usually unhandy to enter or to leave the front seat from the driving side. This unhandiness could, of course, be largely done away with by the use of sliding or tilting steering wheels, but at the present time there seems to be no evidence that they will be adopted.

# The Atlanta Show from the Exhib- - itors' Standpoint.

While from the standpoint of gate receipts the late Atlanta Show perhaps did not come up to expectations, the majority of exhibitors considered it a success either from the standpoint of immediate business or from that of its advertising value.

It was the opinion of nearly everybody who had given the slightest thought to the matter that the comparatively small attendance was entirely due to the races, which certainly drew enormous crowds. Every day of the meet both the grand stand and the bleachers were at least three-quarters full, to say nothing of the large number of cars parked inside of the track. When it is stated that the grand stands and bleachers are of more than twice the size of those at the ordinary mile tracks it is readily realized what this means.

While this state of things was decidedly bad from the viewpoint of the show management, yet it may not have been an unmixed evil. There is little doubt that the exceedingly fine program of races at the track offered far greater attractions to persons only casually interested in automobiles and those who were simply in quest of amusement. On the other hand, those who came from some distance, as many undoubtedly did, to see the races would be almost certain to visit the show as well, and, of course, many of this class are likely to be either immediate or prospective buyers. It is probable, too, that the fact that the attendance was small and made up to a great extent of enthusiasts gave the salesmen and demonstrators a much better opportunity to give proper attention to prospectives. In a talk with the vice president of a leading company, a pioneer in the industry, this gentleman stated that he had seen more real automobile enthusiasm in Atlanta than he had seen in any other city in a long time. Going into particulars, he said that his company had sold five of their larger cars during the show, and that from what he had seen of the situation in the South the market there was about the same as it was in the North and East five years ago, and that the prospects of development were fully as promising. A local agent for a well known make of car stated that he had sold every car which he had on exhibition, as well as two others which had been shipped for the show, but which, owing to lack of space, he had kept at his showrooms. The only firm exhibiting foreign cars at the show said that they had sold two of their cars, and, considering everything, were well pleased with the results.

That business was not confined to any one class was evidenced by the fact that the exhibitors of the four lowest priced cars in the show were most enthusiastic in giving expression to their satisfaction.

The representatives of almost all of the motorcycle manufacturers, on the other hand, expressed themselves as being disssatisfied with the results of the show. They ascribed the lack of good results to two causes. The first, of course, was the counter attraction of the races, and the second was the fact that the location of the motorcycle exhibits was somewhat out of the way, and very little publicity was given by the local papers to this portion of the exhibit. That there was some truth in this would seem to be indicated by the fact that various parts and accessories exhibitors who were located in this portion of the building were not as well satisfied as others who had different locations. On the other hand, the representative of a well known car which was located in this section stated that his prospective business was very good, and that he had demonstrations booked into the middle of the following week, many of them being with people who had stopped over in town for that purpose. While none of the parts manufacturers expressed themselves as dissatisfied with the results of the show, yet they were not nearly so well pleased as the exhibitors of cars. This was only to be expected, as it is almost impossible to judge of the results of a show in this line, comparatively little business being done with the consumer direct, the business mostly passing through the agents of cars, and through garage and repair shop keepers. However, even in this line there were many who expressed their satisfaction in unmistakable terms.

The consensus of opinion seemed to be that in future, if the Atlanta Show should be repeated as a national show, it would be better to have no counter attraction in the way of races. Just what effect the show has had it will, of course, be possible to judge much better in the course of the next selling season, and the fate of this fourth national show will undoubtedly depend upon the development of the Southern market during the coming year.

#### New Jersey Vehicle Lighting Law Not Enforced.

Our attention has been called to the fact that the New Jersey vehicle lighting law, passed some months ago, is by no means generally enforced, numerous teamsters still continuing to drive after dark without displaying lights as required. The passage of the law was followed by considerable rejoicing among the motorists of the State, at whose instigation the bill was introduced, but if the benefits of the law are not to be lost it seems that immediate steps are necessary to urge its strict enforcement. Such a law on the statute books without being enforced is much worse than no law at all. as it gives road users a false sense of security in this respect. Motorists are interested most in the matter, as unlighted slow going vehicles are a great menace to the faster moving vehicles. New Jersey has a strong motorists' organization, which by inquiry among its members could easily obtain reliable information as to the extent the law is being violated, and a complaint lodged by the club with the authorities, if deemed necessary, would undoubtedly result in a stricter enforcement of the law.

#### Obituary.

E. Shriver Reese, who had been prominent in the affairs of the Cleveland A. C., died at that city on November 5, after an illness of two months. Mr. Reese was an insurance man and a native of Baltimore.

Robert H. Dowie, manager of the Seattle branch of the Fisk Rubber Company, at 910 East Pike street, died November 6 at Minor Hospital, where he had gone to be operated upon for cancer. Mr. Dowie was twenty-nine years old and one of the best known tire men in the Northwest.

#### Motor Buggies at the Atlanta Show, By C. E. D.

The display of motor buggies was, to say the least, disappointing. The South has been looked upon by many as the proper field for the large wheeled motor vehicle and it was expected that a goodly number of them would be seen there. Certain it is that the large wheels roll over the bad roads easier than small ones, and equally certain that the creeks and fords of the South often demand high wheels to carry the mechanism out of reach of the water. But another fact equally certain seems to not have been reckoned with. The public does not often do things in the most scientific manner nor does it always do the right thing. The pioneer automobile makers reasoned that the motor vehicle would be a development of the horse buggy, and found to their disappointment that the bicycle was regarded by the public as the father of the new industry, and such features as light, small steel wheels, bicycle chains and toy engines were among the first to find favor. The South is a new field going through much the same educative development, and if the show at Atlanta is any criterion they are making a similar although not the same mistake.

#### ATLANTA AUTO MAD.

Growing rapidly and making money iast. they have taken up the motor vehicle with a rush and an enthusiasm seldom or never seen equaled before. The newspapers in particular have been a unit in getting the new vehicle and the matter of good roads before the public. For this altruism they deserve a credit they will probably not get. In short, Atlanta is auto wild. In a city of 150,000 to 200,000 people are to be found about fifty sales agencies, each handling from one to four or five different makes of cars, and it is certain that the show will be the cause of several, if not many, more being established. Practically all of these handle the conventional type of cars, and the motor buggy type seems to be almost if not quite neglected. Naturally the agent prefers to sell to the wealthier class, and so selects a high grade article; but it is a very serious question if this trade will not soon be supplied and this business badly crippled by exhaustion of the supply of buvers.

#### HOPES FOR GOOD ROADS.

On every side is heard the argument that "good roads are at hand," but other communities have found that it takes years to make roads, and while for pleasure purposes a few good roads will serve, the demands of daily life require roads to be traversed that are not good and will not be for years to come. All these facts point to the motor buggy as the proper solution of the motor vehicle problem now being considered by the South. The roads need it, the people need it, and the dealers and makers of conventional cars will find it a step forward from the horse vehicle which many, not yet

561

ready to buy conventional cars, could be induced to take, with the result that the sellers of conventional cars would profit in the future. The man who gets a taste of automobiling behind the lever of the light motor buggy is not likely to be happy till he twirls the wheel of the larger and more expensive car.

Today he sticks to the horse because he fears the complicated machinery, which, being a mystery, is fearful to him. He fears the tire troubles, which he does not enjoy overcoming himself. He fears the heavy weight, high maintenance cost and large fuel and oil bills. So the old horse and buggy will for him plod deliberately along for some years to come. But toward the motor buggy he feels differently. It looks familiar. He knows the life and strength of hickory spokes, long and limber enough to act as springs and largely save the vehicle by their resilience. He has seen hard tires in use for years and has no fears of them. He will consider a most simple mechanism if he can understand it and be much easier induced to buy than if brought a large structure which he does not understand. Once let him enter the ranks of the power propelled vehicle users and he is not likely to go back. He may, as do many doctors in some of the Northern cities, keep his touring car for pleasure and drive a solid tire rig for business, and even keep horses as a luxury, but he will not likely drop out of the ranks.

As for the buggies at the show, there were none. Makers who make and have heretofore shown them were there showing pneumatic tired rigs, but none of the buggy type with solid tires were to be seen. Whether they recognized the present as the time to sell the more expensive job, and so left the buggy behind, or whether they feel that their product is not wanted in or is not suited to the South, I do not know.

On the outside, two of the solid tire type were to be seen—one in the tent of the White Star Company, an Atlanta concern, who also exhibited conventional autos, and the other the Duryea Buggyaut, made at Reading, Pa.

The White Star motor buggy is a large, roomy affair, well built, and fitted with a 20 horse power, double opposed motor under the seat and planetary transmission, with Morse chain to the countershaft. Side chains from this carry the power to the wheels. Band brakes and magneto and battery form part of the fitting. Running boards and guards protect from mud perfectly. The impression is that of a solidly, even heavily built vehicle which should give good service. No demonstrations were given, and the selling efforts seemed to be confined to the conventional type autos also exhibited.

The Duryea Buggyaut has been described in these columns in the past. It is of very simple design, employing a two cycle engine with two cylinders nearly horizontal for better cooling and oiling. These cylinders are provided with copper spines which carry off the heat. The extended engine shaft ends carry rollers which frictionally engage rings carried by the rear wheels. These rollers and rings give two speeds forward and reverse, with all drives direct.

In the immediate vicinity of Atlanta, in Fulton County, there are several hundred miles of good or fairly good roads, and over these it is possible to travel at a good pace, but these are the exception rather than the rule. Georgia roads are being improved rapidly. The convicts are being put to work on the roads instead of being hired out to compete with honest labor in manufacturing or work of a limited amount. Their labor is being intelligently directed, with the result that some of the roads being built are models of engineering and worthy of imitation by the North. The expressions of the many visitors from all over the State, however, show that there is an abundance of sand in many parts, much mud and many obstructions, such as rocks and stumps. For such a condition the motor buggy is almost a necessity, and in spite of the failures of some of the cheaper and less well designed ones there is a big future for this type.

#### The Tent Shows.

Space at the main show was in considerable demand; in fact, quite a number of would be exhibitors who waited till the last moment were unable to obtain it. The White Star Automobile Company, of Atlanta, however, had secured considerable space, but seeing that they would crowd out visiting exhibitors they gave up the space and after renting a large plot of ground on Gillman street, within a stone's throw of the auditorium, put up a tent and opened a show of their own. They also took in one other belated exhibitor.

The Georgia Garage Company, on Edgewood avenue, put up a tent on a vacant lot adjacent to their quarters to accommodate any possible overflow caused by the visitors. In this tent were exhibits of the Gardner Engine Starter Company and of the Fellwock Auto Manufacturing Company. The Gardner Engine Starter Company showed a simple device for starting up small cars without cranking. A large flat spring is interposed between the two halves of the propeller shaft which is divided for the purpose. These two halves are ordinarily locked together by means of a dog clutch. When it is desired to start the motor, the high speed is thrown in and a special pedal is depressed. This latter disconnects the two halves of the dog clutch. The spring therefore acts and turns over the motor. As soon as the motor takes up its cycle the high speed is thrown out of action, the reverse is then thrown in. This latter action causes the motor to rewind the spring. As soon as the spring is rewound the machine will, of course, start to back. The pedal is then released and the two halves of the propeller shaft are again connected. The concern also exhibits a truss for strengthening

weakened rear axles, which is simple and easily applied.

The Fellwock Auto Manufacturing Company, Evansville, Ind., exhibited a line of metal rumble and surrey seats, which could be readily fitted to various runabouts not so fitted by the manufacturers. Among these are the Maxwell and Brush. They are made of metal and neatly upholstered. In addition to this line they also showed a line of wind shields with both brass and mahogany trimmings.

The White Star Automobile Company, of Atlanta, Ga., exhibited three machines with touring car bodies, one without a top and the other two with. This machine is equipped with a four cylinder motor having the cylinders cast separately, the exhaust valves in the heads and operated by rocker arms, and the inlet valves at the side and operated by push rods from underneath. The dimensions are 41/4x5 inches. Magneto ignition with Remy magneto is employed. The clutch is of the leather faced cone type. The transmission is of the three speed selective type with rocking lever and stubs. The wheel base is 110 inches and the tires are 32x31/2 inches. In addition to this they also have a high wheel solid tire buggy. This has 42 inch wheels and a wheel base of about 80 inches. The motor is a double opposed air cooled one, located under the body and driving the rear wheels through a countershaft by double side chains. This is accomplished by driving dogs on the rear axles which leave the wheels themselves so that they can be freely removed for greasing, as can be done with an ordinary buggy.

The Rohrbacher Automatic Air Pump Company, Blaine, Wash., showed their automatic air pump. This is a pump designed to be driven off of the flywheel by a friction pulley, being put into and out of action by a lever conveniently located. The pump is arranged so that there is a four to one reduction between it and the friction pulley, this reducing gear running in an oil tight casing.

Kelly in Control of Oscar Lear Company.

E. S. Kelly, of Springfield, Ohio, has secured control of the Oscar Lear Automobile Company of that city. An attempt was made by the General Motors Company to get control of this business, and it seems that they bought up a considerable proportion of the stock of the company, but last week Mr. Kelly got control of additional stock and is now in charge of the company's affairs. It is announced that the receivership will be lifted at once, and a complete reorganization carried through. The capital stock will be increased from \$200,-000 to \$500,000. The manufacture of pleasure cars will be discontinued, and the firm will confine itself to the manufacture of the air cooled Frayer-Miller trucks described in our issue of October 13, of which it is planned to turn out 400 during the coming year.

### DESCRIPTIONS OF NEW VEHICLES AND PARTS.

#### The New Brush Models.

During the past year the Brush Runabout Company, of Detroit, Mich., have followed their usual policy of carefully developing and testing out such changes as their experience leads them to believe desirable. As a result the models which they have just announced, while similar to this season's cars in general design, show a number of improvements.

Possible the most noteworthy of these is the balanced single cylinder motor. While the bore is 4 inches, as in former models, the stroke has been lengthened to 5 inches. This half inch increase in stroke considerably increases the pulling power of the motor, and probably gives greater maximum power. Possibly its less frequent and more powerful impulses might cause the car to vibrate unpleasantly if it were not for the unique balancing device which is used. A single cylinder motor causes a car to vibrate in two ways: First, by the up and down movement of its pistons. Second, by the reaction from its explosions,

To overcome this tendency to vibrate the Brush Company have added a counterweight on a revolving shaft just to the rear of the plane of revolution of the crank pin. A 6 inch gear is attached to the crank shaft, and the counterweight is placed inside the rim of a gear of equal diameter. Hence it revolves at the same speed as the crank shaft, but in the opposite direction. This movement causes it to balance practically all of the inertia of the reciprocating parts. At the same time, owing to its position with relation to the crank shaft axis, it makes the torque reaction practically uniform for the usual speeds of running. The counterweight shaft is mounted on a single New

Departure ball bearing. The gears are spirals, with a tooth angle of 15 degrees. The usual counterweights attached to the crank webs are, of course, employed. The writer intends to explain this method of balancing more in detail in another article.

The crank shaft is 13% inches in diameter, The connecting rod is an I section forging, are lubricated by gravity feed, which flows into pockets cast in the crank case, which lead to suitable oil holes. These pockets also catch some of the splashing oil and form an additional protection against running dry. Great care has been taken to make the motor oil tight. The screwed-in air cooled head, which has been character-

BRUSH MODEL D28.

with a hinged bearing at the crank end. The crank case is of cast aluminum, the general shape being globular. The rear bearing support is cast integral, but the front bearing and cam housing are carried on an attached plate. The valves are in front, both mechanically operated. They have a clear diameter of 15% inches. The counterweight is inserted, and the connecting rod bearing may be adjusted through a conveniently placed hand hole. The cylinders are lubricated by splash. Other parts

istic of the Brush since the beginning, has been retained.

Cooling is by water, using a Mercedes type radiator, with thermo-siphon circulation. The flywheel is 18 inches in diameter, and is slightly heavier than in former models.

Connection with the change gear is made through a shaft with two universal joints. These joints are fully enclosed. The change gear is practically the same as that used in this season's model. It is a two speed and reverse planetary of the internal gear type. The low speed and reverse clutches are now of the multiple disc type. They are bronze and cast iron, and differ from those formerly employed only by the increase in the number of plates, which doubles the wearing surface. The high speed clutch is also of the multiple disc type. Hardened steel and bronze are used to obtain a somewhat more compact clutch than would be possible with cast iron plates.

In the new transmission the operating levers for the low and reverse gears are entirely enclosed. Every precaution is taken against leakage, permitting the use of light oil.

A fifteen tooth bevel pinion on the change gear shaft transmits to a twenty-four tooth gear on the countershaft. Sixteen tooth sprockets on the ends of the countershaft are connected by side chains to the fifty tooth sprockets on the rear wheels.

The same axle construction is used as in former models, the body of the axles

BRUSH 1910 ROADSTER, MODEL D26, WITH PRESIDENT FRANK BRISCOE AT THE WHEEL.

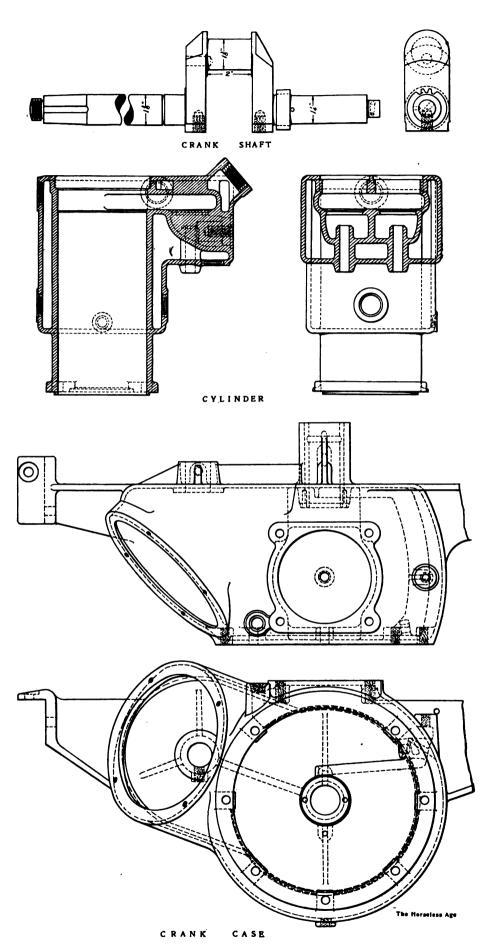

being of oil treated selected wood, while the wheels are mounted on suitable attached metal ends. The spring suspension remains as formerly. It consists of four helical springs set well out toward the wheels, whose vibration is damped by shock absorbers which serve as radius rods. A neat detail improvement in the suspension consists in a metal grease retainer over the ball end of the rod which connects the spring to the axle. The sockets for these balls are now lined with fibre. Oil treated wood is also used for the frame. The small parts of the running gear are mostly made from pressed steel, this material now being used in many places where castings and forgings were formerly employed.

Steering is by the well known Brush internal and spur gear combination. This is unchanged, except for slight alterations in the cases made necessary by the increased wheel base. A single hand lever controls the speeds, selectively, and a single pedal releases the clutch and applies the brakes. The brakes are of the expanding type and act on the wheel sprocket drums. Artillery wheels fitted with 28x3 inch pneumatic tires are used. It has been found that for this light car the pneumatic tires are very economical. The wheel base has been lengthened 6 inches, making it 80 inches. This increase in length allows more rakish body lines. The standard tread is 56 inches, but a 60 inch tread is furnished for the Southern trade.

As this car was designed to suit the needs of a wide variety of people, both for business and pleasure uses, several styles of bodies are fitted to this standard chassis. The regular body has a flat rear deck. A space for carrying tools is left under the seat. If slightly more carrying space is needed, the body known as D22 may be furnished. This has a large tool box at the rear, which may be used as an emergency seat. If a space is needed for larger articles the type D24 body may be used, which has a large carrying space covering the entire rear deck. This compartment is made tight by a removable steel cover. Model D28 is provided with a single rumble seat on the tool box for those who wish to handle a third passenger.

To meet the demand for a more speedy and racy looking car the Model D26 was produced. This car has a higher gear and is regularly equipped with a magneto, provisions for which are made on the other models. It has been found that there is a considerable class of users of small cars who wish to be more completely protected from the weather than is possible with an open body. For these the Model D coupé is provided. It has inside control and is finely finished.

Panhard & Levassor have decided to take up the manufacture of Knight slide valve engines in France. Mr. Knight has just returned from Paris after concluding arrangements to this end.

Motor Parts.

### The K-R-I-T Models.

The Krit Motor Car Company, of Detroit, announce as their first productions a line of runabout and roadster models obtained by combining various bodies with a standard chassis. The car belongs to the moderate price class, and is unique for its simplicity of construction and control. It is shaft driven, has two speeds and a reverse obtained on the sliding system, and is powered with the popular type of four cylinder motor.

This motor has a bore of 3¾ inches and a stroke of 4 inches, and, as will be seen from the following description, is large enough to furnish ample power for the car. It is of the block type. All the valves are on the right hand side. Inlet and exhaust manifolds are cast separately to simplify the foundry work on the cylinder unit. They are attached in the conventional manner. The crank case is of the barrel type, with a liberal hand hole at the bottom for connecting rod adjustment. This opening is

This combination gives a powerful pressure on the discs, is self adjusting and may be operated by a very slight foot pressure. Small springs made integral with the discs hold them apart when the clutch is disengaged. A clutch brake is also provided.

The two speed and reverse sliding change gear is contained in a compact cone shaped case bolted to the flywheel case and forming the rear end of the power unit. The gears have wide faces. Direct drive is by an external internal gear clutch. The shafts are mounted on ball bearings. The shaft for the sliding pinions is provided with four feathers.

At the rear of the change gear case is a single universal joint; it is surrounded by a globe joint, which connects the propeller shaft housing tube to the frame. On the lower side of the case for the globe joint are two sockets which fit the ball ends of struts which connect with the outer ends of the rear axle housing. New Departure ball bearings are used on the inner ends

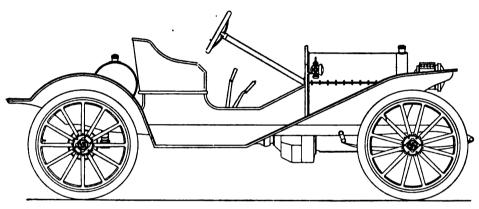

is given as 1,250 pounds. Two side and one tail oil lamps, a horn, tire repair outfit, and tool kit are furnished as regular equipment.

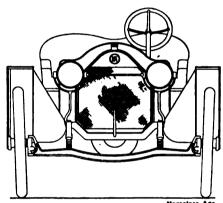

Three styles of bodies are furnished: A two passanger runabout, with tank on the rear deck, selling at \$800; a runabout body, with single rumble seat, at \$825; a surrey body, for four passengers only, at \$850. In the surrey both front and rear seats are divided, so only four passengers may be carried. This is done to prevent overloading, five or six passengers often being carried in cars with continuous seats which are intended for four.

#### Connecticut Master Vibrator Coil.

This type of coil is built on what is known as the master vibrator principle, using but one vibrator, which produces the electrical interruptions in the Rhumkorff windings.

With the ordinary type of spark coil, employing one vibrator for each coil, it is necessary to adjust each vibrator independently, and unless they are adjusted so as to

SIDE ELEVATION AND FRONT VIEW OF KRIT RUNABOUT.

closed by a sheet metal cover. The crank is of the two bearing type, large annular ball bearings being used. The crank pins are exceedingly liberal for a motor of this size, being 134x134 inches.

Cooling is by the thermo-siphon system, using a vertical tube radiator with continuous fins, and very large hose connections. The fan is 16 inches in diameter and is driven by a very wide, flat belt. It is mounted in such a manner that it may be raised to adjust the belt tension.

Ignition is by Bosch high tension magneto without spark advance. Lubrication is by splash. The flywheel is at the rear of the motor, and is fully enclosed. As it revolves it dips in an oil pool and carries the oil to the top of its case. From this point it flows into pockets cast in the crank case, and lubricates the various bearings. Cylinder walls are lubricated by splash. The breather pipe is attached to the case for the timing gears, and its action furnishes lubricant to their faces.

The flywheel contains the multiple disc clutch. This clutch consists of comparatively few discs of saw steel. They are pressed together by a 60 pound spring, which acts on a cone that communicates its motion through toggle levers to the discs. of the axle shafts and Hyatt roller bearings at the wheels.

The front axle is an I section drop forging, with Elliott type knuckles cross connected at the rear of the axle. The front wheels have cup and cone ball bearings. The front springs are nearly straight semielliptics. A single semi-elliptic spring, set crosswise, is used at the rear. It is placed in front of the axle with its ends linked to the brake housings, and its centre hinged to the rear cross member of the frame. The frame is of pressed steel, neither dropped nor narrowed. The power unit is supported at three points.

The driver's seat is on the left hand side. Steering is by an irreversible gear cross connected to the right knuckle. Gear shifting and emergency brake operation are by the usual hand levers, but the gear shifting lever is placed outside. The service brake and clutch are operated by a single pedal. The spark advance is fixed. The throttle is controlled in the usual manner. Both sets of brakes are of the expanding type, and operate directly on the rear wheels. They are fully enclosed.

The wheel base is 96 inches, and the tread is standard. The wheels are 32 inches in diameter, fitted with 3 inch tires. The weight

draw the same amount of current and are identical in construction and insulation, the results obtained from the different cylinders are anything but uniform. This condition is overcome in the master vibrator type of coil, for the reason that when the vibrator is adjusted to draw a given amount of current the adjustment is absolutely the same for all coils, with the result that uniform ignition is secured. It is claimed that the difference is so great in the majority of cases that it will be noticed immediately upon opening the muffler cut-out. It will be readily understood that there is but one vibrator to adjust.

On the top of each coil unit is located a cut-out button, the pressure of which will cut out any cylinder for testing purposes. In the individual vibrator type of coil the cylinders are tested by pressing down one or more vibrators, thus cutting off the spark. In the MV type this result is accomplished by means of the buttons above referred to. The master vibrator is so made that the contacts do not revolve in making adjustments.

The coil is made on the unit coil principle, and it is simply necessary to lift the unit from the case after removing the cover. which makes it exceedingly convenient in

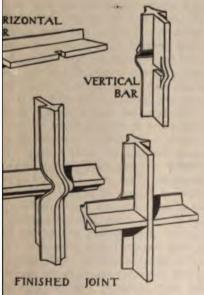

AASTER VIBRATOR CONNECTICUT COIL.

of test where it is desired to reverse of the units in the case. Each coil unit parated by means of a buckproof shield, h prevents the bucking effect due to age of current from one coil to any when the motor is pulling on a hill a heavy charge of gas. These coils manufactured under license of the Unit Company's patents, which are said to r unit, buckproof and master vibrator truction.

e vibrator unit is made in two styles, e and double. The accompanying ilation shows the double vibrator type, construction giving a spare vibrator h can be instantly brought into use by rsing the unit. Coils can be fitted with r plug, lever or magneto switch.

#### "Fenestra" Steel Sash.

me Detroit Steel Products Company, De-Mich., manufacture a steel window known as the Fenestra, which is pararly adapted for garages and factories, sash is made from special rolled stock material combining strength with weathesisting qualities, and is put together in interesting manner illustrated by the apanying cut. A small cross slot is in the vertical bar, only sufficiently to allow the flange of the horizontal to pass through; the molded portion is pressed out so as to fold closely around

FENESTRA STEEL SASH.

the molded portion of the horizontal bar. A small notch is made in the horizontal bar to act as a lock. It will be seen that in making one of these joints only a small amount of metal needs to be removed, and it is claimed that the section can be made much lighter than with a mitre joint. The peculiar section employed is claimed to insure 25 per cent. more light to a given opening than has been obtainable heretofore. The curved section is also claimed to give the sash a better appearance than that of the old mitre joint sash. The company have standardized the sizes of the sash for 10x16 inch and 12x18 inch panes. The use of these standards neither restricts the size of the window nor the percentage of ventilation which may be obtained from a given open-

#### The Foster Shock Absorber.

The Foster shock absorber is built so it acts free in the centre and binds gradually going up and coming down; it allows free play to the springs over smooth roads, and only takes effect where it is rough enough to be actually needed. The stationary base of the absorber consists of an oval shaped steel

FOSTER SHOCK ABSORBER.

cup, the length being a quarter of an inch greater than the width. This cup is encircled by a one piece bend of flexible spring steel, faced with a special prepared leather, which bears against the outer surface of the steel cup, thereby producing the required friction.

#### New Multicylinder Car.

A twelve cylinder car has been built by George Schebler, of Wheeler & Schebler, Indianapolis, the car being designed to try out some of Mr. Schebler's ideas. The cylinders are 31/2 inch bore by 4 inch stroke and are cast single, being arranged six on a side at an angle of 30 degrees. The cylinders are so coupled that the driver can cut six of them out at will without changing the gear. Thus, in running with six cylinders the additional six can be put in action if the car is in a ditch or on a particularly bad bit of road. In building the car Mr. Schebler used a Marion chassis and body, adding eight cylinders to the four of the Marion car. The twelve cylinder car is rated at about 75 horse power and has proven satisfactory in speed and hill climbing tests.

VASCO WIND SHIELD.

#### New Vasco Wind Shield.

The new Vasco wind shield is quite different from other makes, operating upon an entirely new principle. Friction discs instead of springs are employed, and the driver can tilt the upper half of the shield at any angle desired with one hand while the car is in motion. There is no awkward adjustment necessary to cause a quarter of an hour's delay when a storm suddenly comes up while on the road, and the fact that the shield can be easily tilted when the sun is at an annoying angle makes it especially desirable.

A noteworthy feature of this device is the "gap," by which protection from rain and snow can be secured and yet making a clear view ahead possible. The Victor Auto Supply Manufacturing Company, of 42 West Forty-third street, New York with a factory at Providence, R. I., are the active manufacturers and distributors of the Vasco wind shield.

#### New Type Connecticut Dash Coil.

A new type of dash coil, to be known as Type X, has been placed on the market by the Connecticut Telephone and Electric Company, of Meriden, Conn. This is a less expensive coil than their regular standard make, and is considerably smaller. It is made up on the unit system, with the exception of the one cylinder style, which is of the solid type. All units are removable and interchangeable without changing a wire connection. This coil is also fitted with one adjustment. The cases are mahogany, highly finished, and are fitted with type P, L or magneto switch as desired.

CONNECTICUT TYPE X COIL

# GREAT QUESTIONS OF AUTOMOBILE ENGINEERING.

# Unit versus Multi-Unit Cylinder Construction.

BY ALBERT L. CLOUGH.

In comparing the relative advantages possessed by the practices of casting motor cylinders in single units, pairs or blocks of three or four, it is well to remember that the use of single cast cylinders is an old and thoroughly accepted practice. Casting in pairs has also been common for a long time, and its adoption by manufacturers aroused very little comment upon the part of motor car users. Casting in triplets and quadruplets, or true block construction, is, however, of rather recent introduction. although much more familiar abroad than here, and the practice has aroused very great interest among automobilists. Casting four cylinders en bloc, as compared with casting in pairs, is rather a difference in degree than in kind; but for some reason public attention has seized upon the four cylinder block motor as an innovation of a radical nature, and has criticised it in the way that every novelty of a rather startling nature is criticised. In fact, block construction has been to a certain extent prejudged, and it is quite possible that some of the arguments arrayed against it, even before it was fairly adopted in this country, are of less weight than was at first supposed.

As set forth by its advocates, the primary advantages of including more than one cylinder in a single casting are reduction in engine bulk and weight and diminution in foundry and machine shop expense. These advantages are realized to a certain extent by casting cylinders in pairs, but in a much fuller degree by casting all the cylinders of a four cylinder engine en bloc and in casting the cylinders of a "six" in two sections of three each.

The reduction in bulk, or rather in engine length, comes about by bringing the cylinder walls of adjacent cylinders together, thus reducing the total length of the engine by the amount of the cylinder walls, water spaces and jacket walls which are dispensed with, namely, three cylinder walls, six water spaces nearly and six jacket walls. If the cylinder walls of neighboring cylinders are not brought together, but are separated by a restricted water space, the total length saved is somewhat more than three water spaces and six jacket walls.

The advantage pointed out as accruing from decreased engine length is that, with a given wheel base, there will be just so much more space available between the axles for the useful load, or, looking at the matter in the other way, for a given useful carrying space, the total chassis length may be reduced and its weight and cost somewhat decreased.

REDUCED WEIGHT AND BULK.

Reduced engine bulk means reduced weight in proportion as water and iron are dispensed with in the cylinder construction, and, of course, the crank case weight is decreased in a similar proportion. Diminished engine weight may permit a certain reduction in frame and running gear weight and will at least effect a constant saving in fuel and tires during the entire life of the car. It is further instanced as a merit of block construction that after patterns are perfected and founders are accustomed to the production of block castings the per cylinder cost of founding is much less with this construction than in the case of twin construction, and still less than with singly cast construction. The claim is made that considering the rough casting only the cost of the block of four is not over two-thirds that of four singles.

COST AND ACCURACY OF MACHINE WORK.

The per cylinder cost of machining a block of four cylinders is stated to be decidedly less than that of machining two pairs, and still less than that of finishing four singles, on the ground that multiple spindle boring mills can be used and fewer setting up operations are required in the case of the block, and not only is the machine work thus reduced but it is stated to be more accurate in the case of the block on account of the fact that all cylinders are bored at a single setting of the piece and parallelism of the bores is thus secured. As block construction favors the casting of the upper crank case section integrally with the cylinders-an expedient which is hardly practicable in single or paired practice-considerable machine work is said to be saved at this point.

Reduced manufacturing cost is, of course, of interest to the user, as it ultimately results in lower selling prices.

A further claim in behalf of block construction is that, since the whole engine is virtually one casting, a degree of rigidity unattainable in the single and paired construction is secured. Silent running and less vibration are the consequences, and it may be possible to reduce the weight of the crank case, since the stresses imposed upon it are much reduced.

#### INTEGRAL MANIFOLDS.

The intake manifold, being generally cored into the casting of a block motor, is thus water jacketed, and it is held that this greatly reduces the tendency toward condensation of the fuel and conduces to a more economical mixture with less liability toward carbonization. Whatever heat is taken by the mixture tends to reduce the temperature of the jacket water. The fact that there is but one mixture connection for all four cylinders, and a number of

joints in the intake system are thus avoided, is held to secure greater immunity from the development of air leaks.

But two water connections are required with the block motor, as against four in the paired construction and eight with the single construction (unless a series connection is adopted). This is held to make the block engine much cleaner in appearance and more free from troublesome leaks.

The water jacket space being a single one in the block motor it allows of very free water circulation, and is thus admirably adapted to use on the thermo-siphon system in which the circulating force is slight.

Reduced labor in assembling and dismounting is claimed as a virtue of the block motor, on account of the cylinder unit being in one piece and only two water and gas connections being required.

It is also pointed out that in a block motor using a single cam shaft a single plate may be designed completely to enclose all valve actions, shutting in the noise and lubricant and shutting out the dust.

Looking at this subject from the contrary viewpoint, the shortness of the block motor is adduced as a disadvantage in that it renders difficult or impossible the proper supporting of the crank shaft. In the form of block construction in which neighboring cylinder walls abut one upon another, the space for bearings within the block becomes exceedingly restricted, and the designer is forced to extremes in securing crank shaft support. The ball bearing is generally resorted to as being more effective per unit of length than the plain bearing. but it is a view largely held that this type of bearing is undesirable. Difficulties of a serious nature are met with in applying such bearings to the shaft-built up shafts, split bearings and other expedients being resorted to, or bearings of excessive diameter and high ball speed being adopted. Many persons believe that a five bearing shaft, such as is naturally used with the unit cast cylinder construction, is the preferable type, and such a shaft is well nigh impractical in a block motor of this type That it is even difficult to secure three adequate bearings for such a motor is the opinion of many disbelievers in block construction. The two ball bearing crank shaft is looked upon very much askance by a large contingent, despite the large number of these shafts which are giving good service. It is further pointed out that if a block construction is adopted which provides complete cylinder walls with water spaces between them, while the opportunity for more adequate bearings is afforded. much of the advantage of the shortness of

the block motor is sacrifieced. The answer of the "block contingent" to these aspersions regarding bearings is that their crank shaft is short in proportion to the reduced length of the motor, and transverse stresses are thus greatly reduced, and that the metal saved in the length goes far toward giving the shaft the "stubby" character which reduced bearing provisions demand. They point to what they consider highly successful crank shaft service on a large scale under their various bearing constructions.

#### LOSS OF CASTINGS.

In regard to the production of four cylinder blocks, it is adversely stated that on account of the excessive complication of the work defective castings are numerous and that not only is there a serious waste in the foundry but that there is a large waste of labor in machining castings which do not exhibit defects until well along toward completion. In reply to this criticism it is pointed out that manufacturers who have adopted block construction have generally adhered to it, and that new firms are taking it up.

Another common criticism against block construction is that in case of an injury to one cylinder, such as a scoring of the walls. the whole block of four has to be replaced, while one scored cylinder of a pair requires the replacement of the pair only and a damaged "single" requires the renewal of that cylinder only. In reply to this objection the manufacturer of block motors quotes a price for the complete cylinder block which he considers compares favorably with the prices charged by other makers for pairs and singles, everything taken into account, and he further remarks that many cylinder accidents, such as freezing and lubrication failures, commonly involve more than one cylinder.

#### UNEQUAL EXPANSION.

The advocate of casting cylinders singly very properly suggests that the expansion of one of his cylinders, under heat, has no effect upon any of the others, since they are entirely separate, and those using the paired construction point out that the expansive effects of only two cylinders are interrelated, but that in the block motor there are four cylinders inseparably connected which are hot at their tops and cool at their lower portions, and that the tendency is for the block to increase in length at the top and throw the cylinder axes out of parallelism. (See article by F. E. Watts, p. 513, Vol. 22, of this journal.) Not only so, but in case one cylinder fails to ignite for any length of time it remains relatively cool, and the cylinders on each side of it transmit to it stresses which deform it. In answer to this latter point it is claimed that, as all cylinders are subjected to the same mass of freely circulating water, the temperatures of all tend to be equalized thereby.

The fact that all the cooling water of the block motor is in a single communicating space lays this construction open to the objection that the flow is likely to be indefinite and given to eddies and that it is not so easy to direct the current upon the spots which specially require an active circulation, the result being excessive heating and distortion at these critical points. In refutation of this claim it is remarked that with the thermo-siphon system, as commonly used with these motors, and a design which effectually prevents steam pockets, the flow is automatically most active at the hottest spots and only slight temperature differences develop.

In block construction in which there is no water space between adjoining cylinders it is claimed that these lines of unjacketed wall space become very hot and that an excessive amount of oil must be supplied to make up for the thinning of the lubricant at these points and the distortion which there occurs.

#### CHARGE DISTRIBUTION.

The point is made against the practice of cored in gas passages that charge distribution is not so good as with the external pipe arrangement of special form and that the rough internal surfaces of the cast gas passages tend to throttle the entering charge at high speed to a greater degree than the smooth internal surfaces of the tubing used in other types of engine.

#### Automobiles in Java,

Java, the Dutch colony, is becoming a considerable market for automobiles. The imports of automobiles into the island were first separately enumerated in 1903, when they amounted to 32,086 guilders. During the following years the value of these imports rose rapidly, as is shown by the following figures: 1904, 60,860 guilders; 1905, 118,765 guilders; 1906, 219,231 guilders; 1907, 905,662 guilders. During 1908 the value of the imported cars undoubtedly considerably exceeded 1,000,000 guilders.

One of the factors which tend to promote the use of automobiles in Java is the fine road system constructed by the Colonial Government, and another the wide area of the cities, whose transit facilities have only as yet been slightly developed. This applies particularly in Batavia, whose white and colored population numbers 10,000, and which covers an area of 6 square miles. Owing to this condition the European families living in that city have always considered a light vehicle a necessity, and at the present time Government officials, merchants. physicians, planters, factory managers and even a considerable number of wealthy Chinese are substituting the automobile for the horse. The most popular type of vehicle is the four cylinder, double phaeton of 10-15 or 12-16 horse power, which sells at about 4,500 guilders. The four cylinder type of vehicle is preferred because it surmounts the hilly roads of the country with ease. It is possible to build the body in Java, but up to the present it has been customary to import the vehicles complete, owing to the fact that bodies of European design and workmanship are of more pleasing outline and more perfect finish than those constructed in Java with the aid of Chinese labor. Motorcycles are not sold to any extent, although recently the so called Moto-sacoche wheel is successfully being introduced.

In order to introduce automobiles on the market in Java it is advisable to establish an agency in Batavia, with sub-agencies in Samarang and Soerabaya. Cars of the best selling types should constantly be kept on hand at these agencies, as well as repair parts, and a repair shop should be maintained. Another possible method is to place an agency with some existing firm possessing a repair shop.—Belgian Consular Report.

#### Kansas City Show Balked.

It is now doubtful whether the show planned for Kansas City next spring will be held. At a smoker given by the Motor Dealers' Association at the Hotel Baltimore on November 6 five of the leading dealers of the city positively declared against the show, owing to dissatisfaction with the spaces assigned to them last year, and also because they hold that the demand for cars in that territory is so great at present that they can easily sell their respective allotments without a show. Those who voted against the show were the representatives of the Ford Automobile Company, Buick Automobile Company, Hathaway Electric Car Company, C. L. Taylor Motor Car Company and Maxwell-Briscoe Motor Car Company. Two other important firms were non-committal. In spite of these dissensions the following committee was appointed to select a show building and make the necessary arrangements for the show: E. D. Anderson, Henry Bruenning, Walter McGee, J. R. Histed and J. Frank Witwer. Another meeting will be held shortly.

#### New Valve Grinding Compound.

A new substance recently put upon the market with the idea of saving motorists labor and money in valve grinding is being manufactured by the Victor Auto Supply Manufacturing Company, 42 West Forty-third street, New York, and is known as Vasco Grindine compound. Grindine has been prepared to eliminate the dangers of emery, and is claimed to do it most efficiently. The abrasive in the compound is an electro-chemical product, and was selected for its extreme hardness, sharpness and temper. The binder used has a high viscosity, and is claimed to produce a smooth, even surface. It is conveniently put up in collapsible tubes, both coarse and fine, and remains at the right consistency. One of the chief virtues is said to be that it does not waste away or drop into the cylinder during the process of grinding, and, besides this, it cuts quite rapidly.

# COMMENTS AND QUERIES OF READERS.

# Valves in Cylinder Heads. Editor Horseless Age:

I am a subscriber of your valuable paper and have read it for a number of years. Five years ago I built a four cycle marine motor with two cylinders, valves on opposite sides, bore 6 inches, stroke 7 inches. It has always run and is as good today as ever. I am going to build a four cylinder motor of the same bore and stroke, but I prefer to put the valves in the head of the cylinder, feeling that I can get more power by exploding the entire charge directly over the piston. I cannot see the advantage of exploding about one-half of the charge in the valve pockets. There should be no difficulty in keeping the exhaust valve cool, as the water can be introduced directly over the exhaust outlet. Is there any objection to my theory?

Considering the stroke, would 35 per cent. of same give me 65 pounds compression?

G. F. S.

[If you place both valves in the cylinder heads you will get slightly more power than if you placed them in pockets at the sides of the cylinders. As we understand that the motor is to be used for marine purposes, we presume that you will make the heads detachable, in which case the valve seats can be directly in the head castings and need not be in cages, as would be required if the heads were cast integral with the cylinders. With the valve seats in the heads directly they can be perfectly water cooled, and there is no more danger from overheating them than if they were located in side pockets. On the other hand, if the heads are to be made integral and the valves located in cages, it is somewhat difficult to keep the exhaust valves cool in a motor of this large size if it has to run continuously under full load.

A compression space of 35 per cent. of the stroke should give you about 72 pounds gauge compression.—Ep.]

#### Rotary Motors.

Editor Horseless Age:

I would like very much to know the source of the gentleman's information on rotary aeroplane motors as to their being scrapped.

At present the world's records for duration and length of flight are held by rotary motors, in fact by the same motor, the "Gnome," similar to that described by you. The new type now being evolved has the propeller blades attached to the head of the cylinder.

This type of engine apparently has a great future before it. I would also like to know the "unsolved problems" connected with rotary engines—there are none that I know of and I have been engaged in their study for about six years. There are slight dif-

ficulties to be overcome, but they are still present in the automobile motor of the present day.

Standard sizes of rotary engines are for sale in France and England today, and some experimental work has been done with them for rigid dirigibles, as per sketch.

W. G. MARTIN.

[As our correspondent who made the inquiry about the rotary motor is located in Switzerland it will be some time before an answer regarding the source of his information can be expected from him.

One of the most difficult problems in connection with the rotating cylinder motor is undoubtedly that of lubrication. It will be observed from the test results of the Gnome motor that the oil consumption was one-half the fuel consumption, whereas in ordinary motors the oil consumption is only about one-twentieth the fuel consumption. We understand that during the Rheims week Farman's plane constantly left an oil smoke trail behind. Other unsolved prob-

lems in connection with rotary motors were mentioned in The Horseless Age of March 17, 1909.

In this connection we beg to point out that the rotary cylinder motor was first commercially developed in this country by the Adams Company, of Dubuque, Ia., who have been building automobiles with such motors for the market since 1904 and had been experimenting with this type of motor since 1898. The company last year built a number of aeroplane motors of this type.

—ED.]

#### Engine Braking.

Editor Horseless Age:

Enclosed find clipping relating to the use of the clutch in driving. I would like your opinion in the matter. I have always understood that it was the best practice never to brake against the engine, and therefore I invariably throw the clutch out when I put on the brakes to slow the car for bad crossings or water breaks in the road. Of course I try and use judgment in braking, and do not jam them on and slide my wheels. If I am wrong in this I would like your reasons for the use of the clutch as suggested by the Autocar. B. B. H.

[The article in the Autocar referred to recommends the use of the throttle wherever practicable when slowing down the

car instead of using the clutch for the pur-The advice is absolutely sound. If, when it is necessary to slow the car, as when approaching a blind corner, you left your throttle in the same position and attempted to cut down the car speed by slipping the clutch, you would continue to generate the same power in your motor and use up the excess power in wearing out the clutch. If, on the other hand, you partially close the throttle you reduce the fuel consumption and the power of the motor in accordance with the requirement at the lower speed. When it is necessary to reduce the speed considerably in a limited time a complete closing of the throttle valve, as suggested in the article, is advisable, and the fitting of a valve which opens the cylinder to the atmosphere when the throttle is thus completely closed is a very good idea which has been championed in these columns on occasions, as it tends to cool the motor and prevents sucking an excess of oil from the crank chamber up into the cylinders. Such an air valve is particularly valuable where the car is often allowed to coast.

The brakes should in general be used as little as possible—the same as the clutch. and for substantially the same reasons. Where the car need not be stopped in a very short distance it should be allowed to come to rest of itself by cutting off all fuel from the engine, except where it is desired to start the engine again on the switch. Of course, where a quick stop must be made the brakes must be applied, and then the clutch should first be withdrawn (if this is not done automatically) so that the brakes need to kill only the inertia of the car and not that of the engine also.—ED.]

# Wire Gauze Screen in Inlet Pipe. Editor Horseless Age:

I have read somewhere that by inserting one or more screens of fine mesh wire gauze (about 100 to 110 mesh) in the intake pipe of a motor between the carburetor and cylinders there is a marked saving in the consumption of gasoline with a slight addition of power.

Will you kindly give me your opinion as to whether there would be any advantage in inserting the gauze as stated, and also if it would be likely to cause any trouble.

It would seem to me to be advantageous in preventing the carburetor catching fire from the popping back of an ignited weak charge, as it is well known that flame will not pass through fine gauze until the gauze itself is heated to a high temperature.

Any comments or information you can give will be greatly appreciated by your subscriber.

A. L. M.

[The gauze screen might have some effect tending to make the charge more

homogeneous, but we do not believe that the effect on the fuel economy and the power would be appreciable. In fact, unless you make the fitting containing the wire gauze very large, so that the aggregate cross section of the openings in the gauze is materially greater than the cross section of the inlet pipe, the screen would have a throttling effect and reduce the maximum power of the motor. Such a screen will prevent back firing in the carburetor, but it seems to be the general opinion that it is not needed for this purpose. It is better to keep your carburetor properly adjusted, and no back fires will occur.—Ep.]

#### Calculation of Chassis Springs-Correction.

Editor Horseless Age:

In the second instalment of the article on "Calculation of Chassis Springs" there should be a figure one (1) in place of the lower case 1 in equation (3). This error is evidently due to the use of the same typewriter character for the letter 1 and the figure 1.

ASHER GOLDEN.

#### Queries.

Editor Horseless Age:

Could you find space in your journal to answer the following?

In the second column on page 407 of your issue of October 13 you state that the two cycle motor lends itself less to air cooling than the four cycle. Is this so, or is it a printer's error, as another motor journal repeatedly stated that the two cycle should be easier to cool than the four cycle?

Are the successful Elmore engines two or three port, and can you give the approximate sizes of the ports; also the bore and stroke?

Can you briefly sum up the working advantages and disadvantages of the two cycle as compared with the four cycle, assuming an equal number of cylinders of the same bore and stroke?

Some years ago a friction transmission, as shown (very much exaggerated) in the accompanying drawing, in which there are two large friction discs and two rollers on two short shafts, with final chain drive, was very much advertised. Do you know why this type is not a success, and can you state why the friction drive is not more in favor? What are the advantages and disadvantages of the system?

[Whether it is more difficult to cool a four cycle or a two cycle motor is, of course, a matter of opinion. With the four cycle motor you encounter one set of difficulties, and with the two cycle another rather different set. With the four cycle motor the most difficult problem is to keep the exhaust valves at a sufficiently low temperature. This difficulty is not met with in the two cycle motor, as it has no exhaust valves. On the other hand, owing to the fact that there is an explosion in each cylinder of a two cycle motor at each revolution of the crank shaft, the cylinder walls of a two

cycle motor are in contact with hot gases during practically twice the proportion of the time as the walls of a four cycle motor. and you do not have the intervening inlet stroke to cool the cylinder walls. There is absolutely no doubt that more heat must be disposed of per unit of cylinder wall area in a two cycle than in a four cycle motor. Another difficulty that you encounter in attempting to air cool a two cycle motor is that because the exhaust ports are usually on one side of the cylinder and the inlet ports on the other, the cylinder is heated and expands unevenly, and it is quite difficult to keep the cylinder wall in the vicinity of the exhaust port at a temperature permitting of continuous lubrication. It would be interesting to hear from a number of those who have had experience with air cooled two cycle motors as to the relative difficulty of air cooling the two types.

The Elmore engines are of the three port type. Last year the company built motors with cylinders of 4½ inch bore and 4 inch stroke. We do not have the port dimensions of these motors.

The advantages and disadvantages of the two cycle motor will be discussed in an article in an early issue.

If we remember correctly, the firm which
